SIR,—It was my wish in youth to practise as a physician, and I therefore requested my parents to send me to the University of Edinburgh, that I might graduate there in the Faculty of Medicine. Now, my father, being a general practitioner in a small country town, and having practised all his life with the M.R.C.S. and L.S.A., wished me to succeed him and to take the same diplomas. The consequence was, I was sent to a provincial school of medicine; and two years before I was qualified to practise, my father died. I was unable to succeed to his practice, and it was therefore sold. In course of time I took the L.R.C.P. Edin. and L.S.A. Lond., and commenced practice for myself in a large town. I did not, however, like general practice; but of course I have been obliged to stick to it, and I have obtained a fair amount of success. I could, however, have done much better if I had had a degree of M.D. in addition to my present diplomas, for many appointments are only given to graduates of British Universities, and the public know well that an University man ranks higher than a mere Licentiate or member of a College. In consequence, his advice will be oftener sought after, and he will be able to take a higher fee. It is a hard case for me, and for hundreds like me, who have not had the choice of education in early life, and who are in possession of legal diplomas, that we should be unable to offer ourselves for examination (without residence) at a British University. I in common with others have had four full years of medical study, have been in practice over six years since, and have kept up my knowledge of medicine and other subjects in addition, yet there is not a portal open for the coveted degree. I would propose that a petition be offered to the University of Cambridge, praying for medical practitioners of five years' standing, and who have studied at some medical school for four years, to be admitted to the examination for the M.B. degree, and then, after the lapse of one year, to another examination for the M.D. degree. The preliminary examinations of other bodies should be accepted in place of examination in Arts or matriculation. I mention Cambridge for this reason: the University has shown itself of late most anxious to diffuse knowledge all over the country, and has established lectures in various large towns under what is known as the Cambridge University Extension Scheme. Again, the University proposes to admit all medical practitioners to its examinations in "public medicine". It has shown itself willing to do right and to act justly. Surely if sufficient pressure could be brought to bear upon the authorities, we should soon be admitted to degrees without residence. I hope this subject will be taken up, and a petition be set on foot to the University authorities; and if once a door is opened, we shall hear no more of the vexed titles of "Dr.", "M.D.", etc.—I am, sir, yours faithfully,
JANUARY 1875.

ONE WHO WOULD LIKE THE M.D. DEGREE.

SIR,—As this subject is again being ventilated in your columns, perhaps you may be able to find room for the following remarks, which may elucidate some of the points under discussion.

"The Charter of William and Mary, and the Act of the Irish Parliament 1 Geo. III. cap. xiv. made perpetual by the Act 3 Geo. III. cap. xiv. s. xi. confer on the Fellows and Licentiates of the King and Queen's College of Physicians the title of Doctors of Physic." Here, then, we are on firm ground, Licentiates of the Irish College having legal right to the prefix "Dr." The London College, while at one time sanctioning, now forbids the assumption of the title by its non-graduated Licentiates, though I am not aware of any case in which this bye-law has been put in force. The Edinburgh College steers a middle course, and neither permits nor forbids, but states "that some name must be found for non-graduated Licentiates of a College of Physicians, shorter and more conveniently distinctive than their legal designation; and if it be not formally arranged by the Colleges what that name is to be, the public and the profession will take the matter into their own hands, and will establish an usage overriding all formal objections that may be taken to the employment of one or other of these conventional titles."

The *Lancet*, when referring to the year of grace, has the following. "The Council of the Royal College of Physicians of Edinburgh are just now fighting the battle of common sense in the profession. They have taken up the sword for the *plebs*, and if they wield it manfully, and with frank and valorous mien, there can be no question of the result. They have offered to the general practitioner of the United Kingdom a means for placing himself on a professional level, as far as title and degree can go, with the magnates of the profession." No Licentiate of a

College of Physicians would think of denying the right of Doctors of Medicine to call themselves physicians. Why, then, should graduates be so sore on the point of Licentiates prefixing "Dr." to their names? and yet there are, perhaps, as good legal grounds for calling the former in question as the latter. If the question "Are you a physician?" were asked of a Doctor of Medicine, he would, I think, answer in the affirmative; but if the question were, "Are you a Licentiate of a College of Physicians?" he could not so answer. So it would be with a Licentiate: Are you a Doctor? Yes. Are you a graduate? No.—I am, sir, faithfully yours,
JANUARY 1875.
A PHYSICIAN.

MR. UNDERHILL.—Yes.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Gazette; The Western Daily Press; The Manchester Guardian; The Ulster Advertiser; The Sussex Coast Mercury; The Broad Arrow; The Surrey Advertiser; The Bedale and Northallerton Times; The Hackney Express; The Liverpool Porcupine; The Scotsman; The Liverpool Mercury; The Glasgow Herald; The Stroud News and Gloucestershire Advertiser; The Bradford Observer; The Morpeth Herald; The Portsmouth Times; The Western Daily Press; The York Herald; The Sheffield Evening Star; The Brighton Guardian; The Sussex Daily News; The Wrexham Advertiser; The Newton Directory; The Sussex Coast News; The Berkshire Chronicle; The Hull News; The Southern Times; The Worthing Intelligence; The Hampshire Telegraph and Sussex Chronicle; The Sheffield Daily Telegraph; The Hereford Times; The High Peak News; The Brighton Daily News; The Bath Argus; The Pembroke Herald; The West Briton and Cornwall Advertiser; The Glasgow Herald; The British Mail; The Indian Medical Gazette; The West Country Lantern; the Ripon Gazette; etc.

COMMUNICATIONS LETTERS, ETC. have been received from:—

J. BURDON SANDERSON, M.D., V.P.R.S.,
Jodrell Professor of Physiology in University College, etc.

LECTURE II.

CHANNELS BY WHICH BACTERIA MAY ENTER THE ANIMAL ORGANISM.

IN the bodies of men and of the higher animals, there are innumerable doorways by which particles as small as septic bacteria must constantly enter, yet no putrefactive changes occur. Bacteria, as we have seen, are, if I may so express myself, potentially present in all articles of food; for every kind of ordinary liquid has the faculty, when added, even in the smallest proportion, to a "cultivation liquid" (*i. e.*, a liquid fitted to serve as soil), of determining in it at once the development of bacteria. The fact that, even when we employ the highest powers of the microscope, we can see absolutely nothing in these liquids, only teaches us that our modes of observation are insufficient: for we have the proof, not merely that they act zymotically, but that we can deprive them at will of this power, either by heat or by agents such as carbolic acid, which are destructive to bacterial life. Thus, in ordinary drinking water, in cold meat, in fresh vegetables, in cheese above all, and in all ordinary specimens of milk, we are constantly taking in efficient sources of saprogenous life.

When such aliments come into relation with the absorbing apparatus of the intestine, whatever of course is chemically soluble enters the blood-current by the veins, while the insoluble parts enter the lymphatic system by the villi. The mechanism of absorption by the villi is such that even inorganic solids, in a state of fine division, are very readily taken in, and thus find their way from the intestinal cavity into the lacteals, through the thoracic duct, into the blood-stream. Anatomically, this was formerly very difficult to understand; for, so long as it was supposed that the epithelial covering of the villi was set on a structureless hyaline basement-membrane, it was difficult to see how particles could pass through such a membrane. Now we know that this membrane is not structureless, but that here, as in other examples of supposed structurelessness, the substance is penetrated by channels lined with protoplasm, which in the one direction are ready for the taking in nutritive particles, especially oleaginous ones, and in the other communicate with the commencing lacteal.

But, before these anatomical conditions were known and understood, it was proved experimentally that solid bodies in a state of fine division readily entered the lacteals. It is a great many years since Oesterlen showed that, if charcoal in extremely fine powder were mixed with the food of animals, the particles could afterwards be found in the circulating blood. *A fortiori*, therefore, if bodies relatively so enormous as charcoal-particles can be taken into the blood-stream by the villi, bacteria must certainly get into the vascular system whenever they are present in the intestinal liquids. Yet, notwithstanding the ubiquitousness of bacterial germs, it is manifest that the chance of their entrance into the organism by the intestine must depend in a considerable degree on the quality of the food, and particularly on its liability to septic change, and on the readiness with which its constituents are absorbed. Of these two conditions, the latter is likely to be the more influential.

Those alimentary substances which are soluble, as has been already said, enter the circulation by diffusion—a process which would exclude even particles so small as bacteria. But the fatty constituents can only obtain admission by interstitial channels, such as those which form the beginnings of the lacteal absorbents in the intestinal villi. Hence we are led to anticipate that a liquid like milk, of which the oleaginous particles are of extreme minuteness and in enormous numbers, all of which enter the absorbent vessels without undergoing any chemical change, would have a better chance of serving as a vehicle for saprogenic germs than any other sort of food. Whether this is so, is still a matter of speculation. It is supported by what was ascertained

in the inquiry relating to the remarkable epidemic of typhoid fever in London last year. With reference to that epidemic, it was, I think, clearly shown that the spread of typhoid was due to a widely spread contamination of a certain supply of milk; but it was not shown what was the nature of that contamination.

Notwithstanding the trouble that was expended in the research, it cannot be admitted that a case was made out in evidence of its specific origin—*i. e.*, its origin from previously existing cases of typhoid fever. This question must, I think, be allowed to remain open. For my purpose, it is sufficient that it was contaminative, and that the contamination had a very wide distribution. For if this be admitted, a practical lesson may be learnt from it—*i. e.*, that, if it happened once, it may and will happen again; and that greater precautions against contamination than are at present used are necessary. In England, we use our milk raw. In Germany, and in all countries in which acid fermentation products are consumed by the population, the milk is all boiled at the dairy before anything else is done to it; for, if it were not so, it would not be possible to produce sour milk without constantly running the risk of septic fermentation. It would pass through the stage of lactic acid fermentation into that of putrefaction. I have myself ascertained experimentally that it is not possible, as regards London milk, to keep it until it is acid without its becoming at the same time putrid. Sour milk, as used in Germany, is a refreshing and wholesome beverage, but a little leaven of septic bacteria is sufficient to deprive it of both these qualities, as any one knows who has attempted to prepare it from London milk.

The other doorway for the introduction of bacteria is the mucous membrane of the lungs. Experiment has proved that, in animals exposed to a smoky atmosphere, the black particles are absorbed by the mucous membrane, and can be traced step by step along the course of the absorbent channels. It was indeed in this way that the first step was made towards the acquisition of that knowledge of the lymphatic system of the lungs which has lately been brought to comparative completeness by the anatomical researches of my colleague at the Brown Institution, Dr. Klein; for it was by Knauff's experiments* on the effects of a smoky atmosphere on dogs that the manner in which smoke particles find their way through the pulmonary epithelium, and thence into the network of superficial lymphatics, that the course and distribution of these channels first began to be understood. In the pulmonary mucous membrane, we have, then, a second unguarded portal by which morbid particles can enter the animal organism.

GERMLESSNESS OF HEALTHY LIVING TISSUE.

These considerations lead us to another question, which lies nearer to the object we have in view in these lectures—the elucidation of the relation of bacteria to disease. From experiments made in 1871, I came to the conclusion, that the blood and tissues of healthy animals were barren: that is, that, when subjected to conditions of temperature favourable to the development of microphytes, no such organisms were developed in them, provided that they were protected from external contamination. The general truthfulness of that conclusion has been confirmed by better and more exact experiments than mine, so that "barrenness" may now be accepted, as regards muscle and blood, as a criterion of health. But, from recent experiments which have been made at Heidelberg under the direction of Professor Kühne,† and which I have lately repeated a good many times, following his method exactly, it appears that the negative property of germlessness is not one which belongs to all organs, and that, in particular, those parts of the animal body which are in closest proximity to absorbing mucous membranes are most liable to be found pregnant with microphytic life when tested by suitable methods. Kühne's mode of experiment is as follows. An animal having been killed by opening a large artery, the organ of which the germlessness is to be tested is rapidly exposed, and a small bit cut out with a sharp scalpel, to which a previously boiled silk cord is attached. The preparation is then, without a moment's loss of time, dipped in paraffin at 120 deg. to 130 deg. cent. (about 250 deg. to 260 deg. Fahr.), and immediately afterwards withdrawn, allowed to cool, and again dipped. This process having been repeated several times, it is finally plunged into paraffin at a lower temperature (52 deg. cent. = 125.6 Fahr.), and allowed to remain until the whole mass (which is contained in a paper box like that used by histologists for "embedding") is cool. The thread having been burnt away, the whole is covered by an additional layer of paraffin, and the cake is placed in the "warm chamber" at a temperature of 30 deg. cent. (86 deg. Fahr.). In this process, the surface-layer of the embedded bit of tissue is of course

* See my paper on Artificial Tuberculosis, in the *Report of the Medical Officer of the Privy Council for 1868*.

† Tielgel, Ueber Cocciobacteria septica im gesunden Wirbelthierkörper. (*Virchow's Archiv*, vol. lx, p. 453.)

cooked, *i.e.*, its albumen is coagulated, but the interior remains unaltered. If the tissue be germless, it remains free from organisms, and is found to be so when the preparation is examined microscopically after remaining four or five days in the chamber. I place before you several such cakes of paraffin, some containing muscle, others liver, kidney, or spleen. I cannot assert that any of them are free from organisms, but it is quite possible that that of muscle may be. As regards the others, I will answer for it that all are full of bacteria—bacteria, be it understood, of which the germs unquestionably did not enter after death—germs which existed and retained their latent vitality in the living tissue. Muscle and blood, if healthy, are germless; liver and spleen never are.*

The experiment I have been describing is by no means the only one by which it can be shown that blood and muscle are germless. As regards blood, the earliest is that of Professor von Recklinghausen, to which, as may be remembered, Professor Tyndall referred in his famous lecture on Dust and Disease. This consists simply in allowing blood to flow from an artery into a platinum capsule, which has been heated to redness and allowed to cool. It is then placed in a moist chamber, *i.e.*, a chamber of which the atmosphere is saturated, and kept at the temperature of the body, or rather below it (35 deg. cent. = 95 deg. Fahr.) The blood so kept remains without putrefaction for months, if protected from contamination. The coagulum first formed disintegrates; the colouring matter of the corpuscles leaves them, becomes dissolved in the liquor sanguinis, and crystallises, if crystallisable; but, after this, no further change occurs. This method has been improved and modified by Klebs; for in the form originally devised it often fails.

Instead of using a capsule, he employs a glass tube of the same nature as the one exhibited at last lecture. When it is desired to collect a specimen of blood, the drawn out end of the tube is introduced into a vein and secured in its place by a ligature. This done, the point (which is of course within the vein) is seized by the thumb and finger and broken off. The tube being half vacuum, the blood fills a great part of it. The tube is then withdrawn, and immediately closed hermetically. The specimens of blood thus collected may be kept for any time without undergoing putrefactive change. If the blood of animals whose colouring matter is readily crystallisable be used, and the temperature be suitable, the liquid in the tube contains crystals of hæmoglobin. Most of it, however, undergoes a peculiar change, which results in the production of an amorphous coloured mass, differing from hæmatin in its insolubility in alkalies.

The other method—that of cultivation—was employed by Dr. Ferrier and myself in our original experiments in 1871. It was by it that the fact of the absence of the septic ferment in the blood was first established. Having found that all exposed liquids possessed what I then called the zymotic property—that is, the power of starting the development of *Bacteria Termo* in Pasteur's liquid—we extended our inquiries, not only to other animal liquids, but also to healthy tissue, and concluded that all the liquids and tissues of the body are germless.†

RELATION BETWEEN SEPTIC PROCESSES AND THE PRODUCTION OF FEVER.

We must now apply ourselves to the consideration how far the organisms with which we have been occupying ourselves have to do with the processes of disease. As I said, the inquiry must be approached from the pathological side. As naturalists, we may be interested in all the lessons to be learnt from bacteria: in studying the remarkable influence of the conditions under which they originate and grow, in modifying their form, or the question how they come into existence, as it were, out of nothing. But all this is beside the mark; at all events, beside our mark as pathologists. To us, who are concerned about disease, and have its prevention and cure as our ultimate

* It is desirable to note that in the experiments I have myself made with reference to the germlessness of muscular tissue, that of the dog was used. In substituting muscle of the rabbit, I have failed. I believe this stands in relation with the observed proneness of the latter animal to traumatic infection as compared with the immunity of the former.

† Under conditions not as yet sufficiently known, organic forms, probably allied to bacteria, are met with in the blood of healthy persons. About three years ago, a discovery was made simultaneously by Dr. Ferrier, and by Dr. Löffler of Vienna, that in certain individuals bodies exist in the blood which in form resemble sarcina. They are to be found in blood which has been received into calcined tubes with all the necessary precautions. If such tubes are kept at the temperature of the body for a week or two, they are found to multiply rapidly. This observation has been confirmed by Colin Heitridge, *loc. cit.*, p. 223. A still more remarkable observation was made by Dr. Osler in my laboratory two years ago. He found that in the blood of certain apparently healthy persons, peculiar aggregations of pale particles of extreme minuteness, but definite form, existed in considerable numbers. These were studied under the microscope, on a stage of which the temperature was maintained at 38 deg. (about 100 deg. Fahr.), and exhibited a series of changes, all of which are carefully figured in his paper (*Proceedings of the Royal Society*, No. 153). In short, each aggregation resolved itself in the course of half an hour or an hour into individuals, each of which possessed the power of active locomotion.

object, the subject loses its interest the moment it becomes unconnected with bodily disorder. Life is short, and the work to be done long and difficult. We must, therefore, keep close to our own subjects, if we wish to make progress.

There are three sorts of diseased processes in which bacteria are supposed to be concerned: the process of fever, certain processes dependent on inflammation, and the various processes of specific infection. The relation of the development of bacteria to the febrile process can be investigated experimentally; for liquids are within our reach that have this property, *viz.*, when introduced in a very small dose into the circulating blood of a living animal, they produce fever—a fever which derives its claim to be so called not merely from its being attended with rise of temperature, but from its consisting of the successive stages which go to make up a febrile accession or attack; *viz.*, a period of latency, a rigor with rapid rise of temperature, followed by loss of muscular power, and a period of decline, the whole process being of short duration—not more than five or six hours, and not being accompanied by any local disease whatever, but being throughout a blood-process.

The liquids in question are exclusively derivable from one of two sources; *viz.* (a) products of inflammation, (b) products of putrefactive decomposition of blood, muscle, or other animal tissues. I shall speak of them as pyrogenic liquids. Among inflammation products, those of serous and catarrhal inflammations are the most frequent sources. As regards the former, *i.e.*, liquids of serous inflammations, those are most active which are of infective origin, *i.e.*, those of which the producing processes are secondary. Of catarrhal products, there is one which has been used by Senator, and which I have also used myself as a source of pyrogenic material. I refer to the expectoration of the purulent stage of phthisis. From this liquid (which is of course always to be had in any quantity), an extract can be obtained by treating it with two per cent. solution of common salt, which admits of filtration. This extract is always pyrogenous.

It is to be noted first that all of these liquids are apt to contain bacteria; they are not, however, putrid in the ordinary sense; the last mentioned, for example, retains the peculiar odour of purulent expectoration; and, secondly, that all of them are more active when freshly prepared than at any subsequent period. If, *e.g.*, they are subjected to the temperature suitable for putrefaction, they very rapidly lose their activity, and the rate at which this occurs varies with that of the putrefactive process. This must not be understood to mean that they were not at first in a state of decomposition, but simply that the *pyrogen* (as we may, for shortness, call it, whatever its chemical nature) is a product which is produced at an early stage in the septic process.

But there is, as I have said, another source from which pyrogenous material can be derived, *viz.*, from any animal liquid or tissue in the early stage of septic decomposition. The favourite tissue for the purpose is muscle. If a quantity of muscle be chopped up and placed in water at a temperature of from 60 deg. to 70 deg. Fahr. for a couple of weeks or so, an infusion is obtained which is pyrogenous. The exact period at which it acquires this property depends on various conditions, more than all on temperature. If this period be allowed to go by, the pyrogenous activity declines, while the obvious signs of putrefaction become more apparent. If the extract be used in the crude state, the result of introducing it into the circulation is often rapidly fatal. The reason of this is that embolism occurs. Little plugs are formed which find their way into the pulmonary artery and produce sudden death. Even if the liquid be strained, the production of fever (the effect which at this moment interests us) is not the only one which presents itself. Local effects are produced of the class to which I have applied the term secondary inflammation, *viz.*, infective nodules in the internal organs—serous and mucous inflammation. Those animals which are prone to tuberculosis become, in consequence of such an injection, eventually tuberculous, although at the time they may apparently recover from the immediate effects. These effects—all of which must be regarded as in so far embolic that they are dependent on the circumstance that the liquid contains particles of irritating material which are carried by the blood-stream to various parts of the body, and there prove foci or centres of infective inflammation—have evidently no necessary connection with fever in the sense in which we have agreed to use the word, *viz.*, as consisting in rapid augment of temperature, attended with the characteristic muscular phenomena of rigor, followed by adynamia, and succeeded by a much more gradual decline.

It may, however, be possible by suitable methods to obtain this purely pyrogenic effect without the others. In other words, there may be in muscle-extract, at an early stage in the process of putrefaction, a substance which possesses the pyrogenic activity without that of producing secondary inflammation.

Before proceeding to state what others have done, and what I have

done myself, in the effort to find such a substance, let me draw your attention to the remarkable fact that no therapeutical agent, no synthetic product of the laboratory, no poison, no drug is known which possesses the property of producing fever. The only liquids which have this endowment are liquids which either contain bacteria or have a marked proneness to their production.

Further, let me remind you that, whatever effort we may make to discover a disease-producing agent, we must take, both as our starting point and as our guide post, the one fact that we know about it, viz., its pathological action. For our problem is this. In a mixed liquid, we have reason to believe that a body exists which has the property of producing fever. Let us suppose that, by the use of appropriate chemical methods, we succeed in separating from it a crystalline principle which forms compounds of definite characters and constitution. To us this is of no value, unless it can be shown that the body so obtained contains the fever-producing property. Or let us suppose that a certain organic form is present, and that, by appropriate methods, we can determine its botanical characteristics, it is of no interest unless it can be proved that the form encloses the property. It was from forgetting this principle that Hallier, whose indefatigable labours as a botanical investigator of the forms of vegetation which he believed to associate themselves with diseased products were referred to in the last lecture, lost his way. He forgot that, in the investigation of morbid agents, pathological experiment and observation are the only safe guides. His results are valueless, not so much because the botanists say they are wrong botanically, but because he went on developing form out of form, without ascertaining as he went along, by repeated experiments, that the clue he was following was the right one.

Let me now return to my own experiments. I will not weary you by detailing the steps by which I was led to adopt my present method, but will content myself with reminding you that the purpose is (assuming that, in all probability, the pyrogenous is separable from what has been called the "phlogogenic" action of the material in question, viz., the septic extract of muscle) to effect this separation by obtaining the "pyrogen" in a convenient form.

The plan is as follows. The liquid is first precipitated by absolute alcohol. The precipitate is separated by decantation, again extracted with boiling alcohol, and then filtered. The residue, after having been freed from alcohol by placing it *in vacuo*, is extracted with distilled water. The water extract is at once filtered. It is a limpid liquid, which, on injection into the circulation, proves to be pyrogenous. It contains 1.2 per cent. of solids. The dose required to produce a characteristic access of fever in a moderate sized dog is five cubic centimetres, that is, three-quarters of a grain of solid matter.

From this experiment, two conclusions suggest themselves—1. That the agent, of whatever nature, is soluble in water, insoluble in strong alcohol; 2. That it cannot consist of bacteria, or have anything to do with them. Both of these conclusions would be erroneous; and this leads me to what I regard as the kernel of the experiment, viz.: We have an apparently homogeneous and transparent solution which is pyrogenous. Are its constituents really in solution? Is it really homogeneous? If I had not from other experiments learnt that no "animal poison" is really soluble, I should have answered the first question unhesitatingly, Yes. To test it, we apply a method first introduced into pathological investigation by Professor Klebs of Prague—namely, filtration under pressure through porous cells. By applying this method, I obtain a second filtrate. I test it physiologically, and find that it is not pyrogenic. Pyrogen, therefore, is a substance which passes through filtering paper, but not through porcelain. Further, I find, on microscopical examination, that the first filtrate, although at first it contains no bacteria, is not entirely free from particles; and, if I repeat the examination after an hour, bacteria are present in considerable numbers. If I examine the second filtrate in the same way, even twenty-four hours later, it remains barren. The porcelain has, therefore, removed from the liquid, along with the pyrogenous agent, that on which the development of bacteria depends.

We can scarcely overlook the bearing of these facts on the question of the mode of origin of bacteria; for, considering that bacteria in their ordinary state are destroyed, as Dr. Bastian and others have shown, at the temperature even of boiling alcohol, and that, without reference to temperature, they are inevitably killed by immersion in absolute alcohol, it is clear that our fever liquid as used contains no active bacteria. It is equally clear that it contains that particulate material out of which bacteria spring, for otherwise it could not be deprived of its fertility by filtration. It must, therefore, contain particles which, although they resist alcohol and heat, yet are endowed with a latent capacity of development. I may add that the existence of such particles has been inferred on other grounds by mycologists, who have compared their condition to that of the winter-spores (*Dauersporen*) of the fungi.

LECTURES

ON THE

EXPERIMENTAL INVESTIGATION OF THE ACTION OF MEDICINES.*

By T. LAUDER BRUNTON, M.D., F.R.S.,

Assistant-Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; etc.

VI.—RESPIRATION.

Position of the Respiratory Centre: chiefly situated in the Medulla Oblongata, but extends also to the Spinal Cord.—Effect of Strychnia upon it.—Influence of Nerves upon it.—Influence of Vagus.—Vagus contains two sets of Fibres, Accelerating or Inspiratory, and Retarding or Expiratory.—Cause of Rapid Breathing in Pneumonia.—Influence of the Superior and Inferior Laryngeal Nerves.—Nasal and Cutaneous Nerves.—Local Action of Vapours when inhaled.—Action of Ammonia.—Methods of Registering Respiratory Movements.—Acceleration of Respiration by Drugs.—Is it due to (1) Excitement of the Voluntary Nerve-Centres, (2) Increased Temperature, (3) Increased Velocity of the Blood?—Increased Velocity may be due to (A) Prevention of Blood from reaching the Air: (B) Prevention of Air from reaching the Blood. Blood may be prevented from reaching Air—(a) By Stoppage of the Heart: Action of Quinine.—(b) By Embolism of the Pulmonary Vessels: Action of Coniivanga.—(c) By Contraction of the Pulmonary Capillaries: Action of Muscarina.—Observation of the Pulmonary Capillaries in the Frog under the Microscope.—Effect of Heat and Cold upon them.

It used to be supposed that the respiratory centre was not only situated in the medulla oblongata, but was confined to it. Legallois found that the cerebral hemispheres, cerebellum, and even a part of the medulla itself, could be removed without arresting respiration; and thus showed that the respiratory centre was either in the medulla or in the spinal cord. (*Expériences sur la Principe de la Vie*. Paris, 1830, tome i.) Flourens noticed that injury to a point named by him *nodus vitalis*, at the lower end of the calamus scriptorius, instantly arrested respiration, and thus caused death (*Comptes Rendus*, vol. xxxiii, page 437); and all experimenters have found that division of the cord just below the medulla also arrested breathing. These experiments seem to show most conclusively that the respiratory centre is situated in the medulla, and does not extend to the spinal cord; but the recent researches of Prokop Rokitsky (Stricker's *Medizinische Jahrbücher*, 1874, p. 30) on this subject show how careful we must be in drawing conclusions from experiments. Like all others, he has found that, under normal conditions, breathing ceases as soon as the influence of the medulla is destroyed by division of the cord just below it. But if strychnia be given to the animal, so as greatly to increase the excitability of its respiratory centres as well as of other reflex centres before the cord is divided, respiration will go on after the section has been made; and strychnia injected into the veins after the section will restore the respiratory movements, which the cut had arrested. This shows that the respiratory centre is not confined to the medulla, but extends into the spinal cord. The part contained in the cord is, however, too weak to keep up respiration alone under ordinary circumstances, though it can do so when its power is increased by strychnia. These remarkable effects of this poison give promise of future benefit from its use as a restorative in cases of death from drowning, etc.; but further experiments on animals are necessary before we dare employ such a powerful remedy in man.

Rokitansky's experiments enable us to demonstrate the presence of a respiratory centre in the spinal cord, as well as in the medulla of adult animals; but it is only fair to say that this was shown long ago by Brown-Séquard in the case of young ones. In young mammals and adult birds, he found that the thorax continued to execute rhythmical

* The request of a correspondent for a reference to Hering's experiments has, unfortunately, directed my attention to a mistake of some importance in my last lecture. I there stated that Hering found that respiratory movements ceased when arterialised blood was passed through the head and venous blood through the body; while, on the contrary, apyphical convulsions took place when venous blood was passed through the head and arterial blood through the body. I ought to have said that movements occurred in the blood-vessels such as would have taken place had the same sort of blood which circulated through the brain been passing also through the body. The experiments, however, were made on curarised animals, so that respiratory movements were impossible. Hering had previously ascertained that the arterial movements were synchronous with the respiratory movements, and might, indeed, be regarded as caused by impulses proceeding from the respiratory centre. They might thus serve as indications of the condition of the centre, where respiratory movements had been paralysed by curara. This paper is to be found in the *Wiener Acad. Sitzungsber., Math.-naturw. Classe*, vol. lx, Abth. 1, pp. 829-856.

respiratory movements for a short time after the cord had been divided transversely at the level of the first or second pairs of cervical nerves, so that there must needs be a part of the respiratory centre in the cord below that level (*Journal de la Physiologie*, vol. i, 1858, p. 223, and vol. iii, 1860, p. 153). Besides this, he considers that there are what we may term peripheral respiratory centres—viz., ganglia in the substance of the diaphragm itself analogous to those in the heart, which enable it to contract rhythmically after its connections both with the medulla oblongata and with the spinal cord have been destroyed (*op. cit.*, vol. ii, 1850, p. 115).

Although the excitement of the respiratory centre and the amount of work done by the respiratory muscles depend on the venosity of the blood in the medulla oblongata, yet this work may be differently distributed by the respirations becoming quicker but shallower, or slower but deeper, without the quantity of air respired being at all altered. This is effected by the action of various afferent nerves, of which the chief are the vagus, the superior laryngeal, and the nasal nerves; though others, such as the cutaneous nerves generally, have considerable influence.

Irritation of the vagus, or of its central end when divided, lessens the resistance in the respiratory centre, and quickens the respiration, but makes it shallower. Stronger irritation causes prolongation of inspiration. A very strong excitation annihilates the resistance in the centre, and causes inspiration to be almost indefinitely prolonged, so that the breathing is completely arrested.

The ends of the vagi in the lung are normally in a state of constant excitation, and therefore division of these nerves renders the respiration slow.

Irritation of the vagi, on the contrary, causes, as we have said, considerable acceleration of the respiration; and the quick breathing which we observe in pneumonia is probably due to the irritation of the pulmonary branches of the vagus which the inflammation produces. It can hardly be caused by the venous condition of the blood alone, nor yet by increased temperature; for the blood may be very much more venous in bad bronchitis, and the temperature higher in fever, without the respiration becoming anything like so rapid as in a case of pneumonia. But, although I thus speak of the vagus as an inspiratory or

and expiratory fibres, although the former predominate. (Hering and Breuer, *Wiener Acad. Sitzungs-ber. Math.-Naturwiss. Cl.* vol. lvii, Abt. 2, page 672.) The inspiratory fibres are excited by collapse, and the expiratory fibres by distension, of the lung. Thus, these nerves form a sort of regulating mechanism for the respiratory movements. As soon as a deep inspiration is taken, the distension of the lungs excites the expiratory fibres, and leads to the consequent expulsion of the air; as soon as expiration takes place, the collapse of the lungs excites the inspiratory fibres, and thus leads to renewed inspiration.

As the effect of irritating other nerves as well as the vagus is not always alike (Bert, *Leçons sur la Respiration*, page 490), it is probable that the laryngeal, nasal, and cutaneous nerves, may also contain both inspiratory and expiratory fibres. It has already been mentioned, that the accelerating fibres of the vagus in the lungs are probably irritated in pneumonia, but in bronchitis the expiratory ones are chiefly irritated, and give rise to the expiratory efforts in coughing, which serve to expel any irritating substance in the bronchi. When these fibres are exhausted, or the respiratory centre is feeble or unresponsive, the mucus will remain, and consequently strychnia suggests itself as an auxiliary in such cases. If the irritation depend on something which cannot be removed by coughing, such as miliary tubercle, we employ opium, chloral, etc., which lessen the excitability of the respiratory centre.

Moderate irritation of the superior laryngeal nerve renders the respirations slower but deeper; a stronger irritation prolongs expiration; and a very strong one causes the respiration to stop entirely in the state of expiration (Rosenthal, *Athembewegungen*, p. 244) until the increasing venosity of the blood greatly stimulates the respiratory centre, and causes respiration again to commence.

Irritation of the inferior laryngeal nerve (Burkart, *Pflüger's Arch.*, vol. i, p. 107), and of the supramaxillary (Kratschmer, *Sitzungs-ber. der Wien. Acad., Math.-Nat. Cl.* 1870, vol. lxii, Abt. 2, p. 24), and nasal branches of the fifth nerve, acts in a similar way to irritation of the superior laryngeal nerve, as well as irritation of the cutaneous nerves generally, and especially of those of the face and chest. (Schiff, *Compt. rend.*, 1861.)

We have then to find out whether the alteration in respiration produced by any drug is due to its action on the respiratory centre, or on some of the nerves which influence it; and the following table may help us to do so more readily, by showing at a glance the chief ways in which the respirations may be accelerated or retarded.

The respiratory movements may be quickened by	Excitement of nerves.	Increased irritation of the vagus.
	Greater excitement of resp. centre.	By action of voluntary centre. Increased temperature of blood. Increased venosity of blood. Action of drugs.
The respiratory movements may be rendered slow by	Diminished excitement of respiratory centre.	Diminished venosity of blood. Action of drugs.
	Nervous influences	Slight irritation of cutaneous nerves. Action of voluntary centre. Paralysis of vagi. Irritation of superior laryngeal nerves. Irritation of inferior laryngeal nerves. Irritation of nasal nerves.

If the drug to be experimented on be injected subcutaneously or into the veins, the actions on the respiratory centre and on the vagi are the chief points which require attention; but if we are experimenting with a vapour, its local action on the nasal, laryngeal, and possibly, also, on the pharyngeal nerves (Brown-Séquard, *Archives of Scientific and Practical Medicine*, p. 94) must be carefully attended to, as it may greatly modify its general action on the respiratory centres. Thus Kratschmer has found (*op. cit.*) that tobacco-smoke inhaled by a rabbit through its nostrils, or blown upwards into the nasal cavity from an aperture in the trachea, will cause arrest of breathing in a state of expiration from the irritating effect of the vapour on the nasal branches of the fifth, while it has no such effect when blown into the lungs. Ammonia, when inhaled, also arrests the respiratory movements in the same way; but Knoll (*Sitzungs-ber. der Wien. Acad.*, vol. lxviii, Abt. 3, p. 255) has observed that, if it be blown into the lungs, while the nostrils are carefully protected from its influence, it causes accelerated and shallow breathing, alternating with slow and deep respirations, and occasional stoppages in the position of expiration, obviously from its action on the different fibres of the vagi. When injected into the blood, it causes, according to Funke (*Pflüger's Archiv*, vol. ix, p. 436) various alterations in the respiration, which are not easy to analyse, but it

accelerating nerve alone, I do this only for the sake of simplicity, as this is its chief function. It really contains, however, both inspiratory

certainly seems to excite the respiratory centre; and the use of carbonate of ammonia in bronchitis has long been familiar to the medical profession.

The movements of respiration are not only more easily counted than in any other way, but their depth, and the relation of inspiration to expiration, best noted by causing them to register themselves on a revolving cylinder. Various means of doing this have been suggested by different authors. One of the simplest consists of a needle pushed into the diaphragm, and connected by a thread with one of Marey's levers (see Fig. 2). Marey's pneumograph consists of a cylin-

Fig. 2.—Method of registering respiration. A is the lever of Marey's registering apparatus; B is a hollow drum, with open tube below, and covered at the top with a piece of thin caoutchouc, on which rests a tin plate connected with the lever A. When the air is blown into B, the caoutchouc is lifted, and the lever rises. When air is drawn out, the caoutchouc sinks, and the lever falls. The tube of B may be connected by India-rubber tubing with the respiratory passages in several ways. C is a Tube, open at one end and connected at the other with a cannula, (D), which is placed in the trachea of the animal and brought into communication by its upright limb with B. Instead of D, an India-rubber catheter may be placed in the animal's nostril. E is a caoutchouc-bag, which is tied over the animal's muzzle and used instead of the tracheal cannula. F is a large vessel, from which two tubes (G and H) proceed. G is connected with the lever A, and H with the respiratory passages of the animal. I is a needle, which is simply connected with the lever by a thread: when pushed into the diaphragm, it registers the respirations.

der of soft India-rubber, enclosing a spiral spring, whose extremities are connected with two pieces of metal which form the ends of the cylinder. A band is passed round the thorax of the animal, and attached to the ends of the cylinder. The interior of the cylinder is brought into communication with one of Marey's levers: and as each respiratory movement draws the ends of the cylinders wider apart, or allows them to approach, the air is rarefied or compressed, and a corresponding movement is transmitted to the lever. Bert has modified this, and made it more sensitive by making the cylinder itself of metal, and its ends of India-rubber. Another method—one more ordinarily employed—is to introduce one limb of a T-tube into the nostril or trachea of an animal, or to connect it with a tracheal cannula. The respired air passes through the other end, and the third limb is connected with one of Marey's levers.

IS QUICKENING OF RESPIRATION DUE TO IRRITATION OF THE VAGI?—When the respiratory movements become quickened by the injection of a drug into the circulation, the first cause to which it may be due, mentioned in the preceding table, is irritation of the ends of the vagus in the lung. In order to discover whether this be the cause or not, the vagi must first be divided and the drug injected. If it act only on the ends of the vagus, the respiration which was quickened by injection when the vagi were intact, will not be quickened by it when these nerves are divided.

IS THE QUICKENING DUE TO EXCITEMENT OF THE VOLUNTARY NERVOUS CENTRES?—This cause of quickening is eliminated by narcotising the animal with opium or chloral, or by removing the cerebrum. For the method of doing this, see Sanderson, *Handbook for the Physiological Laboratory*, page 295.

IS IT DUE TO INCREASED TEMPERATURE?—If the temperature of the animal have risen above the normal—the fact can readily be ascertained by the thermometer—it may then be reduced by the application of cold water or ice, or by a stream of cold air directed on the surface of the skin. Unless the cooling be effected very gradually, these applications cause reflex disturbance of the respiratory movements through the cutaneous nerves.

IS IT DUE TO INCREASED VENOSITY OF THE BLOOD?—The drug

may produce this by its action on the blood: and this is to be determined by the means already described. Generally we let a little blood issue from an artery; and if its colour be of normal brightness, we conclude that the gases it contains are also normal.

But external respiration may be arrested or diminished, the blood rendered venous, the respiratory movements consequently increased, and dyspnoea and asphyxia produced by preventing the blood from reaching the air, as well as by preventing the air from reaching the blood. The blood may be prevented from coming into relation with the air: (a) By stoppage of the heart; (b) By embolism of the pulmonary artery; (c) By contraction of the capillaries of the lung.

(a) **BY STOPPAGE OF THE HEART.**—When respiration is suddenly impeded in any of these ways, the breathing becomes panting; and when it is suddenly stopped altogether, asphyxial convulsions occur. When the jugular vein is chosen for the introduction of drugs into the circulation, they come very quickly and without much previous dilution with blood into contact with the heart and pulmonary vessels, and thus affect them more strongly than they would do if injected subcutaneously, or into one of the veins of the extremities. When a large dose of quinine is thus injected, the heart may be stopped at once, and convulsions ensue. Any alteration of the heart's action produced by a drug is easily noted by means of a needle fixed in the ventricle.

(b) **BY EMBOLISM OF THE PULMONARY ARTERY.**—This cause of interrupted respiration may easily lead an inexperienced observer to very erroneous conclusions regarding the action of a drug. Supposing him to inject an unfiltered solution of some extract into the jugular vein, he may find the respiration almost immediately afterwards become panting; the eyes start from their orbits, the limbs become convulsed, the head drawn back, and after one or two quivering contractions, life becomes extinct. He at once concludes that the substance he has injected is one of extreme activity, whereas it may be really quite inert; the violent symptoms which followed its injection being due to the extract being imperfectly dissolved, and the suspended particles producing emboli in the pulmonary vessels.

In some experiments which I made on condurango, I was at first misled by this circumstance, and believed that the drug had a tetanising action, like that of strychnia, as convulsions came on immediately after injecting a solution of the extract into the jugular vein. The same mistake has probably been made by Giannuzzi,* who attributes a convulsive action to the drug. By injecting the solution into the peritoneal cavity, however, I found that it had no action whatever even when used in large quantities, while a solution of strychnia applied in the same manner would have acted nearly as strongly as when injected into a vein.

(c) **BY CONTRACTION OF THE PULMONARY CAPILLARIES.**—When contraction of the pulmonary capillaries is produced by a drug injected into the veins, the venous blood is hindered from reaching the left side of the heart, and the left ventricle and arterial system become empty, and the arterial pressure sinks while the right ventricle and venous system become swollen and turgid. The alteration of the blood-pressure in the arterial and venous systems may be measured by manometers connected with them; but while the arterial fall in the pressure is easily observed, there is considerable difficulty in measuring that in the veins, due to the rapid formation of coagula in the tube which is pushed down the jugular vein into the vena cava.

Another method is, to open the thorax and note the colour of the lungs and the comparative fullness of the right and left sides of the heart, and of the venous trunks, before and after injection of the drug. The animal is first narcotised, and a cannula placed in the trachea. The skin and cellular tissue are then divided along the middle of the sternum and reflected on each side. The muscles are then divided along the line of the costal cartilages, and artificial respiration is begun. The abdominal muscles are then separated from their attachment to the sternum and costal cartilages; the latter are cut through, except the first, which is left untouched in order to avoid wounding the internal mammary artery, and the sternum is bent upwards and retained in its position by a hook. In the rabbit, it is generally unnecessary to tie any vessels, as the bleeding stops quickly of itself; but if any one should bleed much, it ought to be laid hold of and ligatured. Artificial respiration being carefully and regularly kept up by means of a metronome, the colour of the lungs, the size of each ventricle, and the number of cardiac pulsations is observed, the drug injected, and the observation repeated. The pulsations must be counted, because slowness of the heart's action, by affording time for the accumulation of venous blood in the right ventricle, would cause it to become distended, although there were no obstruction to the pulmonary circula-

* Giannuzzi and Bufalini, *Ricerche sperimentali sul Circolo di Fustione*, in *Annali di Medicina e Chirurgia*, pp. 71-86; abstracted in the *Centralblatt für die Med. Wiss.*, 1873, p. 824.

tion. When the drug to be experimented on is not a solution but a vapour, it must be passed into the lungs by the method already described (BRITISH MEDICAL JOURNAL, May 20th, 1871).

In this way, I have found that muscarin causes contraction of the pulmonary vessels, and produces dyspnoea (see BRITISH MEDICAL JOURNAL, November 14th, 1874), although the heart continues to beat, and artificial respiration is vigorously kept up. The lungs become pale, the right side of the heart swells up, and the left side and arteries become empty, as represented diagrammatically in Fig. 4.

Fig. 3.

Fig. 4.

Fig. 3.—Diagram representing the normal condition of the circulation. Both the veins and arteries are moderately full; the two sides of the heart are of much the same size, and the circulation through the lungs is free.

Fig. 4.—Diagram representing the condition of the circulation after the administration of muscarine. The veins are distended, the arteries empty; the right side of the heart is much enlarged, the left side collapsed, and the circulation through the lungs almost entirely arrested.

The vapour of chloroform blown into the lungs causes a similar appearance, but it arrests the cardiac pulsations more or less completely at the same time.

The action of drugs on the pulmonary capillaries in the frog may be observed directly by means of the microscope. A frog is curarised, and a glass cannula, to which a short piece of India-rubber tubing is attached, is tied into its larynx. An incision is then made into the side of the frog a little below the arm, care being taken not to injure the lung in dividing the thoracic wall; and the lungs being inflated through the cannula, one of them protrudes through the opening. The piece of India-rubber at the end of the cannula must then be clamped, so as to prevent the air from escaping and the lung from collapsing (Fig. 5).

Fig. 5.—Form of tube for insertion into the larynx of the frog. It is made by drawing out a piece of tubing to the size marked *a*, heating the end and pressing it against a piece of metal, so that it assumes the shape *b*. *c* is a piece of India-rubber tubing, which must be closed, either by a ligature, as shown in the drawing, or, what is still better, by a clip, so as to prevent the escape of air from the lung.

The whole frog is then placed on a glass plate, which is fixed with a clip to the stage of the microscope. The lung is brought under the objective, and supported, if necessary, by a cork ring fixed to the glass plate with sealing wax. Any changes in the calibre of the pulmonary vessels are then readily observed by means of a micrometer placed in the eye-piece.

Four years ago, I attempted to ascertain by this method the effect of sudden changes from heat to cold on the lungs; and I have found that, if a stream of warm moist air be first directed on the lung, and immediately afterwards a stream of cold moist air, the capillaries sometimes contract as much as one-third of their diameter under the influence of the cold.

Dr. Sharpey informs me that the lungs of the toad, unlike that of the frog, does not collapse even when no obstruction is offered to the escape of air; and therefore, if toads be used, the India-rubber tube and clamp on the cannula are unnecessary.

THE LATE DR. PICKFORD.—At the annual general meeting of the Brighton and Sussex Infirmary for Diseases of the Eye, the following resolution was passed: "That the Governors of this Charity desire to offer to Mrs. Pickford their sincere expression of condolence in the loss of her late husband, Dr. J. H. Pickford, to whose exertions the Charity mainly owes its foundation, and who, during a period of more than forty years, exerted his best interest in its behalf."

REMARKS ON THE LOCAL USE OF LIQUOR FERRI PERCHLORIDI IN CANCEROUS ULCERATIONS OF THE UTERUS.

By CHARLES J. GIBB, M.D.,

Consulting Surgeon to the Newcastle-on-Tyne Infirmary.

CANCEROUS diseases of the uterus have generally progressed so far before they come under professional observation, as to pass as incurable from one medical man to another, and it thus happens that I see a large number in my consulting-rooms. It is rare to find the disease so superficial and purely epithelial in character, or, if interstitial, so confined to the mouth and neck of the uterus, that the diagnosis can be made with such certainty as to justify the surgeon in excising it; and, in the advanced stages, the foul discharges make the patient so loathsome, that, in spite of the keenest feelings of pity, the surgeon is inclined to view the case as utterly hopeless, and to leave all manual treatment to the nurse. When we remember how much relief can be given to the worst symptoms of the most incurable cases of external cancer by operation, or by other measures calculated to remove fungoid or sloughing surfaces or masses of the disease; how pain can thus be relieved; bleedings prevented; foul discharge moderated or made less disgusting in character,—it is not surprising that surgeons should strive to give similar relief to the worst cases of cancer of the womb, and be more or less successful in their efforts. From time to time, I have tried the various local applications I have seen recommended; have made use of many caustics; have been taught by painful experience that caustic potash, or caustic potash and lime, are unmanageable, and too dangerous to the surrounding parts to be used with the freedom requisite to be of service; that the actual cautery is too fear-inspiring; that nitric acid or acid nitrate of mercury (which had to be used with great care) are inefficient; and that lunar caustic and powders or points of zinc or alum are useless as caustics.

About two years ago, I had occasion to dilate the uterus in a very obstinate case of menorrhagia proceeding from large vascular granulations in the cavity of the enlarged organ. The strongest pharmacopœial solution of the perchloride of iron (being in fact iron dissolved in pure acid) was injected into the open uterine cavity, and a piece of sponge soaked in the solution left there for twenty-four hours. This treatment was perfectly successful, and I viewed with surprise the efficient way in which the soft and vascular growths were destroyed, while the normal structures of the uterus and vagina were but little inconvenienced, and certainly not in the least eroded. Since that time, I have been accustomed to use this solution in many cases of cancer of the uterus; and, having promised our secretary to read a few notes at this meeting regarding its usefulness in my hands, I jotted down the histories of the following cases, being the cases of cancer in which I used it in my consulting-rooms during the week succeeding the day I made that promise.

CASE I.—Mrs. B., aged 36, a shopkeeper, married five years, without children, was a strong powerful woman until fourteen months ago, when she was seized with menorrhagia, followed by the foul sanious discharges and other symptoms of cancerous ulceration. She came to my office six weeks ago, anæmic to the last degree, from almost constant hæmorrhage and putrid discharge. On examination, the mouth and neck of the uterus were found destroyed, and their place occupied by a large, deep, sloughing, cancerous sore. The body of the uterus felt greatly enlarged, and as hard as a cricket-ball, whilst the vagina was quite free from disease. Profuse hæmorrhage attended the examination. The sore was filled with cotton-wool soaked in the solution of the perchloride, and the vagina stuffed with tow. She came from a distance by rail, and was ordered to remove with her fingers, or allow the lady who accompanied her to withdraw, the stuffing of tow next morning, and trust to the injections of zinc and alum to wash away the cotton-wool; and appropriate blood-making and aperient medicines were prescribed. On her second visit, she expressed herself as much stronger, very little bleeding having taken place during the week. The application of the perchloride was repeated; and I did not see her for the next ten days, in consequence of a severe pain compelling her to remain in bed. The sore was much healthier in appearance; there had been very little bleeding, and the discharge had become scanty and semi-purulent in appearance, without any of the old putrid smell. She was, however, very feeble, and made the journey with great difficulty. Instead of placing the cotton-wool soaked in the perchloride over the sore, I elevated her breech, half filled the vagina with the solution for a couple of minutes, then sucked it up with a syringe and left a plug of tow in the vagina, to be removed next day. The improvement was

marked on her fourth visit, and on this, her sixth, I found there had been a little bleeding once during the week, whilst forcing away a very costive motion. The ulcer was perceptibly smaller, and free from slough, the circumference of the vagina having contracted considerably around it. A small quantity of oil-like pus lay in the vagina; but the examination still caused the ulcer to bleed slightly. The ulcer was again bathed with the strong perchloride, and she returned home, expressing herself as twice as strong as when she first called upon me, and very much relieved from the local misery.

CASE II.—Mrs. R., aged 36, an innkeeper, with several children, the last 7 years old, commenced to have menorrhagia, and the ordinary symptoms of cancer of the womb, nearly a year ago. She began to attend my offices four months ago, and was found to have a large, soft, bleeding epithelioma, covering the swollen and apparently destroyed vaginal parts of the uterus, and extending along the front wall of the vagina to within an inch and a half of the orifice of the urethra. She came in a cab, and her linen was drenched with blood. She was exceedingly anæmic, with daily hæmorrhage, and was evidently in the last stage of the disease, the sore bleeding on the least examination. A large piece of cotton-wool, soaked in the perchloride, was placed over the diseased part, and the vagina was stuffed with tow. On her second visit, a week afterwards, the hæmorrhage had almost ceased; the sanious putrid discharge was much lessened, and, though there was little change to be seen in the appearance of the sore, the finger felt it to be less fungoid and putrescent in consistence, and less blood followed the examination. I may here remark, that the bleeding fungoid sores were so extensive as to make it utterly impossible to use any speculum, and the oiled finger of myself and assistant had to be used to open the vagina and make the necessary examination and applications. The same examination was made weekly during the nine successive visits, by which time she had regained much of her lost strength, walking a considerable distance to my rooms, and experiencing but little pain or inconvenience, except in passing urine and feces. The hæmorrhage had ceased after the third application; the foul sanious discharge had given place to a scanty oil-like purulent matter without smell; the fungoid vaginal sore was healed, or rather, converted into a thick nodulated, gristly, cicatricial substance, covered with a thin smooth membrane, whilst the deepest part, that corresponding to the uterus, alone presented a chink-like ulcerated surface. It was difficult to see or reach the deepest part, on account of the remarkable contraction that had taken place in the calibre of the vagina, which, from being very capacious and soft, admitting several fingers, had become changed to a rigid tube, that would scarcely allow more than one finger to pass along the upper part of the canal. At this period, some of the children became ill of fever, and she did not visit me for six weeks, having gone through much fatigue in nursing them. On again examining her this week, on her return, I found she was again suffering from a recurrence of the hæmorrhage, consequent, as she asserted, upon the menstrual flow; and I found also that the disease had again opened out the deepest part of the cicatrix, and formed an irregular foul ulcer nearly the size of a crown-piece. The front part of the cicatrix remained in much the same condition. I covered the sore with wool soaked in the perchloride, and warned her against such negligent attendance in future.

CASE III.—Mrs. B., aged 46, a stout healthy-looking lady from the country, the mother of several children, called upon me about a year ago, having slight discharge and bleedings in the intervals between the monthly periods, as well as excessive monthly flow. Her other symptoms were so slight, that her husband, who was also a patient, had difficulty in persuading her to see me. The mouth and neck of the uterus were found to be red and raw-looking, bleeding on the slightest touch, also hard and considerably enlarged, and there was an ulcerated crack at the orifice of the organ. She attended my rooms once a week for about two months. Lunar caustic was applied at first; but, as it produced little change, the perchloride was used a few times with such good effect, that, considering herself quite well, she did not return to see me until to-day, when, she tells me, the bleedings have again returned lately, and she feels a heavy uncomfortable weight in the uterine region. On examination, the whole organ is found greatly enlarged and very hard, being evidently infiltrated with scirrhous disease. The old ulcer is again open, bleeds freely on examination, and there is considerable discharge. The perchloride has been applied.

CASE IV.—Mrs. F., aged 69, from the sea-coast, consulted me about eight years ago for a discharge, occasional menorrhagia, and the uncomfortable bearing-down and other symptoms indicative of uterine mischief. The uterus was found atrophied, and the os and neck almost destroyed by a chronic canceroid ulcer, in appearance like lupus; the whole case reminding me strongly of a similar condition of the breast which I have often seen in old people to continue in a chronic state for years. Potassa fusa and other caustics and injections were used for

more than a year, the result being the total destruction of the vaginal part of the uterus and the formation of a deep sulcus there, which, after remaining healed for some months, again opened out, and has ever since compelled her to attend my rooms two or three times a year for a month or two together. A slight bloody discharge is the only symptom that now tells her the cicatrix has given way, and of this discharge she has the greatest dread. Lunar caustic or nitric acid, with the use of injections, were generally successful after a time in healing the sore, or rather, crack in the cicatrix. I am now accustomed, however, to fill the wound with a small piece of wool dipped in the perchloride, and retaining it there for the first day by a plug of tow in the vagina; find it frequently, in spite of the use of injections, to stick in the place until next visit, a week afterwards, when I remove it. I find the perchloride to be by far the most effectual means of healing the scar when it cracks and bleeds; and on this occasion I made the usual application.

In reviewing the above cases, I have to remark that, since the first case was committed to paper, the patient has visited me twice, and on each occasion has reported large losses of blood, although, on examination, the sore looks clean, and the discharge remains a thick brownish pus quite devoid of smell. What remains of the uterus is infiltrated with cancer; and, although the treatment has greatly relieved the most distressing symptoms, it is evident that a fatal termination cannot long be delayed. Indeed, I have seen that, where the form of cancer is hard, and embraces the whole of the uterus, the destruction of the enlarged organ often takes place by a rapid disintegration attended with alarming gushes of blood, and all that can be done only lengthens the downward path, and makes it less foul and painful. It is different with that class of cases of which the second is a good example. Here there was as pure an epithelioma as is met with in the uterus, spreading over the adjoining surfaces of the vagina, and not infiltrating or running deeply into their structures, but throwing out surfaceward exuberant vascular fungoid granulations, quickly renewed as the older parts sloughed away. Into this soft albuminoid structure the acid solution of iron sinks, destroys, and disinfects; and, strong as it is, it only hardens and tans, but does not in the least destroy the healthy mucous membrane of the vagina. A few applications of the cotton-wool soaked in the solution suffice to clear away the greater part of the diseased growth. Reparative efforts are then made by the comparatively healthy structures underneath, and the further applications appear to hasten cicatrization, as well as to eradicate the remains of the disease. In one case very similar to the second, the lady has now been quite well for some months, and the resulting cicatrix, when she ceased to attend upon me, had so narrowed the upper third of the vagina, that the finger could not pass along it, and was so thick, and hard, and tubercular, that I could not resist coming to the conclusion, that, in the process of cure, a large amount of albuminoid matter had exuded into, and become solidified in, the structures surrounding the disease. Whether the thickening and solidification of the cicatrix and immediately adjoining parts is what naturally takes place in this region when epithelial cancer is destroyed by other caustics, I have no experience to know; possibly it may partially result from the action of the solution left for so long a time on the highly vascular structures supporting the diseased growth—structures that have been so long accustomed to throw into the diseased mass the large supply of albuminoid food necessary for its support. In another case of apparent cure, where the epithelial disease was confined to the uterine structure, I did not observe this condition of the cicatrix; and it may be that the presence of so much connective tissue in the vaginal wall is the cause as well as the seat of this peculiar formation, reminding one of a bad case of keloid growth in the skin, or the hard irregular cicatrix of a bad burn. The course of cancer in the womb is sometimes so rapid, from the quick disorganisation and sloughing of the uterus, and the sufferings of the patient so great, that it is impossible, in a dispensary practice like mine, to see such cases as often as necessary, and to follow them out satisfactorily, or to persuade a sensitive woman to have repeated applications of an agent which does not give immediate or permanent relief. In such cases, indeed, no remedies can be of much avail. It is when the disease is purely epithelial, and chronic, and rodent in character, and confined to the surface, that the treatment I have described does most good, and, as I have said, appears to cure even bad cases. The application of the perchloride rarely causes pain. On four or five occasions, a patient, on returning home, has been confined to bed for a few days, and, in one of the successful cases, for upwards of a fortnight, in consequence of a severe colicky pain in the region of the uterus, lower abdomen, and back. I am inclined to think that the wool had been oversaturated in the perchloride in such cases, as it has occasionally happened that the solution has flowed from the vagina over the vulva after the patient has left my offices, and those

parts been blistered and painfully excoriated as a consequence. On this account, I am now very careful to wash away with a syringe all discharges from the surface of the cancer, and to raise the breech of the patient to prevent any overflow of the solution over the vulva, and, after applying the perchloride, to suck up with a sponge from out of the bottom of the vagina any superabundant solution which a slight pressure on the saturated wool over the sore may cause to flow out; after that, to retain the wool in its place by a loose plug of tow in the vagina; and, lastly, to dry and oil the vulva before the patient rises from the couch.

I have always used the strongest pharmacopœial solution undiluted, as I have only used it to secure a caustic action. At first, I applied it on a piece of sponge or lint; but finally found cotton-wool to answer best, as it sucks up any quantity that may be required, parts with it easily, and can be moulded into any form, so as to fill a cavity or cover over and adhere to any growth. It has happened occasionally that I have found the cotton-wool still adherent over the sore a week or more after its application, and, when removed, it is always a black or chocolate-coloured mass, frequently quite solid, from the quantity of blood or albuminous matter absorbed in its meshes and clotted therein; indeed, one patient gravely told me she had passed a solid brown egg a few days after one of her visits. No doubt it was the hardened wool, although she declared she had cleared out the vagina the day after her visit.

I have kept no record of all the cases I have treated with the perchloride; but, as I have generally had six or eight under treatment at one time, I must have used it in twenty or thirty cases; and its beneficial influence has been so marked, that I would strongly recommend its trial in suitable cases. (*Brit med. Journal*)

CASE OF LARYNGITIS: TRACHEOTOMY: RECOVERY.

By SURGEON-MAJOR J. H. PORTER, Assistant Professor of Military Surgery, Army Medical School, Netley.

IN this case, an acute attack supervened on the disease in a chronic form.

Gunner T. W., Royal Artillery, aged 30, of thirteen years' service, was invalided from India in February, 1874, after a residence there of seven years, on account of extensive syphilitic disease, affecting the bones of the left foot. When he arrived at Netley on April 23rd, 1874, he was suffering from hoarseness of voice and irritative cough, which had first attacked him on board ship, immediately after entering the Mediterranean. Inhalation of the vapour of turpentine and creasote was ordered, while iodide of potassium was given internally; and under these remedies the laryngeal symptoms had so nearly disappeared, that the usual arrangements were made for him to leave the hospital on the 8th of July. On the 3rd of the month, however, the laryngeal symptoms suddenly became aggravated, his voice became weak and hoarse, and he was troubled by cough of a croupy character. The treatment which had relieved him before had now no salutary effect, but appeared rather to aggravate his symptoms. Minute doses of antimony were then administered, the temperature of the ward was kept high, and under these circumstances the patient experienced relief, and appeared to be progressing satisfactorily, when, at 2 P.M. on the 7th of July, he became much worse. His countenance became livid, his skin was bathed in cold perspiration, and he suffered greatly from hoarse cough, accompanied by bloody sputa, and a sense of impending suffocation. He complained of great pain on the right side of the larynx, which was swollen. The pharynx was greatly congested, and the epiglottis could be felt enlarged and thickened. The highly sensitive condition of the parts prevented the use of the laryngoscope. He obtained comparative relief at intervals, but at 4 P.M. his symptoms assumed such a threatening character, the patient being almost asphyxiated, that it was decided to open the trachea.

The condition of the larynx precluded direct surgical interference so far as it was concerned. Chloroform having been administered, the patient was placed in position for the performance of tracheotomy. The knife had already touched the upper rings of the trachea, when the patient ceased to breathe, became quite black, and was apparently dead. Without delay the scalpel was plunged into the trachea, and, with considerable difficulty, a tube was introduced. Artificial respiration was then adopted by means of Silvester's method, and in about ten minutes animation was restored. In half an hour he was breathing easily, and expressed himself in writing grateful for the relief he had obtained.

Under most careful nursing by the sisters of the hospital, and the administration of iodide of potassium in large doses, he steadily improved. The tube was removed on July 16th, on the ninth day after the operation, to ascertain if he could breathe without it; but in less than five minutes breathing became so distressed that it had to be at once replaced. The tube was taken out on several occasions between the above-mentioned date and July 24th, but it was found that he could not remain long without it. On and after the 24th, however, the forty-fourth day after the operation, it was not found necessary to replace the tube, as his breathing continued quiet and easy without it. On September 8th, the wound had completely healed, and his voice had nearly recovered its former strength, and he was discharged from hospital.

There are two points in cases of laryngitis which frequently cause the surgeon much anxiety. The first is, to decide on the proper moment for surgical operation, when it has been determined to operate; as after each spasm there is temporary relief, and this may induce the surgeon to hope that the threatening symptoms of the disease have subsided, so that the need for the operation has passed away. Under these circumstances, the operation may be postponed till perhaps it is too late. The safest plan is no doubt to operate early. The second point is, to determine the proper time for the removal of the tube. This can only be settled by attention to the feelings of the patient, and observation of his power to respire without it.

ON THE MANAGEMENT OF LABOUR AS FAR AS REGARDS THE PREVENTION OF HÆMORRHAGE AND SEPTICÆMIA.*

By I. HARRINSON, F.R.C.S.,
Fellow of the Obstetrical Society.

IT was well remarked by a speaker in one of the great discussions which took place at a metropolitan Society, that it was needful to have a clear and distinct understanding of what they were talking about. The remark holds good in a debate on obstetrics, and fully applies to our doings in its practice. It is a mistake, I contend, in the practice of obstetrics, to look upon it as a series of regulation-formule, to be treated after a set and recognised fashion, rather than as a natural process, modified as it may be, as it must be, and as it is, by varied accidental complications. We must act on general principles, founded on the anatomy and physiology of the parts concerned.

Up to the time of the establishment of the true action of the spinal marrow and of the reflex system by Dr. Marshall Hall, of their application to obstetrics by the late Dr. Tyler Smith, and of the splendid dissections and demonstrations of the uterine supply of nerves by Dr. Robert Lee, many of the phenomena of parturition were inexplicable, or their explanation was contradictory. The observations about to be made are founded on their teachings.

The uterus is a muscle of the involuntary class, of a non-striated character, the fibres of which, in the pains of labour, after remaining in a state of contraction for a brief period, relax; as is invariably the case in non-striated muscle, it being incapable of sustained effort, says Dr. Leishman. It has a peristaltic action of its own. It is connected with all the nerves from the medulla oblongata to the sacrum—cerebral, spinal, and sympathetic. The uterine group includes the nerves of the ovaria, Fallopian tubes, uterus, vagina, and the external parts of generation. Hence its sympathies and synergies are innumerable; they include affections of the head, breasts, stomach, suprarenal capsules, bladder, rectum, os and cervix uteri, and of the external parts; and may be direct or reflex—mainly reflex. "Thus, in parturition, the uterus may be excited in a reflex form by irritation of the mammary incident excitator nerves, the pubic and abdominal branches of the intercostals, the rectal, the gastric division of the pneumogastric, the ovarian nerves, and also by the nerves of the vagina and the os and cervix uteri. These act through the medium of the spinal marrow, the great organ of physical motion." (Dr. Tyler Smith).

It will not be contended, I take it for granted, that the uterus is an isolated organ, having no nervous connections or supply. If any doubt—and there are some who do—let him look at these beautiful plates of the dissections of Dr. Robert Lee. It will be admitted, also, that the vessels and nerves enlarge *pari passu* with the growth of the uterus during pregnancy.

An organ so endowed must have extensive susceptibilities, and be the recipient of a wide range of reflex impressions. Let us take an

* Read before the Reading Pathological Society.

example or two. A nurse upset a well furnished clothes-horse on to the fire. The consequent blaze excited an immediate convulsion in a lady in the last pangs of labour. A lady was confined after an easy labour; but the uterus contracted and relaxed alternately for three hours afterwards. The hemorrhage was alarming. At length, violent vomiting occurred; the stomach was unloaded of a basinful of boiled mutton and turnips—the dietetic ingestment of the previous evening; and then contraction firmly took place.

The obstinate vomiting of pregnancy is, I believe, mostly dependent either on disease of the suprarenal capsules or on ulceration of the os and cervix uteri. The reflex action of an irritated nipple, a loaded rectum, a distended bladder, a vaginal examination, a hand on the sacrum, are familiar to all. Ulceration of the os and cervix uteri, the irritation caused by the various mechanical appliances to and in the uterus, the process of periodic and final uterine involution, etc., elicit a multitude of nervous expressions in various parts of the body as yet dimly recognised as regards their true source, and entirely misunderstood as regards any other.

Let us now clinically sketch a case of first labour. It may be presumed that the woman is married, of a proper age, her surroundings favourable, and that all her bodily functions are in good working order. We will grant that she has arrived at the full term of utero-gestation. Pains begin, at first slight, and then more severe. I need not hazard any conjecture on the causes which determine the commencement of pains at the completion of the term of utero-gestation: it is enough in this place to say that so it is appointed. It is, however, important to observe, and is never to be forgotten, that each pain is followed by an interval of rest. In spite of flattering first impressions, experience now dictates the negation that no adverse agencies, direct or indirect, are at work; that there is nothing in mind, body, or estate, operating injuriously—nothing inimical to uninterrupted progress, nothing likely to disturb the even course and finish of the coming trial. Have seduction, desertion, depression, fatalism, etc., any occupation to lower, preoccupy, spoil, divert, harass, the unfettered play of the nervous power, and cripple its undivided exercise? Let no stranger intrude; let the officiousness of friends be curtailed; and, above all, let the practitioner take care that he himself is not the bearer of any pestiferous agency.

All these preliminaries being duly considered and disposed of, let us fancy that in due time the head has been brought to, or nearly to, the perineum, and there remains. Time is precious; thoughts of pressing engagements intrude themselves; the loss of a night's rest is imminent. The occasion is a tempting one to try something to rouse these tire-some efforts into something like a decent state of activity and progress. Ergot has an abiding place in most men's minds, and usually turns up uppermost. What indication could be clearer? A few good pains would do all that is needed. Ergot produces pains, and therefore ergot is just the thing required. Ergot of course is given. Probably no action is induced; possibly a violent, long-continuous one; but no further advance is effected. Let it not be forgotten that, for successful efforts, there must be a general consensus of conditions. Who has not observed how the patient, by a wondrous intuition, anticipates the coming struggle? Who so unobservant as not to know when that is approaching by the flow of lubricating fluid? In short, the woman instinctively prepares herself by position, by inspiration, by profound rest, and by silence.

How does the action of ergot accord with these conditions? What is its action? "The contractions and pains caused by ergot", says Pereira, "are distinguished from those of natural labour by their continuance. Scarcely an interval can be perceived between them, but a sensation is experienced of one continued forcing effort."

Nature beneficently ordains that the uterus shall fulfil its office by alternate pain and pause. Ergot obliterates the normal rhythm. Nature says a congeries of conditions is essential for the final effort. Ergot violates them all, invites irregular contraction and its consequences, and delivers the patient an easy prey to the immediate and ulterior probabilities of hemorrhage and of septicæmia. In addition, let it not be forgotten that in primiparæ the parturient passage is unstretched, and not yet to the manner used.

In primiparæ, ergot may be useful, or rather used, in some cases, to save the time of the attendant, all other things being favourable; and, if it act and succeed, all may be well. It is equally evident, however, that if it succeed, the success will be suspicious; and, if it do not, it must be calamitous.

It may be asked, not unreasonably, by younger members, If ergot should not be used, what may? Tax voluntary and emotional effort. Draw on the rich fund of direct and reflex action. Initiate contractions by a lump of ice in the stomach; by frictions to the abdomen and spine; a stimulating injection into the rectum for one reason, or one of hot

water for another; by a dig at the sacral plexus, or a pull at the perineum, on the access of a pain; by the sudden application of cold, with a bellows if you please, to the sacrum; and by many other means yet to be found out. Try all or some of these; and, after them, the forceps.

We will now suppose that, by a grand effort without ergot, the head is born. There is no need of hurry. There is no necessity to seize it with both hands and drag the body into the world; let it alone. Bearing in mind what has just happened, and how it happened, the right hand must be placed on the bare abdomen of the mother, and gently carried over every available surface of the uterus, and repeated till contraction comes. It comes soon, and by it the shoulders and body are usually expelled.

The child, being now free to kick and cry, should be brought near to the edge of the bed, and the bedclothes put down between the mother and child, so as to cover the mother and expose the child. The hand should then again be carried to the abdomen, and gentle manipulations exercised, till not only angularities, but nodosities and even rugosities, are obliterated, and the uterus has become round and smooth.

The baby can now be attended to, separated, and delivered over to the nurse. This being done, the uterus must again be similarly attended to. After another short interval, the cord should be wound round the forefinger of the left hand; and at the same time the forefinger of the right hand run up the cord to the os uteri, and traction made. If the placenta be ready to come, it will come by a gentle effort. If the insertion of the cord or an edge of the placenta can be felt, then, by a combined action of traction by one finger and hooking with the other, the expulsion of the placenta is nicely assisted. The time occupied is generally under ten minutes. If the combined effort do not succeed, a little more time must be given, the uterus again stimulated, and the trial renewed.

After the placenta has come away, the uterus must again be tested as to its firmness and rotundity, and this twice again repeated, before the patient can be considered safe. In perfect contraction of the uterus is comprehended the safety of the patient, immediate and prospective. Up to this period, it is no part of the attendant's duty to leave the room, much less to adjourn to the dining room, to scatter congratulations all around, and, perhaps, to the health of the new-born stranger. Such customs are more honoured in the breach than in the observance.

This practice, simple as it is, may be managed in a different way by others. Some have the hardihood to affirm that the uterus should be grasped at the moment of the birth of the child, and the placenta forced down *vi et armis* and out by the same pain that expelled the child, or, at the longest, by the next. The practice seems to be founded on a mistake. What occurs when the hand is placed over the uterus? The slightest touch produces an immediate reflex action and a contraction of the uterus; and it is thus by a series of succussions that the crooked uterus is made straight, and the rough places smooth. Thus it is that the placenta is readily brought down. On the contrary, if an untimely contraction be produced by forcible pressure, it follows, that a corresponding relaxation must ensue and danger come.

How does forcing down the placenta by one fell swoop agree either with Nature's method, or with the teachings of reflex physiology? Admitting that the pain which expels the child separates the placenta, surely it is more in accordance with Nature's doings that it should be expelled gradually and by gentle efforts. It is unpractical to suppose that the uterus should pass from extreme distension to extreme contraction without a rebound to the intermediate state of vacuity and of peril. Again, I am not prepared to say what changes precisely occur in the relative circulation of the placenta and the uterus after the birth of the child. It is quite certain that the cord pulsates for a short time afterwards, and that the uterus has at least to adapt itself to its altered contents.

If the waiting plan be adopted, the placenta may be retained for an indefinite time; and then instructions are given, even to women, to introduce the hand and remove it. This direction is given with the greatest coolness, as if it were an easy or a safe thing, particularly for a woman, to introduce the arm into the uterus and rifle it of its contents. Such advice can only be given in utter disregard of the peristaltic action of the uterus itself. Ergot, forcible extension of the placenta, introducing the hand to remove it, these three can only be regarded as practices of misleading efficacy, and as *membra disiecta* of the mechanical school. They must be reserved for cases alone of special exemption. In this counterblast, of course, the triumphs of cautious instrumentalism are not included.

Some practitioners, immediately after the birth of the child, think that their next duty is to separate it; and, whether the child cries or not, proceed to do so. Under the cover of the bedclothes, perchance

The body should for a moment be exposed to cold, or for some other equally cogent or perhaps unknown reason, the separation is mysteriously accomplished. It is better to avoid such subterfugary proceedings, involving as they do the expenditure of critical time and a risk of the mutilation of a penis or a finger; and also if it be wished to prevent that bane of infant well-being, "atelectasis pulmonum".

It may be expected that something should be said about the binder. I have little to say, except in its condemnation, if used for the purpose of restraining uterine hemorrhage. If applied when the uterus is well contracted, it is useless; if when relaxed, it will be injurious by covering over and concealing the source of danger. Its great use is as a surgical appliance in giving support to the relaxed abdominal parietes, securing their equable adaptation to the abdominal contents, and thus facilitating their contraction and timely involution. On this account, it is neither well nor fitting to pull the patient about, when quiet is so essential, to adapt the nicely made bandage. An easily applied slip is that is needful for the first twenty-four hours.

My conviction is that the bandage should be continued for at least a month after each confinement, if we are anxious to preserve the normal relation of the axis of the uterus to that of the pelvis, and so prevent delay and danger at subsequent confinements; or if we desire to avoid the unsightly protrusion of a pendulous belly. Let cases be stripped of the accidents, largely avoidable, which we have been considering, and how many remain to be dealt with? Only those unforeseen and unavoidable cases of peculiar hemorrhage, dependent on idiosyncrasy, examples of which were so well and so courageously related by Mr. Crisp at our last meeting.

In such cases, it is not to be expected that remedies having a reflex operation should be of all avail; more immediate and direct means must be employed, as the hand to the internal surface and the introduction of various substances into the cavity of the uterus. I say introduction, not injection. When, in the induction of premature labour the injection of water alone has proved fatal, I think we should be cautious how we inject fluids which may prove fatal not only in that way, but by reason of their engendering septicæmic sequelæ. Besides, the styptic fluid needs only to be applied to the surface of the uterus, and should not permeate the sinuses.

It will have been seen that principles rather than practice, except in some of its more prominent bearings, have engaged our attention; that the aim has been to inquire how and by what agencies Nature manages the process of parturition, and to insist that she must be acknowledged, not ignored; not forced, not fettered; not supplanted—in her operations; and that physiological relations rather than mechanical expedients should be had recourse to and depended on, and to show that the glory of contingencies consists in their prevention; that the eternal law of labour and of rest should be borne in mind in all our doings, and also that the more violent the action and consequent exhaustion, greater will be the probability of prolonged rest and of undue relaxation; hence the occurrence in the greater degree of hemorrhage, and in the lesser of imperfect contraction and subsequent septicæmia.

It may be objected that such a sketch is visionary and unreal, and that it refers to the occupants of a too happy land, and that in the hurry and bustle of this lower world accidents must needs come, and, therefore, it is folly to ignore, taboo, and discard the well used helps of obstetric necessities. All I contend for is that those helps should be studied from a different point of view; that the act of parturition should be looked on as a natural process, to be gently assisted by natural means, and not by any foreign, and, entirely subversive of, her teachings, and that general principles are applicable and adaptable to every emergency.

Let it be borne in mind that midwifery has not till very lately, and is still not now generally, been studied in this way; that labour has been looked on as a mechanical act, to be completed as soon as commenced, and the sooner the better; that the effects of the nervous relations of the uterus are only just beginning to be perceived; and that in this direction, and from this source, our future remedies are to be sought and are to be found.

I am quite aware it may be said that the standard is placed much too high for such a common and everyday occurrence as that of parturition. Be it so. The object is the alleviation of pain and suffering; to aim higher is impossible; lower would be reprehensible.

My conviction is that, till the science and art of obstetrics are placed on a physiological and not on the prevailing mechanical basis, we shall continue to be the slaves of routine, and our patients the victims of fortuitous complications; and that then, and not till then, will the possibility of hemorrhage be mainly prevented and the chances of septicæmia reduced to a minimum.

RECENT PUERPERAL EPIDEMIC AT COVENTRY.

By M. A. FENTON, M.D.,
Medical Officer of Health for Coventry.

As the epidemic of puerperal fever from which Coventry has just suffered has excited some discussion as to the contagious nature of that disease, I think a short account of the epidemic may prove interesting. It is of importance, as it affords strong evidence in favour of the fever being extremely contagious. The first case occurred in November last. A woman, whose family was suffering from scarlet fever, was attacked by a mild form of the disease. A lying-in charity, which lends out to poor puerperal women bags of the linen requisite for such an occasion, and pays a midwife, and medical man, if required, for the patient, came into play in spreading the complaint. The bag of linen was returned to the matron, who placed it with another in a store. These bags were lent out again early in December, and both the women suffered from fever, one lightly, one very severely. There was no other source of infection. They were both attended by the midwife Ingram. The three following cases attended by Ingram on December 12th and 13th, were attacked with fever the day after delivery: two died on the fifth day, the third survived; but the medical man who was called to treat her carried the infection to the next parturient patient he attended, and this case proved fatal. Ingram's next case also proved fatal. She then (having received the coroner's warning) made arrangements with a medical man that she was to attend as usual, but not to deliver, or make vaginal examinations; she was to send for him when delivery was about to take place. This was done in one instance, the patient doing well; in the next case, the medical man disappointed her, and she delivered the woman herself. The day following, rigors issued in the fever which proved fatal. Ingram was then committed for manslaughter.

In connection with another lying-in charity, three cases of puerperal fever occurred. In the first instance, no apparent source of infection could be discovered; the woman was attacked on the second day, and died on the seventh day after confinement (December 1st). The linen belonging to the charity was returned, and six weeks afterwards was lent out again. The unfortunate woman receiving it was infected and died; and the midwife attending her infected the next case she attended, though not fatally. This midwife has also been prohibited from practice by the coroner. It may be a matter of doubt whether the coroner acted according to law in taking the course which he did; however, with the evidence before him, which I have stated above, I have no doubt it will be admitted that he acted very wisely, and I have to thank him for so doing, for he has stamped out an epidemic which I (as medical officer of health) found myself unable to cope with for want of power to take the steps which he did. The origin of the epidemic appears to me to be rather obscure. I have seen in our late epidemic of scarlet fever a woman who, for the first week after confinement, lay in the room with two malignant and fatal cases of that fever without hurt. Why, then, should the woman in this instance escape when another is infected? May there not be some meteorological conditions rendering the constitution more susceptible at one time than at another? There is another point of interest with regard to the mode of infection, viz., the only woman who escaped Ingram's fatal influence was one whose vagina she had not touched. Is it possible that this is the only channel through which the virus is conveyed?

REMARKABLE CASE OF COMPLICATED PREGNANCY: MISCARRIAGE AT SIX MONTHS.

By FREDERICK C. GRANT FLETCHER, L.R.C.P. Ed., Lindley, Huddersfield.

ON July 18th, I was called to see Mrs. K., aged 34, the mother of six children. I found both the legs and feet cedematous, and somewhat elastic, the œdema apparently of active dropsy. The abdomen was in size between a six and seven months' pregnancy, and the symptoms indicated generally a subacute febrile condition. There was no disease of the heart. About a fortnight before, Mrs. K. got a chill, when heated and perspiring, after which the œdema first came on. The rapid increase in the size of the abdomen, especially during the last two days, with the gradually increasing swelling of the legs and thighs, caused her to seek medical advice. She thought herself now about five and a half months gone, and had felt the child at times distinctly. The urine did not contain albumen, but the fæces were unhealthy, and the portal system was engorged. Diuretics and hydra-

gogue aperients were given, under the use of which the oedematous condition of the legs began to subside in three or four days; but it was remarkable, as this diminished, and at length disappeared entirely, that the size of the abdomen continued to increase to that of pregnancy at full term, attended with much dyspnoea and pains at the sides. Fomentations, linseed-meal poultices, and sinapisms, afforded some relief. On the 26th, Dr. Scott of Huddersfield saw the case with me. A large square of spongio-piline, twenty by sixteen inches, steeped in a strong hot decoction of fresh digitalis leaves, was continuously applied to the abdomen for two or three days, but without mitigating the symptoms. The size of the abdomen was now considerably larger than that of full pregnancy. The dyspnoea was most distressing, and respiration was easy only in the sitting posture, with the legs down. Large doses of bitartrate of potash, with digitalis, were being taken at this time, when about 10 P.M. of the 29th, pains like those of labour came on, and, in half an hour after, the membranes giving way, a sudden gush of several quarts of red-coloured fluid took place, with immense relief.

On being sent for, I found the child's head presenting, with the os fully dilated. The pains being inefficient, a dose of ergot was given, and about 11.30 a six months' female child was expelled dead, though it had been felt alive during the day. On removing it, I found the alar nasi wanting, and a deficiency in the anterior part of the superior maxillary bones, forming, with the nasal cavity, an irregular aperture, about an inch in diameter. Some small fragments of bone, as though broken off, were found here at its margin, while some loose skin, which had a torn appearance, was hanging from its sides. Turning to the mother, as a pain came on, I examined, expecting to feel the placenta descending, instead of which there was a firm smooth substance; and, finding the abdomen still very large, I thought it the breech of a second child presenting. I was not left long in suspense; one or two pains sufficing to bring away a large sarcomatous tumour of the colour of the skin, of an oblong cylindrical form, smooth surface, with rounded extremities, about nine inches long, and four and a half inches in transverse diameter, and weighing at least four or five pounds. Puzzled, at first, to account for its being there loose, on turning it over and over, to find its point of attachment, I discovered at one extremity an uneven torn looking surface, corresponding in size to the apertures in the child's face. The difficulty was at once solved; the presence of two or three minute pieces of bone, which were embedded in this part, making it evident that here it had been attached to the face, and forcibly torn off during the expulsion of the child. The abdomen still remaining unusually large, and the placenta not coming away, I first repeated the ergot to insure firm contraction, and then used moderate traction on the cord, which, being a thin one, soon gave way. Expecting something unusual, I placed the right hand on the abdomen, and, though there was no hæmorrhage, on introducing the left, I found the uterus occupied by a placenta of enormous size, to reach the full extent of which the hand had to enter a large constricted portion of the fundus, where it was extensively, but by no means firmly adherent. The difficulty was, that from its soft consistence it was so easily torn, that there was some trouble in removing it entire; its size also rendering it scarcely possible to grasp and sweep it out at once. It was very gratifying to find that the uterus followed it down closely, and by degrees contracted to its usual dimensions; the right hand all the while being kept on the abdomen, and contraction for some time after maintained by compression, dipping each hand alternately in cold water. The placenta completely filled an ordinary sized chamber-vessel, being remarkably soft, spongy, and readily breaking up under the finger, with about three inches of the cord left attached. A firm pad and bandage completed this singular case. There was no subsequent hæmorrhage, nor any oedema remaining in any part. Her recovery was very satisfactory.

The fetus having presented with the front towards the sacrum, the tumour would lie in the uterus, before its detachment, parallel to the child's abdomen, and pressure would thus be made on the iliac veins, causing the hydrometra and oedema of the lower extremities.

The rapid subsidence of the oedema, as the uterus filled, would appear to be in consequence of this pressure being removed, as the tumour and fetus were floated up out of the pelvis, and not altogether, as was supposed, the result of the remedies employed. As to the cause of the immense size and fragile texture of the placenta, I will leave it to those more experienced than myself in the pathology of the uterus, to offer a suggestion or to explain.

A VERY CLOSE SHAVE.—At the annual meeting of the Stockton-on-Tees Dispensary, it appeared that the income for the past year was £199 os. 7d., and the expenditure £199 os. 6d.

SURGICAL MEMORANDA.

THE POLYPUS KNIFE-HOOK.

As the communication from Mr. Buller to the BRITISH MEDICAL JOURNAL, which has been sent to me by Mr. Buller for perusal, and that of Dr. A. P. Whittell to me, a copy of which is subjoined, sufficiently answer the article on the polypus knife-hook from Mr. Lennox Browne, which appeared in last week's issue, I need not take up the space of the JOURNAL by any further remarks of mine upon the subject.

I am glad to learn that Mr. Lennox Browne has found the instrument so useful, and will have pleasure, should he call up on me here, in showing him a modification of the hook, consisting of placing the cutting hook at a different angle to the handle from that which he saw in Dr. Whittell's possession, and which enables the operator to remove growths arising from the tympanic cavity, or granulations on the membrane, to which the cutting edge of the hook he has used cannot be applied, or only in an exceptionally large measure.

W. LAIDLAW PURVES, 7, Hanover Street.

(Copy.)

"L. Purves, Esq., London.

"Dear Sir,—Your note of the 5th instant has just come to hand, and I hasten to comply with your request. The polypus hook which Mr. Weiss made for me was made following your suggestion, and I consider it a valuable addition to aural surgical instruments. I showed the knife to Mr. Browne (who used it very successfully on a case of aural polypus), saying that it was probably the first of the kind made, but that it was made after your suggestion.

"Believe me, very truly yours, "A. P. WHITTELL.

"9, Rue Gay Lussac, Paris, Feb. 6th, 1875."

THE POLYPUS KNIFE-HOOK.

HAVING seen in last week's JOURNAL a statement made by Mr. Lennox Browne, which seems to call in question Mr. Purves's claim to the invention of the polypus knife-hook, I beg to state that I was present with Drs. Frank and Whittell when the proposition was made by Mr. Purves to use such an instrument, and that Dr. Frank only mentioned having used an instrument constructed on the same principle for the operation for strabismus, during the discussion which followed Dr. Purves's proposition. I have Dr. Frank's authority for saying that he lays no claim whatever to having suggested the idea to Mr. Purves.

F. BULLER, House-Surgeon Royal Ophthalmic Hospital, Moorfields.

CLINICAL MEMORANDA.

TEMPERATURE IN PHTHISIS.

I HAD the advantage (thanks to the courtesy of Dr. Gilbert Smith) of hearing Dr. C. T. Williams's paper at the Royal Medical and Chirurgical Society. I wish to ask attention to a sentence in his after-speech. It is, I believe, correctly reported in the JOURNAL as follows: "The thermometer might sometimes detect the formation of tubercle before physical signs did; but, on the other hand, tubercle might form without any rise or fall of temperature." This being the case, may we look to Dr. Williams for some further expression of opinion as to the average frequency and character of the latter class of cases? There is room for clearer knowledge on the subject. The conclusions of Dr. Ringer's able pamphlet may be briefly stated in three of his propositions. 1. "There is probably a daily elevation of temperature in all cases when deposition of tubercle is taking place in any organs." 6. "By means of temperature (rise) we can, in many instances, diagnose tuberculation long before physical signs are sufficient." 8. "It is probable that by means of the temperature in morning we can conclude the deposition of tubercle has ceased." Dr. Ringer's exceptional tubercular cases are of meningitis. In the above extracts he uses guarded expressions; but at page 41 (2nd edition) we read: "Admitting an elevation of temperature in all cases of tuberclosis and catarrhal pneumonia, it follows that if the temperature be normal, we may conclude that the patient is free from these diseases." I need not say that this is a point of vital importance in daily practice. My own opinion has been largely formed by Dr. Ringer's writings, corroborated as they are by my own results. Will Dr. Williams favour us with additional evidence, either affirmative or negative? The sentence quoted from his speech is, *pro tanto*, a statement in the negative, for he was referring

only to tubercle in lung, and to its forming stage. The reader of the joint work of the Drs. Williams on *Pulmonary Consumption* will be aware that in it the subject of diagnosis by temperature is barely mentioned.

EDWARD MACKEY, M.D.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

MIDDLESEX HOSPITAL.

CASE OF FRACTURE OF THE BASE OF THE SKULL, WITH ALMOST COMPLETE ABSENCE OF SYMPTOMS.

(Under the care of Mr. GEORGE LAWSON.)

[For the notes of these cases, we are indebted to Mr. Fenn, the Senior House-Surgeon.]

The following case is remarkable on account of the slight symptoms produced by very extensive injuries of the skull and brain; or rather on account of the absence of symptoms, for the patient was already the subject of chronic epilepsy, whilst his restlessness and insomnia were no more than might have been expected as the result of alcoholic poisoning. At the time of his admission, Mr. Fenn, the house-surgeon, suspected fracture of the skull, but the patient stated so positively that he had often been as bad before, and the progress of the case appeared so fully to substantiate his statement, that this first diagnosis was given up, as is clearly shown by the subsequent treatment; it is, however, highly improbable that any amount of care could have led to a favourable termination of the case. No information could be obtained as to how he received his injuries.

William S., aged 42, was brought to the hospital by the police at 2 A.M., on January 1st; he had been found lying insensible in the street. On admission, he could be roused partially by loud speaking, but could not be induced to give his name and address. The only signs of injury were a slight bruise on the right side of the head and slight hemorrhage from the left ear; shortly after his admission, he had a succession of epileptic fits. In the course of the day, he gradually recovered his consciousness; but, on January 2nd, he became delirious, and manifested all the usual symptoms of delirium tremens—insomnia, violent delirium, with constant restlessness and incessant talking; he was accordingly removed into a ward by himself, and ordered full doses of opium. As this, however, produced no effect, he was, on the following day, ordered to have fifteen grains of chloral and twenty of bromide of potassium every three hours; after the third dose, he slept comfortably for five or six hours, and awoke perfectly rational, said he felt quite well, and insisted on getting up and dressing himself. On the next day, the 5th, he had another series of epileptic fits, and these continued to occur daily until he died, very unexpectedly, in a fit, on the 12th. During the whole of this week, until the day of his death, he was up and about the ward daily, and the only thing he complained of was wakefulness; he never slept except after a dose of chloral and bromide of potassium, and then only for a few hours.

The following remarkable history was obtained, partly from the patient himself and partly from his wife. He was one of a family of eleven children; of these, five died young; of five boys who reached manhood, one had since died from the effects of drink, and three out of the remaining four are excessive drinkers; they have each an annuity, and do no work, but pass their lives in a state of constant intemperance; his only sister does not drink. His father, now seventy-five years of age, is an habitual drunkard, and has been twice placed in confinement on account of insanity induced by drink.

As to the patient himself, his wife stated that she had been married to him ten years; he was a drinking man when she married him, was drunk on the wedding-day, and continued so for four or five days afterwards. Ever since then, he had, at intervals of two or three months, given himself up to a regular drinking bout, lasting from three to five weeks, during which time he would be constantly drunk; these always culminated in an attack of "the horrors", *i.e.*, delirium tremens, at the close of which he usually had a succession of epileptic fits; these gradually passed off in a few days, and he resumed his usual health. Then came a short period of strict sobriety, soon followed by a relapse into intemperance. Lately, the intervals between the drinking bouts had become shorter; during last year, he had four of them, each followed by an attack of delirium tremens, and by a recurrence of the epileptic fits.

Necropsy.—On reflecting the scalp, a quantity of black blood was found

effused in the substance of the right temporal muscle; there was also a blood-clot of considerable size between the right temporal bone and the dura mater, and blood also beneath the pia mater on the temporo-sphenoidal lobes, right and left, and in the occipital region; the cortical substance of the brain was lacerated at these points; the clots were firm and closely adherent to the bones and membranes—evidently not very recent. A linear fracture was found traversing the whole base of the skull, passing from the temporal portion of the temporal bone on one side almost directly across to about the same point on the other, through the petrous part of the temporal bone, the foramen lacerum medium and the body of the sphenoid bone. When the top of the skull was removed, the facial bones were quite loose and movable on the back of the head like a hinge. There was some congestion of the lungs, but the other organs were tolerably healthy.

CHILD CHOKED BY A CRUST: TRACHEOTOMY: DEATH.

(Under the care of Mr. CAMPBELL DE MORGAN.)

THE explanation of this case evidently is that the crust did not enter the larynx, but became impacted for a time in the pharynx, or at the entrance of the oesophagus, and thus caused secondary spasm of the glottis. The existence of a "tubercular" cavity in the apex of the lung of so young a child is also worthy of notice.

A fairly nourished and healthy looking child, twelve months old, was brought to the hospital, at 2 P.M., on December 13th, 1874, by her mother, who stated that, except for a slight cough, the child had previously enjoyed good health. Only a few minutes before, she had been lying on the floor, as well as usual, with a crust in her hand, when she was observed to have suddenly changed colour and to be gasping for breath; the crust had disappeared. The mother picked her up and hurried at once to the hospital.

On admission, the child was apparently dead, the surface of the body was cool, the face and lips livid, respiration had ceased, and no pulse could be felt at the wrist. Tracheotomy was at once performed by Mr. Fenn, the house-surgeon; and, after artificial respiration by Silvester's method had been kept up for a short time, the child began to breathe again fairly well and easily, and the natural colour returned to her lips and cheeks. Before inserting the tube, a probe was passed upwards into the glottis, but no foreign body could be felt.

The child continued comfortable during the day, except when the tube became partially obstructed by mucus, and wiping this out gently with a feather at once relieved the dyspnoea. Towards evening, there was a further improvement, and the child was able to swallow milk without difficulty.

Next morning, it was noted that she had slept quietly during most of the night and took her milk easily; the tube was removed, cleaned, and replaced.

In the course of the day, however, the little patient became feverish, and her breathing much accelerated. On auscultation, it was found that there was less breathing over the left lung than the right; towards evening, the dyspnoea became urgent, the child rapidly sank, and died about 11 P.M.

Necropsy.—On removing the larynx and lungs together, the former was found to be healthy, and there was no obstruction to the entrance of air. There were signs of acute capillary bronchitis in both lungs; the left was becoming hepatized from pneumonia, and at its apex was a cavity filled with puriform fluid and surrounded by tubercular deposit. There was considerable enlargement of the bronchial glands near the bifurcation of the trachea. The abdominal organs were healthy.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.

WOUND OF THE LEFT FEMORAL ARTERY: LIGATURE ABOVE AND BELOW THE WOUND, AND OF THE PROFUNDA: DEATH.

(Under the care of Mr. ARTHUR JACKSON.)

A. B., AGED 53, was admitted on November 11th, 1874, pulseless, and faint from loss of blood. There was a small wound two inches below Poupart's ligament, in the left thigh, over the femoral artery, caused by a knife which had slipped as he was using it. There was no hemorrhage when he was admitted, but there was abundant evidence of his having lost a large quantity of blood. He was taken to bed, and endeavours were made to cause him to rally.

In the evening, ten hours after the accident, his pulse was a good one; he was conscious, and complained of no pain. He was paralysed on his right side; was in a weak state of health; and had retention of urine, which had come on since the accident. Examination of the thigh revealed a small pulsating tumour behind the wound, which was completely closed up. The pulsation was entirely arrested by pressure

over the femoral artery as it passed out of the pelvis. There was distinct pulsation in both tibials at the ankle-joint.

November 14th. He had gone on much the same; the tumour had not become much larger, but the pulsation in it was more marked; the integument over the tumour appeared thinner. There was, and ever had been, pulsation in both tibials. The tumour was laid open with a view to ligaturing the artery above and below the wound. A large gaping wound was found in the anterior surface of the femoral artery, and with much difficulty ligatures were applied above and below it. A large branch interfered with the proper application of the upper ligature, which had to be applied above it. Instead of the hæmorrhage ceasing, a fierce gush of blood followed the application of the ligature, and it was found that blood was regurgitating freely from the profunda artery, which opened into the artery immediately behind the wound between the two ligatures. The profunda artery was then tied, and all bleeding ceased.

November 21st. He died, having sunk gradually from exhaustion due to the loss of blood and his paralysed condition. The foot was warm to the end; there was no evidence of gangrene, and the wound appeared healthy. There was no pulsation in either tibial.

Examination of the artery showed that the internal coagulum had formed thoroughly. A thorough examination of the body was not allowed.

Guthrie, in his *Commentaries on Surgery*, p. 273, suggests the possibility of this accident happening, but does not appear to have seen such a case. He is evidently of opinion that the profunda artery would not bleed at the time of the operation.

REVIEWS AND NOTICES.

THE TRUE ACTION AND PHYSIOLOGICAL RESULTS OF ALCOHOL.

By T. P. LUCAS, L.R.C.P.Ed. London: 1874.

IN this little work, Dr. LUCAS proposes a new theory of the action of alcohol. He thinks that all medicines produce their effects by acting upon the cerebro-spinal or on the sympathetic system of nerves. Those agents which determine the former to act are *pure stimulants*; and the latter, narcotics. Alcohol is a stimulant in all its doses; but, during its passage through the body, the whole or a large part of it splits up into carbonic acid and water, and to the retention of the carbonic acid in the blood he attributes the narcotic effects of the alcohol, since this agent acts upon the sympathetic system of nerves. Dr. Lucas cannot imagine that a small dose of alcohol can produce stimulation, while a larger dose produces depression. "To affirm that alcohol stimulates and then depresses a nerve, is surely," he says, "utter nonsense, or mere dogmatic assertion." It will probably serve no useful purpose to remind a gentleman who is so extremely self-satisfied as Dr. Lucas, that, as a matter of fact, a small current of galvanism increases the irritability of a nerve, that a stronger decreases it, and that a still stronger annihilates the irritability for a time, and all this occurs without the intervention of carbonic acid; and we cannot help thinking, Dr. Lucas notwithstanding, that the assertion that a small current of galvanism increases the irritability of a nerve, while a strong current annihilates it, is as much nonsense as, and no more so than, the assertion that a small dose of alcohol stimulates nervous tissue, while a large dose destroys its irritability, or narcotises. The reader will find no lack of new theories upon other subjects in this book. The results obtained by Dr. Magnan of Paris by absinthe is thus explained. The alcohol acts upon the origin of the pneumogastric nerve, and the active principle of the absinthe on the terminations of the same nerves in the stomach. "The currents caused by the severe stimulants to the extremities of the nerve would," according to Dr. Lucas, "meet, and together produce epileptic symptoms". We have also a new application of the germ-theory of fermentation. The effect of alcohol upon the liver and intestinal canal is such, that "the bile so eliminated is not reabsorbed in a natural quantum, or, if reabsorbed, only acts as a depressant, and by affording *germs* of fermentation as a source of mischief to the blood, and to the system generally".

In another place, a piece of information is volunteered which is new to most of us. "The more depressed the vital powers are," he says, "the more slow the generation of pus; and, therefore, the longer must nature be in accomplishing the purpose for which pus is generated." We shall leave these new doctrines to the judgment of the reader. We may, however, be permitted to express a hope that, whenever Dr. Lucas favours the profession with a new edition of his work, instead of boasting, as he does in his present preface, that he could only devote a few months to his essay (which, by the way, was sent in for the Hastings Gold Medal last year), he will be able to say, that he has

given the subject the most careful attention for many years, and that he has at least endeavoured to understand and to do justice to the views of others; in that event, he may be able to produce a book which will be really worth reading.

REPORT OF THE SANITARY COMMISSIONER FOR MADRAS, 1873.

THOSE who are interested in the progress of sanitation in India always look with interest for Dr. CORNISH's Reports, for, as a rule, they contain within reasonable limits a large amount of well digested information. The year 1873 seems to have been a healthy one in Southern India; the abnormal rainfall of 1872, while it seems to have influenced the production of malarious fevers amongst the native population, appears to have had little effect in this respect on the well-protected European soldier. We ask the attention of anti-vaccination fanatics, and their supporters, in and out of Parliament, to the following fact. Small-pox was widely diffused, and fatal throughout the native population; but, in the European army, carefully protected by vaccination, there were only six cases and one death.

There was an outbreak of enteric fever at Cannamore, the cause of which was investigated by Dr. Cornish and Deputy Surgeon-General Massy; so far as we can judge, from Dr. Cornish's Report, without any positive result. We regard this part of the Report as unsatisfactory. Dr. Cornish admits that the barracks and surroundings were not perfect, and he says that suggestions were made for remedying "the more obvious of the sanitary defects observable". On this we would remark, that we have a right to look for something more than this from a sanitary commissioner. It is easy to see the "more obvious" sanitary defects of barracks and their surroundings; but when two such important sanitary officers as a deputy surgeon-general of a division of the army, and the sanitary commissioner of the Presidency, are sent to investigate the cause of an outbreak of enteric fever, we think that a more searching inquiry was called for, and that the less "obvious" defects in all probability required remedying, perhaps, more than those seen on the surface. We are surprised, also, at the slight way in which Dr. Cornish writes about the uncovered wells exposed to fecal defilement; and we can only say that, in an inquiry directed to such a purpose as this in this country, so suspicious a fact would not have been lightly regarded. We have understood that Dr. Massy, who was associated with Dr. Cornish in this investigation, is not satisfied with the manner in which Dr. Cornish has presented the facts in this Report.

We notice with regret that dysentery has been more fatal during the past year under notice than it was twelve years ago. In 1873, there were 32 deaths out of 1038 cases treated; a mortality exceeding 3 per cent. As usual, Secunderabad, of dysenteric notoriety, furnished more than one-half of the fatal cases. Twelve years ago, when practitioners in Southern India returned to the practice of administering ipecacuanha in full doses, the mortality fell from seven to two per cent. of those treated; and Dr. Cornish suspects, we fear with reason, that in the constant succession of medical officers new to India, the indisputable power of this remedy is to some extent overlooked. If this be so, the sooner the attention of administrative medical officers is called to the fact the better. If there be any want of due appreciation of the remedial power of ipecacuanha in dysentery, it must be among the older officers going to India late in life: for it is certain that this vital part of tropical therapeutics is pressed on the attention of young medical officers in the army medical school with sufficient earnestness.

Dr. Cornish dwells also on the fact, that hepatic abscess diminishes in proportion to the success with which acute dysentery is dealt with in its early stages. This is indisputably true, and those whom it concerns should keep it constantly in mind. The total number of troops invalided from the Madras Presidency was 717; of these, 150 were considered unfit for further service, while 567 were sent home for change of climate. The main causes were dysentery 121 cases, debility 124, hepatitis 95, phthisis 83, secondary syphilis 40, rheumatism 32, diseases of heart and blood-vessels 74 cases. The ratio per 1000 of strength was, for final discharge 15.32, for change of climate 49.90, being the largest numbers invalided for the last named purpose since 1860.

In the appendix to the Report, there is an interesting paper on the alleged improvement in the value for assurance purposes of European life in India. Dr. Cornish's investigation, so far as it goes, supports the opinion put forth by Dr. Mouat and Lord Sandhurst on general grounds, that the value of life in India has increased and is increasing. Instead of 69 per 1000 for all India, the death-rate in the European army is now in the three Presidencies 28 per 1000, while, as regards Bombay and Madras, it is 22 per 1000. In the civil service of the Madras Presidency, the mortality has fallen in the last twelve years from 14.1 per 1000 to 11

per 1000. In the Madras medical service, the mortality rate for the last twelve years has been very low, viz., 6.4 per *mille* for the ages below 30; from 30 to 40, the mortality stands at 15 per *mille*; and from 40 to 50 it is less than for the earlier decennial period, being only 10.5 per *mille*. The mortality rate in the staff corps for the last twelve years has been 18.04 per 1000. Dr. Cornish adds, "there can be no question but that the official classes in India have been much less liable to die from cholera, fevers, and dysentery of late years. As regards the first of these, the hygienic conditions have improved; and, in regard to the two latter diseases, medical treatment has advanced and materially diminished the risks of life."

SELECTIONS FROM JOURNALS.

MIDWIFERY AND DISEASES OF WOMEN.

HOT WATER INJECTIONS IN UTERINE DISEASES.—Dr. T. A. Emmet, in an article contributed to the *New York Medical Journal*, July, 1874, says that the prolonged use of hot water vaginal injections is followed by tonic contraction of the arterioles, thus bringing about an approach to healthy action—the immediate effect of heat being dilatation, the secondary contraction. He recommends, as the best method of obtaining the contractile effect, that the woman be placed on her back, with the hips elevated by a properly shaped bed-pan under her, and that a gallon or more of water at 98 deg. Fahr., or higher temperature, be slowly injected into the vagina with a David-son's syringe. The mucous membrane becomes blanched, and the size of the canal is diminished, just as if a strong astringent had been applied. With the hips elevated, the vagina will retain a large quantity of the water, which also, by its weight, distends every portion of the canal, so that it will come into contact with the entire mucous membrane, under which the capillaries lie. The vessels of the cervix and body of the uterus pass along the sulcus on each side of the vagina, and their branches encircle the canal in a most complex network. The vessels of the fundus, through the veins of which the blood passes by the liver back into the general circulation, anastomose with those below. Thus, the whole pelvic circulation may be influenced, directly or indirectly, through the vagina. We can so diminish the supply of blood as not only to check congestion, but we can literally starve out an inflammation. Dr. Emmet states that, from his own observation, several injections a day at 100 deg. to 106 deg. Fahr. will avert an attack of cellulitis, if early used and persevered in, with the aid of rest and anodynes. These injections also exercise a most beneficial effect upon the reflex system, by allaying local irritation. He knows no better means for removing the nervousness and sleeplessness of hysterical women than prolonged hot water injections. To receive permanent benefit from their use, they must be continued once a day, preferably at bedtime, until the patient's health is restored. He thinks the patient cannot administer them properly herself—no arrangement can take the place of an intelligent nurse. As the patient improves in health, the quantity of water can be diminished, and the temperature lowered, until the injections are discontinued from daily use; but for some time they should be employed for a few days after each menstrual period.

INJECTION OF HOT WATER AS A MEANS OF ARRESTING UTERINE HÆMORRHAGE. Dr. Windelband of Berlin writes in the *Allgemeine Medicinische Central-Zeitung*, for January 27th, that his attention was called by the perusal of an article by an American practitioner, to the effect of injections of hot water as a means of arresting hæmorrhage from the uterus. In a case of abortion with alarming hæmorrhage, for the restraint of which ergot and cold water injections had failed, Dr. Windelband injected water at about 100 deg. Fahr. Within a short time, or rather at the moment of entrance of the fluid, such energetic contraction of the uterus took place, that the ovum, which could but just be felt within the open os uteri, was ejected with its membranes from the uterus in a quarter of an hour. For some days, he repeated the injections when there was any indication of bleeding, and afterwards continued them at a lukewarm temperature until involution of the uterus was complete. He says that he has used injections of hot water with the best results in a number of cases which have occurred in his practice during the last year; including twenty-one cases of abortion, two cases of severe hæmorrhage from placenta prævia, cases of hæmorrhage attending fibroid and other tumours of the uterus, cases of carcinoma, of *post partum* hæmorrhage, of profuse menstruation, etc. He is convinced that the hot water exerts a far more energetic action in the muscular structure of the uterus, than cold water, either alone or with astringent remedies in solution. He makes

the injections with an ordinary uterine douche, the water having a temperature varying from 95 to 100 deg. Fahr.; and has never found any disadvantageous results.

NITRITE OF AMYL AND BELLADONNA IN DYSMENORRHOEA.—Dr. Mary Putnam Jacobi, at the meeting of the New York Medical Journal and Library Association, November 27th, 1874, read a paper on this subject, detailing three cases of severe spasmodic dysmenorrhœa to illustrate the method of operation of these remedies. The argument in support of this treatment was founded upon data furnished by the second case, viz.: (1) vomiting, pallor of skin, cold hands and feet; (2) extraordinary peristaltic action of the intestines; and (3) spasmodic pain in the uterus. All of these pointed to one element, that of spasmodic contraction of blood-vessels. The so-called sympathy between the uterus and the stomach, and between the stomach and brain, were considered in their dependence and interdependence with reference to vomiting. Reasoning from the experiments of Schiff and others, it was believed that the vomiting of pregnancy, of sea-sickness, and of many cases analogous in character, was due to anæmia of the brain, producing spasmodic contraction of the blood-vessels at its base. It was also argued that anæmia of the intestines produces increased peristalsis, due to spasmodic contraction of blood-vessels. The conditions in which a hollow muscular organ can contract in the state of vacuity are: After direct irritation (1) of its nerve; (2) of its muscular fibre; and (3) after changes in its circulation. Six experiments upon rabbits were detailed. The abdomen was opened, the intestines drawn out and carefully protected in a bag of oiled silk immersed in a vessel of warm water; the uterus and abdominal aorta were exposed. The aorta was ligated; several peristaltic waves ran down the rectum, but never in a contrary direction. Contraction of the uterus occurred, and was distinctly visible at the middle third of the organ. Upon removing the ligature, the contractions ceased. The conclusion drawn from the experiments was that tonic uterine contractions may be excited by occlusion of the aorta, and that such contractions continue from one to four minutes after compression has been removed. Clonic contractions also occurred, after the type of contractions of masses of smooth muscular fibre. The bearing of these experiments upon the treatment of spasmodic dysmenorrhœa, is that the pain is dependent upon tonic and clonic contractions of the uterus. These in turn are due to changes in the circulation of the uterine walls. If the change of the blood-vessels pass to an irritation, spasmodic contraction must take place, and uterine contractions will be determined by local anæmia. Spasmodic contraction of blood-vessels resulting from irritation of vaso-motor nerves is the cause of the pain of spasmodic dysmenorrhœa. It is upon these considerations that the remedies suggested are used. The secondary effect of belladonna is dilatation of the blood-vessels. It is to be administered, therefore, for several days previous to the occurrence of menstruation, so as to obtain its secondary effects. Nitrite of amyl is used to relax blood-vessels, in accordance with its admitted physiological action; and, therefore, it is administered (by inhalation, two or three drops *pro re nata*) when pains came on. In one case, a single drop of amyl was all that was required. This method of treatment is, of course, more especially adapted to cases of spasmodic dysmenorrhœa; but it has been found, both in the experience of the author of the paper and in that of others, that great relief may be afforded, even in those cases in which the dysmenorrhœa depended upon displacements, constriction of the cervix, etc. Dr. Sell remarked that he had been in the habit of administering amyl (one-drop doses with one drachm of peppermint water, repeated every half hour) by the mouth, and had obtained just as good results as when the remedy had been inhaled. However, he had used the nitrite of amyl in only one case of dysmenorrhœa, and in that case the pain was completely relieved.—*New York Medical Record*, January 2nd, 1875.

MEDICINE.

COLD BATHS IN CEREBRAL RHEUMATISM.—In the *Journal de Thérapeutique*, No. 22, 1874, M. Raynaud reports the case of a very strong, vigorous, and sober man, aged 32, who was attacked by rheumatism affecting many of the joints. Two days afterwards the pains left him entirely, but very serious cerebral symptoms came on; and in two days, when M. Raynaud saw the patient, the pulse was 120 and the rectal temperature 104.9 Fahr. M. Raynaud bled him to more than two pounds, but the temperature and pulse still remained high. M. Raynaud, therefore, ordered cold baths. One a little above 60 deg. Fahr., was ordered to be given, at 11.28 A.M., to last half an hour. When the patient left the bath, his temperature had fallen to 100 deg. Fahr., his pulse to 76, and consciousness, which had been lost, seemed returning. At 3.30 P.M. the temperature rose to 101.66 Fahr. Another

half-hour's bath was ordered, during which the exhaustion was considerable. After the bath, the rectal temperature was 97.5 Fahr. At 8.30 p.m., the temperature reached 100.4 deg. Fahr. Another bath was given, after which the rectal temperature was 98.8 deg. At 11 p.m., consciousness returned, and the patient passed the night in quiet sleep. On the succeeding day, three cold baths were given, and were followed by a similar lowering of the temperature. At the end of this day's treatment, the patient had regained his consciousness: asked for drink, and slept quietly. On the third day, he had two baths, and a final bath on the fourth day. From that time, the temperature never exceeded 99.14 deg. Fahr., even in the evening, and convalescence set in decidedly. The cerebral symptoms in this case must be attributed in this case to that meningitic form of cerebral rheumatism characterised by the advent of delirium and coma. But the appearance of the meningitic form, in the author's opinion, is purely symptomatic; for it cannot be supposed that an attack of meningitis could be instantly influenced by a cold bath.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, FEBRUARY 13TH, 1875.

THE NEW NAVAL MEDICAL WARRANT.

WE find ourselves in the enviable position of being able to congratulate our profession in the Navy on the Royal Warrant signed on February 4th, which has assigned to the qualified practitioner who devotes himself to service in the Royal Navy the position, which is unquestioned in civil life, of equality with the clergy and those who adopt the profession of instruction of the rising generation in their service. This we accept as the corollary of the Medical Act of 1858, which prevents the State from employing in its service any other than legally qualified practitioners. That principle being once made the law of the land, it has proved but a futile and unavailing attempt to delay, if not to prevent, its logical development. Young medical men, on entering the Navy, are placed of right in their proper position; and this is a point gained, which must act beneficially on the service at large, as much as on the medical branch of it. We would that, on this occasion, the Admiralty had gracefully conceded in full, instead of in part, the privilege of retiring after twenty years on the *half-pay earned*. We fear that this will remain the blot of the Warrant of 1875, as it was that of the Warrant of 1866.

Another point for congratulation is, that those who have worked faithfully to the last, and have gained the honours of the service, are placed, on their retirement, in a position of comfort and independence that will enable them to show such examples of professional success as will, more than anything else, induce those who have entered the service to work on cheerfully and zealously to attain to similar rank and position. Henceforth this will, we trust, prevent the lamentable display, so common of late, of efforts, *per fas aut nefas*, to escape from the irksome trials of a protracted life at sea. The present Government has done well in reversing the error of the last Naval Administration in disregarding entirely the claims of our profession on this point; but, in reducing the period of service below that which exists in the Army, we have no doubt that the generosity of the present Administration will intuitively guide them in doing justice to those who are injured by this decision in their established prospects of the future.

These we have good reason to regard as the sum of the gains in the direction of the representations made by the deputation from the Committee of the British Medical Association, which waited on the First Lord in June last. We must, however, point out that many of the representations made there do not bear any fruit in the present Warrant. These may be summed up under the one comprehensive head of "the substantive equalities of relative rank", both while serving on board ship and in such positions on shore as the necessities of the service may require; viz., contingent allowances of every

COLUMN FOR THE CURIOUS.

THE WHIPPING-POST AND DUCKING-STOOL.—In consulting an old surgical book in the library of the Medical Society, I find the following tale.—"One Thomas Leddle, the late apprentice, writes to his master, John Martin, surgeon being written on the door, at his house in Hatton Garden, on the left hand, beyond the chappel, turning in from Holborn, May 1708.—A man of good reputation in this town (Gosport) happened to suffer a certain (as he thought modest) woman to lodge in his house, who, for a few nights (for want of present conveniency elsewhere), lay with his son, a very harmless, silly lad, about the age of eight or nine years; the woman, in the night, drew the child several times into the place of her husband. In three or four days' time after, the child, by his crying when he made water, gave cause for inspection, and there was visible inflammation of the organ, and a painted shirt. The lad at first bore examination without any manner of confession for some time, because he was obliged to secrete; but (as is usual), when he began to speak to the purpose, was as free as above reserved. 'Twas plain how the matter was; but, for more satisfaction and proof, the woman was searched, which gave a fatal blow to all her excuses, for she was sentenced to the whipping-post, where she had justice tipped her very severely, and from thence to the ducking-stool, when she just escaped alive." Can any of your readers tell me if this was the sort of punishment formerly meted out to women who misconducted themselves? Who were the parties who passed the sentence and "tipped" this justice?—WILLIAM ACTON.

EMBALMING.—The following will, no doubt, be read with some interest, as an addition to the notice published in the JOURNAL. In Rymer's *Federa*, vol. i, will be found a letter from the Keeper of the King's wardrobe, to Sir Ralph de Stoke, Clerk of the Great Wardrobe, stating that Richard de Montpelier, the King's Spicer (Espicer), was going to London on account of the King's illness, and desiring that every facility might be afforded him to procure and make up the medicines—"Propter infirmitatem domini regis per ordinationem Magister Nicolaus de Tynwyck." Richard de Montpelier's little bill for this illness and subsequent embalmment amounted to £134:16:4, a considerable sum in those days. Amongst other curious items will be found the following, viz.:

Pro emplastris cironeis	£ 4 : — : —
Item pro terebintine distillato	— : 40 : —
Item pro uno emplastro pro collo regis cum ladano et ambrais orientalis	— : 60 : —
Item pro vij malis granatis	— : 60 : —
Item pro sex uncis de balsamo ad corpus domini regis unguendum	13 : — : —
Item pro musci uncia iij ad ponendum in mem- bris regis	— : 60 : —

The late Mr. G. J. Squibb, who wrote on this subject nearly a quarter of a century ago, states a curious fact with relation to the embalming of Edward the First, which will prove that Master Nicolas of Tynwycke, Master Peter, and Richard of Montpelier, the Espicer or Apothecary, did their duty well; for, about fifty years ago, the tomb of Edward was opened, and the body found entire. A zealous antiquarian, Sir J. Ayscough, was induced to taste the *pickle*, or fluid in which the royal body was preserved, and, even then, more than five hundred years after the embalmment, it showed traces of the spices used by Richard of Montpelier.

kind, and the recognition of the claims of widows and fatherless children. On these important points, we are, however, advised that it is within the authority of the Admiralty of itself to effect the required changes, independently of Royal Warrants; and we shall anxiously look to the Admiralty circular which must necessarily soon appear, to learn that these have not been disregarded in their deliberations. The medical profession has in this instance given a fresh proof of its power in vindicating its rights, and has obtained consideration; and on that fact, among others, we rely to prevent the repetition of all those former practices that undermined the value of previous concessions made to medical officers. The naval authorities have deemed it wise to endeavour to unite the sister services in their infancy. While at the top of the ladder, they have contrasted them, in making the headship a thing apart from the active service, and in shortening the career of the highest grades. Although the provisions now made have not the elements of finality in them, yet they are a long step in the right direction: probably some years may elapse before another is made. But we can now confidently recommend the students of the day, who have a predilection for a sea-life, no longer to abstain from accepting the terms now offered, which have at least the effect of removing all obstacles from the threshold of their career.

ARTISANS' DWELLINGS BILL.

Mr. Cross's proposed Bill for the improvement of the dwellings of the working classes in large towns may be considered as a fairly moderate measure; for, while he insists on the rights of the poor to be decently housed, he does not ignore vested interests or the rights of property. Fever-dens must be demolished, but equitable compensation will be allowed to the owners, who will still retain their right to rebuild tenements, but under such moderate supervision as shall ensure suitable sanitary requirements.

In asking permission to introduce the Bill, the Home Secretary gave the result of careful study and close observation of the poorer class of dwellings in the various large towns of the kingdom. From these observations he deduced the trite conclusion, that what the houses of the people were, the people themselves would be found to be.

Notwithstanding all that had been done by private enterprise and public legislation under the Act of the member for Finsbury (Mr. McCullagh Torrens), and the Bill which enabled corporations to give up lands and borrow money for the purpose of building houses for the working classes, accommodation had only been provided for 30,000, whilst the population had been increasing at the rate of 40,000 *per annum*. Something, therefore, must be done to remedy this evil. The State had a right to interfere in sanitary matters. Politically speaking, health was wealth; and it was not only the present generation that suffered from bad physical surroundings, but the stamina of future generations, and also the waste incurred in connection with gaols, lunatic asylums, and places of that kind, in addition to the loss caused by sickness and death. When the death-rate varied from 22½ or 24 per thousand in a healthy district to 38, 67, and even 70 in overcrowded courts and alleys of large towns, it was evident that something was wrong. If Government could put a stop to such a great waste of energy and life, it was their duty to do so.

The injury arose in a great measure from overcrowding. In St. Giles's, there were not fewer than seventy streets without any open central thoroughfare, to which scarcely a breath of air could enter. The condition of the houses was such, that the walls were actually ingrained with disease. No amount of money could make such dwellings healthy, and the only practical way of dealing with such houses, was to pull them down. Some of these dwellings were built on saturated ground, from which arose deadly miasmata.

In Liverpool, Glasgow, and Edinburgh, great improvements had been made by opening up these narrow courts and alleys, and letting in the light and air; and, by driving a large street through an unhealthy district, and by reselling the adjacent property at a profit, they lightened the burden to the ratepayers. The full benefit of these measures could only be felt after a lapse of time, although the decrease of serious offences had been already considerable. The class of houses, however, which had been built, was not in all cases equal to what was expected; and it was necessary that, when houses were allowed to be pulled down, due sanitary precautions should be taken, in order that those which were built in their place should not relapse into the condition of the old ones.

The measure proposed to remedy these evils, was intended to deal at first only with those towns which had a population of 2,500. The Act could not be carried out by private individuals. In London, the City authorities would be responsible; the Board of Works for the metropolis; and the respective Town Councils for each large town. It was not intended to give Town Authorities the opportunity of building showy streets. The working of the Act, therefore, would be entrusted to the medical officer, who would be bound to report upon any district which he might deem unhealthy, and whether the prevalence of disease was attributable to the bad condition of the houses. The Local Authority, on receipt of such report, would satisfy themselves of its correctness, and devise the remedy, by exercising their compulsory power of purchase, and by providing for so many of the poor inhabitants who would be removed. Important sanitary reforms would thus be effected, the population properly housed, and the whole character of a locality altered satisfactorily.

The Government did not propose to give power to take property without parliamentary sanction. In London, the scheme for compulsory purchase must be submitted for approval to the Home Secretary, if found desirable. He would pass the measure through the House, and thus avoid the enormous expense of a private Bill. A similar plan would be adopted for boroughs by the President of the Local Government Board; but it was not intended to interfere with the action of the local authorities in any way. The value of the property taken would be determined by the English Lands Clauses Act, except when arbitration was agreed upon; and the owner would have the right to appeal to the law in cases where he felt his interests had been unfairly dealt with. Powers would be given to the corporations to let, lease, or deal with the land thus acquired, and ample borrowing powers would be conferred upon them; but the buildings themselves were to be erected by private persons.

The foregoing contains the substance of the Home Secretary's proposed Bill, which must be regarded as a sound and judicious measure, from which much may be hoped, if it be not spoilt in passing through the Lords. Mr. Cross is wise enough not to expect too much from it at first. The evil it was intended to remedy has been the work of generations, and the labour will be one of time; and, although the ratepayers will probably in the end finally be more than recouped, it will at present be a work of great expense.

The most obvious objection to the Bill was at once made by Mr. Kay-Shuttleworth, who thought that the provision of the Act seemed to hinge on the action of the medical officers, who received their appointments at the hands of vestrymen, who were frequently the owners of property against which the medical men would have to report. That objection will have to be very seriously considered. Vestrymen and members of Local Boards are frequently great offenders against sanitary laws, and a medical officer desiring to do his duty in this matter must occasionally be sorely beset. Some power of appeal must, therefore, be given by which the medical officer will be protected, and by which also inhabitants who feel that the report of the medical officer falls short of their just expectations may obtain a reversion of the report. A power of appeal and revision is, in fact, urgently needed. Moreover, the machinery to put the medical officer in motion is too cumbrous. Six householders have been found to be too many in pre-

vious Bills; twenty is certainly too many for the present purpose. Again: the mode of defining areas is defective in this Bill.

The Bill is capable of a good deal of improvement in many ways; and of this the opportunity will be afforded in committee; but, on the whole, it is a wise, well considered measure, and one which will, we trust, pass into law.

THE QUARTERLY RETURN OF THE REGISTRAR-GENERAL.

DURING the three months ending September 30th, 1874, the registered number of persons married in the United Kingdom was 119,424, giving an annual marriage-rate of 14.6 per 1,000 persons living. In England, the rate was 16.4 per 1,000, and was slightly below the average. A decrease of marriages was especially marked in the counties of Cornwall, Suffolk, Warwick, Leicester, Cumberland, and Monmouth; and there was a considerable increase in Herefordshire, Lincolnshire, Durham, and South Wales. The rate varied considerably, from 10.6 per 1,000 in Suffolk to 19.1 in Northumberland; it was high among the mining populations of the northern counties, and was lower than usual in most of the agricultural counties.

During the quarter that ended on December 31st, the births of 275,754 children were registered in the United Kingdom; the rate being 33.8 per 1,000. In England, the birth-rate for the quarter was 35.6 per 1,000, a higher rate than has prevailed in any preceding corresponding quarter since civil registration was established in 1837. The rates in the agricultural and mining counties showed the usual wide divergence; it was only 26.9 in Dorsetshire, 28.0 in Herefordshire, and 30.1 in Cornwall, whereas it was so high as 45.8 in the county of Durham. In the eighteen largest English towns, the rate was 2.4 in excess of the rate in all England. It was so low as 22.6 and 23.6 in Bath and Cheltenham, and as high as 47.9 in Wigan and Gateshead.

During the quarter that ended on December 31st, the deaths of 186,947 persons of both sexes were registered in the United Kingdom, and the death-rate was 22.9 per 1,000. In England, 142,084 deaths were recorded, equal to an annual rate of 23.8 per 1,000, which considerably exceeded the rate in the last quarter either of 1872 or 1873, was 1.6 per 1,000 above the average, and, compared with the last quarter of 1873, showed an increase of 9 per cent., due in great measure to the effect of the low temperature during the latter part of November and throughout December. The death-rate was lowest, 17.5 and 18.8, in the south-eastern and south-western counties, and highest, 27.6 and 29.6, in Yorkshire, and in Lancashire and Cheshire. Amongst the thirteen and a half millions of persons residing in the chief towns of England and Wales, the annual death-rate last quarter averaged 26.7; while in the remaining, or rural population of about ten millions, the death-rate was not more than 19.9. These rates exceeded the average by 1.9 and 1.3 per 1,000 respectively. The general urban rate exceeded the rural rate by 6.8 per 1,000; in other words, the deaths of 23,382 persons occurred in the town districts who would have survived if the death-rate had not exceeded that which prevailed in the rural districts.

In the eighteen largest English towns, the death-rate exceeded the general urban rate by 1.6 per 1,000, and ranged from 19.2 and 24.8 in Portsmouth and Bristol, to 32.9 and 38.0, respectively, in Manchester and Liverpool; the death-rate from the seven principal zymotic diseases ranged from 1.5 per 1,000 in Bristol to 10.4 in Liverpool; the proportion of deaths under one year to births registered, was only 113 per 1,000 in Portsmouth, whereas it was 247 in Liverpool; and the annual death-rate per 1,000 among persons aged upwards of sixty years, varied from 83.9 in Wolverhampton to 162.8 in Liverpool. The death-rate was low, 16.2 in Rochester and Chatham, and 16.7 both in Dover and Devonport; high at Gateshead, where it was 32.1, Ashton-under-Lyne and Preston each 33.1, Carlisle 37.9, and highest, 39.6, in Dudley. The high rate in Carlisle was due to the remarkable fatality of zymotic diseases. Infant mortality in urban and rural populations

showed the usual wide divergence; and was again highest in Leicester-shire. As the excess of deaths last quarter was principally due to the long period of low temperature in November and December, it is natural to find that the rate of mortality among elderly persons was unusually high. The deaths of 36,115 persons, aged sixty and upwards, were recorded, equal to an annual rate of 81.1 per 1,000 persons estimated to be living at those ages. During the first five weeks of last quarter, the annual death-rate among persons aged over sixty years, averaged 62.5 per 1,000 in London, whereas, during the last five weeks of the year, the rate was so high as 141.7. Those living in towns, especially in Salford and Liverpool, suffered from the cold more severely than rural populations. Of the deaths registered during the quarter, 21,601 were referred to the seven principal zymotic diseases; equal to an annual rate of 3.6 per 1,000, against 2.9 and 3.2 in the two preceding corresponding quarters. This increase was entirely due to the fatal prevalence of scarlet fever. The excessive fatality of these diseases was principally confined to urban populations; the rate was so high as 6.1 in the counties of Lancashire and Cheshire, and was 7.9 in Hull, 9.3 in Dudley, 10.4 in Liverpool, and 17.3 in Carlisle. Scarlet fever caused 8,562 deaths, a higher number than in any quarter since the fourth of 1870, when 11,746 were returned. The deaths from the disease appeared to be declining in December; it may, therefore, be hoped, that the crisis of the present epidemic is over. A high rate of deaths from fever prevailed in Lancashire during the quarter, and was due in great measure to the epidemic of typhoid fever in Over-Darwen, from which 127 deaths were registered. The fatal cases of diphtheria were excessive; especially in the South-Eastern Registration Division.

The natural increase of population in the United Kingdom, produced by the excess of births over deaths during the quarter, was 88,807; and in England that increase was 70,283. Cold weather prevailed from October 2nd to the 9th; then the weather was warm for forty-two days, viz., from October 10th to November 21st, when commenced the cold period of forty-two days with which the quarter ended. During these forty-two days the mean temperature of the air at Greenwich was 35.5 degs., or 6.6 degs. below the average. The rainfall of the quarter was 7.2 inches, and 0.2 inches above the average. "The prices of wheat, potatoes, meat, and coals, fell considerably."

"The returns of the year 1874 are now complete; the mortality had been low through winter, spring, and summer; so, notwithstanding the autumn losses, the mortality of the year was at the average rate; the birth-rate was higher than it had ever been before." "Lancashire still remains remarkable for its high mortality. Over-Darwen offers an illustration of some of its sanitary defects, to which the natives appear to be accustomed and reconciled. Improvement would soon be apparent, if the same admirable skill, which has hitherto been expended on cotton-yarn, and other manufactures, could be devoted everywhere to the production of healthy dwellings. Can this county yield no leaders in such a beneficent movement?"

DR. PYLE has been placed on the Commission of the Peace for the borough of Sunderland.

DR. BATEMAN of Norwich has been elected "Membre Associe" of the Société Médico-Physiologique de Paris.

THE Hunterian Oration will be delivered this day (Saturday), at 3 o'clock, by Mr. Le Gros Clark, F.R.S., in the theatre of the Royal College of Surgeons.

WE are sorry to hear that Mr. W. Smith, senior surgeon to the Manchester Infirmary, and Professor of General Anatomy and Physiology at Owens College, died suddenly on Wednesday last of heart-disease.

IT will be seen that the library of the late Dr. Lankester is announced for sale on Tuesday, February 16th, and the two following days, by Messrs. Pattick and Simpson.

We are requested to state that, at the meeting of the Clinical Society, which will take place this evening (Friday), the newly elected President, Sir William Jenner, will deliver his inaugural address. It will be remembered that, at the time of the last meeting, Sir William Jenner was prevented from doing this by being detained at Osborne in attendance upon Prince Leopold.

At the tercentenary anniversary of the University of Leyden this week, the honorary degree of Doctor of Medicine was conferred on Mr. Darwin, Dr. Bunsen, and Mr. Spencer Wells. An honorary degree was also conferred on Dr. Olding.

The Lord Chancellor has added the names of Dr. James Coombs, ex-Mayor, and Mr. Moses Rogers, retired Deputy Inspector-General of Hospitals, to the Commission of the Peace for the Borough of Bedford.

The inhabitants of Manchester have set on foot a movement for establishing a hospital for consumption and diseases of the throat, on a similar basis to that of the Consumption Hospital at Brompton, the patients contributing towards the funds in accordance with their means. The scheme has been taken up with spirit by the "Manchester men".

THE HAMSTEAD HOSPITAL.

The President of the Local Government Board received this week, at Gwydyr House, a deputation from the Willesden Local Board, who wished to protest against the alternative scheme suggested to the Metropolitan Asylums Board, of erecting their hospital for contagious diseases in Mill Lane, Edgware Road, on the borders of the Willesden parish, instead of the Hampstead site. In answer to the objections set forth by the deputation, Mr. Slater-Booth said that he had not yet heard whether the Asylums Board intended to take up the Willesden scheme or not.

THE QUARTERLY RETURNS OF MARRIAGES.

We heartily concur in recommending to the notice of the Registrar-General, the suggestion contained in an article in the *Times*, that the returns of marriages for each quarter should be published coincidently with the returns of births and deaths for the same quarter. There exists apparently no cause for the delay in the publication of the marriages solemnised, which cannot be easily rectified; since the registration of a marriage forms almost an integral part of the ceremony. The advantage to be gained by the collection of the vital statistics for each quarter in one and the same publication, are manifest; and "the general working of the Register Office is so good, that the defects of the present arrangement are rendered prominent by contrast."

CHLOROFORM DEATH: RESUSCITATION BY NILTON'S METHOD.

DR. FREUZAL reports (*Progrès Médical*, January 30th) a case in which a child, apparently dead from the administration of chloroform, was recalled to life by inversion and suspension by the feet, and forced movements of the chest. The case forms an interesting pendant to those related at length in our columns recently by Dr. J. Marion Sims and Sir J. Rose Cormack. The lips and face were discoloured, and there was neither heart-action, pulsation, nor respiration. The effect of inversion was very rapid, and markedly effective.

EXPERIMENTS ON ANIMALS.

The Society for the Prevention of Cruelty to Animals have made an application to the various medical schools and colleges asking that "Mr. Colam and two other persons", be admitted as "mute spectators" of any "vivisections which may be practised for the purpose of research or instruction". The Royal Medical and Chirurgical Society has formally declined "the presence or interference of unqualified witnesses"; and this, we imagine, is likely to be the general course. If the Society for the Prevention of Cruelty to Animals cannot trust physiologists and physicians to report faithfully their own proceedings, it is a little surprising that they should expect medical bodies to consent to have their

proceedings publicly reported and interpreted for them by Mr. Colam and his companions. If truthfulness, intelligence, and humanity, have really fled from the bosoms of medical men and medical societies, the presence, as "mute spectators", of Mr. Colam and his companions would be a very insufficient remedy; of their qualifications as reporters on such a subject, it is unnecessary to speak.

RECENT URBAN MORTALITY.

DURING last week, 5,889 births, and 3,896 deaths, were registered in London and twenty other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1,000 persons living. The rate was 21 in Edinburgh, 32 in Glasgow, and 31 in Dublin. Of the eighteen largest English towns, Bristol had the lowest death-rate of 20 per 1,000; the rate was 30 per 1,000 in Salford, in Wolverhampton 31, Oldham 32, Manchester, 33, Birmingham, 34, and Nottingham, 35. The deaths from zymotic diseases were 5.8 in Birmingham, where scarlet fever and whooping-cough caused 28 deaths; and 7.4 in Hull, where 16 deaths were due to scarlet fever. In London, 2,585 births, and 1,552 deaths, were registered; the former were 68 above, the latter, 109 below the average. The death-rate was 24. The seven principal zymotic diseases caused 144 deaths, which were as many as 112 below the average; the number from each disease being also below the average. The fatal prevalence of scarlet fever continues to decline, and the Asylum District Small-pox Hospital at Homerton, which has recently been used solely for scarlet fever patients, is now empty; the two District Fever Hospitals containing only 116 cases on the 6th instant. The deaths referred to diseases of the respiratory organs, which in the five preceding weeks had steadily declined from 897 to 409, rose last week to 429, and exceeded the weekly average by 28. In outer London, the death-rate from all causes, and for the seven principal zymotic diseases, was 19.2 and 1.8 per 1,000 respectively, against 23.5 and 2.2 in inner London. The mean temperature of the air during the week, at Greenwich, was 36 deg., or 2.8 deg. below the average. Rain fell on Saturday to the amount of 0.4 of an inch.

PROFESSOR PARKER'S LECTURES.

PROFESSOR PARKER will commence his course of eighteen lectures on the structure and development of the Skull, on Monday next, in the theatre of the Royal College of Surgeons. The following is his programme: 1. Introductory; 2. Skull of Lancelet; 3. Skull of Menobranchius; 4. Skull of Frogs and Toads; 5. Skull of Snakes and Lizards; 6. Skull of Turtles and Crocodiles; 7. Skull of Birds (*Ratitæ*); 8. Skull of Birds (*Carinatae*: 1. Schizognathæ); 9. Skull of Birds (*Carinatae*: 2. Desmognathæ); 10. Skull of Birds (*Carinatae*: 3. Egithognathæ); 11. Skull of Birds (*Carinatae*: 4. Saurognathæ); 12, 13, 14. Skull of Pig; 15, 16. Skull of other Mammalia Placentalia; 17. Skull of Mammalia non Placentalia; 18. Summary and Conclusion.

A CASE FOR MEDICAL LEGISLATION.

THE *Newcastle Daily Chronicle*, of the 30th ult., reports a case which ought not to pass without notice. On the 30th of December, 1874, at Spennymoor, near Durham, a middle-aged man, named William Thompson, met with a compound fracture of his right leg in consequence of the falling upon it of a part of the machinery at a colliery. He was seen by Mr. Heffernan without delay, the fracture was set, and the leg put up in splints. In the evening, he was again visited by Mr. Heffernan, and all was going on as well as could be expected. Next day, in Mr. Heffernan's absence, the patient was seen by his assistant, who found the bones displaced. He telegraphed for instructions to Mr. Heffernan, and was desired to ask Mr. Wagstaff of Byers Green to see the case with him. When that gentleman arrived, the patient's friends refused to allow him to see the limb, the patient having expressed a wish that another person should look to his broken leg, while they might, if they liked, treat his body. Upon this, Mr. Wagstaff and Mr. Heffernan's assistant left, and saw the patient no more. The person

who had been called in to supersede them was a Mr. Robert Curry master mason and bone-setter. He said that mortification was beginning in the leg, and, as the patient was in a very bad state, he advised that a doctor should be sent for "to attend to the body". Accordingly, "Dr." Thompson of Tudhoe Grange was called in. He is a doctor of medicine of the Eclectic Medical College, Pennsylvania. He is not on the *English Register*, and does not purport to be. "He was asked to prescribe for the body, in order to strengthen the system." He did not look at the leg, as he was told that Mr. Curry had set it. He attended the patient each day till January 20th, on which day the man died. "Dr." Thompson gave it as his opinion that "the cause of death was hæmorrhage. The bleeding arose from a rupture of one of the tibial arteries. He saw the tibial bones projecting, and called Mr. Curry's attention to them". An inquest was held on the 29th ult., when the particulars that we have mentioned came to light. The verdict of the jury cannot be considered at all satisfactory. They simply decided "that deceased had his leg broken by the falling of the shell-board of a drum, and that death resulted from hæmorrhage". But no effort appears to have been made to arrest the hæmorrhage. Bleeding after a compound fracture is a common enough case, and every surgeon knows how to deal with it. To allow the patient to die without making vigorous efforts to stop the flow of blood is highly culpable. But here no effort of any sort appears to have been made. Probably the bone-setter and the Pennsylvanian doctor were alike ignorant of the rules which should have guided them in such an emergency; and to their ignorance the patient was sacrificed. Mr. Brignal, solicitor, of Durham, who represented Mr. Heffernan at the inquest, did good service by trying to show the character of "Dr." Thompson's qualifications. But it is evident that, notwithstanding the doubtful character of his diploma, he has a considerable hold on the people of the district. When a doubt was expressed as to the extent of his experience, he answered: "You only just have to take a survey round Spennymoor, and you'll soon find out." And, again, "If I have any illegal standing in England, why don't they prosecute me at law?" Why, indeed! Simply because the Medical Act is not so stringent as is desirable in the public interest. There are many parts of the country, especially in the mining and manufacturing districts, where the ignorant people are liable to fall into the hands of non-qualified practitioners. It is high time that we should have an amended Medical Act.

GILCHRIST LECTURES AT LEEDS.

DR. W. B. CARPENTER, F.R.S., gave the first lecture of the Gilchrist Educational Course on Friday, February 5th, on Ocean Circulation, and its Influence on Climate and Animal Life. The Chairman, Mr. J. I. Ikin, President of the Leeds Philosophical and Literary Society, delivered the following introductory remarks.

"I am much obliged to the Executive Committee for inviting me to take the chair on the present occasion; and it gives me sincere pleasure to do so, especially as a natural philosopher, physiologist, and anatomist of such eminence as Dr. Carpenter is about to lecture. The purport of the Gilchrist Educational Trust has been, I believe, explained in this hall on a former occasion; therefore I will not detain you on the subject, except to refer you to the prospectus of the lectures about to be delivered. The course is a highly interesting one, and cannot fail to be attractive and instructive; and I trust its value will be adequately appreciated by those for whose special instruction it is intended. The Gilchrist trustees are conferring an educational boon of no light character on the inhabitants of Leeds, and the same advantages are to be extended elsewhere. The present course is, I believe, only the second that has been given; and I trust it will be appreciated, as was the first in this town last year. Perhaps I may be allowed to state that to myself, as a member of the medical profession, and formerly a lecturer on Anatomy and Physiology in the Leeds Medical School, it affords me peculiar pleasure to have this opportunity of bearing my public testimony to the debt of gratitude due from the medical profession, as well from physiologists and naturalists and scientific men generally, to the untiring researches and lucid observations of Dr. Carpenter. I am not going to flatter or use fulsome language to my old fellow-student, as I know this would be as distasteful to him as it is foreign to my own disposition; but it does so happen I am in a position, from my own pur-

suits, to speak with confidence, if not intimate knowledge, regarding the scientific labours of your lecturer of to-night; and I merely state the facts to you. Such an example as Dr. Carpenter's successful scientific career furnishes ought to stimulate the young disciples of natural science to diligent study, and induce them to seize every opportunity of availing themselves of educational advantages like those afforded by the Gilchrist Lectures, and the instruction given by this and similar institutions. Dr. Carpenter's work on the *Principles of Physiology, Human and Comparative*, and his *Manual on Physiology*, are text-books to the scientific and medical student of the utmost value and interest. For the last thirty years, he has been our leading teacher; and I do not hesitate to affirm that there is no lecturer on anatomy and physiology in the United Kingdom that has not availed himself of his works. For myself, I candidly admit, his treatises, along with those of our mutual preceptors, Professors Sharpey and Quain, were of the greatest use, and laid the foundation of any physiological knowledge I ever attained. At the present day, no student, with the repeated revisions, new editions, and additions, that he has made to his works, can possess more instructive guides. But, as most of you may know, or ought to know, his scientific labours have not been confined to physiology. His work on the *Microscope and its Revelations* is one of the best books on the subject; and, to show how his foresight, or rather foreknowledge, has been displayed, many years ago, when minute structural and microscopic anatomy was in its infancy, Dr. Carpenter took the trouble to visit the leading provincial medical schools throughout England, in order to demonstrate to the various lecturers and students the exact structure and functions of the various minute textures of the human body, and the composition of the blood and other elementary fluids. His paper on Vital and Physical Forces in the *Philosophical Transactions* appeared in 1850. He was early enrolled a Member of the Royal Society (about 1840), and contributed papers on the Foraminifera, and a number of valuable articles in the *Cyclopaedia of Anatomy and Physiology*; viz., Nutrition, Secretion, Sleep, Smell, Taste, Touch, Varieties of Mankind, etc.; again, in the *Philosophical Transactions*, a paper on the Structure and Development of *Antedon Rosaceus*; and later still, in the same renowned publication, reports on Deep-Sea Researches, and on his present subject, Ocean Circulation, and its Influence on Climate. His address when President of the British Association for the Advancement of Science, and his numerous papers and speeches before that learned body, have rendered him one of our greatest living authorities on most branches of natural science; and he has had conferred upon him numerous foreign distinctions of a learned character; so that, when you hear him, you hear an authority on the subject on which he treats, and I congratulate you and the intelligent classes of Leeds that you have an opportunity afforded that it would be absolute folly to miss. One further remark I cannot refrain from making; that is, the happy, clear, and interesting style he has of communicating knowledge, and of explaining many hitherto ill-understood and wonderful natural phenomena. Dr. Carpenter has had large and varied opportunities of observing and recording the secrets of Nature. I must just refer to the prospectus, and will then call upon Dr. Carpenter to favour us with the first Gilchrist Lecture of the second session in Leeds."

MANCHESTER MEDICAL SOCIETY.

THE annual meeting of the Manchester Medical Society was held on January 13th, and the following are the office-bearers for 1875:—*President*: Dr. Morgan. *Vice-Presidents*: Dr. Borchardt; Dr. Lloyd Roberts; Dr. Ransome; Mr. Winsor. *Secretary*: Mr. Walter Whitehead. *Librarian*: Mr. Cullingworth. *Treasurer*: Dr. Thorburn. *Committee*: Dr. Bird; Dr. Dreschfeld; Mr. Ewart; Mr. Galt; Dr. Glascott; Dr. Hardie; Mr. Jones; Mr. Knowles; Dr. Leech; Dr. Little; Mr. Lund; Dr. W. Roberts. *Auditors*: Mr. Coathupe; Mr. Mann.

THE LADIES' SANITARY ASSOCIATION.

THE Ladies' Sanitary Association, 22, Berners Street, Oxford Street, has just issued a tract, entitled "The Doctor's Bill", which is intended to recommend Provident Dispensaries as the best means of supplying the medical wants of the working classes. It is cast in the form of a dialogue, and brings out the main points of the provident system in a way which is likely to make them intelligible to the humbler classes, both in towns and villages. Those who are setting on foot provident medical institutions, and those who are anxious to give a wider scope to such as already exist, will probably find this little tract very useful for distribution.

FATAL HÆMORRHAGE FROM WOUND OF THE PALMAR ARCH.

AN old man, sixty years of age, was recently brought to the Middlesex Hospital, quite dead and much blanched. His friends stated that he had been sitting with them all the evening in his usual health, when he had occasion to go into the back yard; after some time, as he did not return, some of the family went to look for him, and found him lying dead on the ground in a pool of blood. The only injury he had received was a cut, scarcely three-quarters of an inch long, on the palm of one hand, at the base of the little and ring fingers; the arteries to the contiguous sides of these fingers had been partially divided close to their origin from the superficial palmar arch. The old man appears to have stumbled in the dark, and, falling forward on his hands, the cut was inflicted by a piece of a broken bottle.

TRANSPORT OF THE SICK AND WOUNDED.

DR. RUSSELL, who has written the Report upon Fire-arms, Appliances of War, etc., shown in the Vienna Exhibition, gives a description of a French military hospital railway train, constructed on the plan of Baron Mundy, at the cost of the Société de Secours aux Blessés. The train consists of eight waggons, which are fitted up, one for the surgeons, one for cooking, one for provisions, one for hospital stores, and four for the sick and wounded. The report goes on to state that it is difficult to conceive anything more ingenious and perfect than the way in which these carriages are fitted. This is especially the case with the surgeons' carriage. It has four compartments, each with an arm-chair, which can be converted into a bed, a washing-stand, reading-lamp, writing-desk, chair, etc. The waggon is warmed by a stove, and there is every convenience within it, so that the inmates need not leave it for a moment. All the waggons are well ventilated and protected against dust and rain. The surgeon can pass from end to end of the train while it is in motion. In each carriage for the patients there are ten beds, and conveniences easy of access but outside the carriage. Litter or common bedsteads can be placed in the carriage, which can be cleaned without disturbing the patients. In peace time, the carriage can be used as a common goods-van. On war breaking out, the van can carry troops or provisions to the front; and, after discharging these, can be quickly and easily fitted up as an ambulance. The Russians contributed an ambulance for four men, two lying on the floor and two slung above, to which was awarded a medal of merit. An ambulance-tent, on Col. Leschine's system, also found much favour with the commissioners. Instead of canvas or jute, Col. Leschine uses laths strung together, overlapping each other like Venetian blinds. The ridge is of canvas. The frames are of iron, four in number. Its merits are as follows: the soldiers themselves can construct the material; it can be rolled up, and occupies little space; it is twice as durable as linen or canvas; pine, the cheapest, lightest, and least subject to atmospheric influences of ordinary woods, can be used. It can be packed immediately afterwards. The construction is simple, and the tent can be easily put together, taken to pieces, and transported.

THE PHARMACY OF 1874.

THE *Chemist and Druggist* briefly enumerates some of the principal pharmaceutical novelties of the past year, as follows. Boldo is probably the latest candidate for notice. The leaves are used on account of the aromatic oil they contain. The alkaloid discovered has been called boldine by Claude Verne and M. Bourgoïn, the joint discoverers. The tree is indigenous to the New World; the leaves are covered on their surface with small glands. In South America, the plant is a popular remedy against syphilis and diseases of the liver. The essential oil is contained in cells, which are met with in nearly every part. The oil-vessels are perfectly spherical and of large diameter. The volatile oil is the most abundant product, as much as two per cent. having been frequently obtained, and is a mixture of various bodies. The preparations used are (1) alcoholic extract; (2) aqueous extract; (3) essential oil; (4) tincture; (5) wine made with Madeira; (6) syrup; (7) elixir. The leaves and flower-stems are alone employed. The

dose of the wine is one tablespoonful to a wineglassful once or twice a-day. Vomiting is induced by too large doses. Professor Kolbe has succeeded in producing artificial salicylic acid from carbolic acid by the joint action of carbonic anhydride and sodium. Its antiseptic and physiological properties were found to be remarkable. 1. Fresh meat rubbed with the acid kept for a week, though exposed to the air. Many similar experiments were successful. 2. Solution of amygdalin mixed with emulsion of sweet almonds developed no smell of bitter almonds if some salicylic acid were added. 3. Salicylic acid added to beer in the proportion of 1 to 1000 prevented the formation of fungoid growth. 4. Fresh urine was divided into two portions, to one of which salicylic acid was added, while the other was left untouched. After three days the latter was putrid; and the former, protected by the acid, was still clear and free from ammoniacal odour. Dr. Tilbury Fox has explained his views of what should be the physical characters of calamine powder, distinct from "the old-fashioned dirty red gritty powder of the shops". The following should be its properties; colour—very pale salmon, or pale flesh-colour; texture—an impalpable powder; constitution—genuine. It is prepared only by incineration, levigation, and subsidence. Mr. J. Morris Broad suggests the use of equal parts by measure of glycerin and water instead of syrup, in the manufacture of the syrups of the phosphates. Mr. H. C. Baildon of Edinburgh claims an official place for *rhamnus frangula* in pharmacy. It possesses admirable laxative qualities, without the griping effects of senna. It appears, according to Mr. Giles, to have tonic and aromatic qualities which stimulate the muscular action of the bowels, as distinguished from the cathartic influence produced by irritating purgatives. It has answered well in counteracting habitual constipation. The bark of the younger trunks and of the larger branches of the indigenous shrub are gathered in the spring. This kind should alone be used, as the bark taken from the thick part of the trunk is entirely different. That obtained from the quill-bark yields a decoction pleasant to the taste, and with a slight flavour of almond, or prussic acid. Half an ounce is directed to be added to a pint of water, and the decoction boiled down to half a pint. Three tablespoonfuls are a dose. Jaborandi has been tried at the Hospital Beaujon in Paris. Dr. S. Coutinho of Pernambuco is the discoverer, and he has handed it over to Professor Gubler to make experiments. An infusion of leaves and twigs in warm water (dose half an ounce) produces violent perspiration and remarkably increased salivation.

SCOTLAND.

THE CONTAGIOUS DISEASES ACTS.

A MEETING of those favourable to the total repeal of the Contagious Diseases Acts was recently held in Edinburgh, to hear an address by the Right Hon. J. Stansfeld; which, however, met with but very partial success, the hall being not more than half filled. The majority of the audience were females. The lecturer disposed of the subject in the usual way, asserting that, "in his opinion, the Acts in question could not fail to be hygienically a mistake, as he could not believe that any statutes which transgressed the higher moral law could, in the long run, promote physical health"; and a good deal more to the same purpose.

HOSPITAL FOR INCURABLES, EDINBURGH.

THE Committee of Managers of the fund for a Hospital for Incurables, in behalf of which vigorous efforts have lately been made, have lost no time in making use of the funds collected at the recently held great bazaar and elsewhere. A temporary building has been found, and is to be opened, under the name of the Edinburgh Hospital for Incurables, for the reception of patients, on February 15th. It consists of a house or houses in Salisbury Road, a pleasant locality in the southern suburbs of the city, and is expected to accommodate between twenty and thirty persons. A number of things left unsold at the bazaar were disposed of last week, and the whole amount realised from that source was increased to £5,730 odd, a very handsome sum to raise

by such means; while the expenses have, it is understood, been found to be considerably less than was at first expected. Applications for admission, accompanied by the necessary medical certificates, are to be made at once by those desiring to obtain the benefits of the institution.

THE STATUES OF SIMPSON AND LIVINGSTONE.

THE question of suitable sites for the statues of Sir James Simpson and Livingstone, which are shortly to be set up in some public place, came under the consideration of the Edinburgh Town Council at its last meeting. As regards the Simpson statue, a majority were opposed to the proposal to place it in St. Andrew's Square, and the general feeling was in favour of the site in the East Princes Street Gardens, near the Scott monument, and to its western side. The Livingstone statue, it was at first suggested, should be placed where the four lamps now stand at the top of the Waverley Bridge; but, on further consideration, another spot in the gardens, to the east of the Scott monument, was selected as in every way more desirable.

HIGH DEATH-RATE IN KILMARNOCK.

THE town of Kilmarnock, in Ayrshire, has just achieved a most unenviable notoriety, in consequence of its most remarkable death-rate. During last month, no fewer than 104 deaths have been registered in that borough, the largest in any month since the Registration Act came into operation, showing a mortality of 52 per 1,000. The principal cause of death was scarlatina, of which there were twenty-one fatal cases, against thirty in December. Curiously enough, the number of births during the month was 109, the highest yet recorded in a month.

LEGACIES.

THE charitable and educational institutions of Edinburgh have recently come in for very handsome legacies under the will of the late Robert Marshall, of the firm of Marshall and Aitken, tailors, who died on the 19th of last month, at a very advanced age. Among other bequests, he left £500 to the Royal Infirmary, £100 to the Children's Hospital, £150 to the Royal Public Dispensary, £500 to the University to found a Marshall Bursary, £300 to the Life Boat Institution, and numerous other sums, amounting altogether to £3,650, to various missions, societies for indigent gentlewomen and governesses, the Maternity Hospital, and other charitable undertakings, of which the name in Edinburgh is legion. The residue of the estate, which, after providing for private legacies, will amount to upwards of £20,000, the trustees are directed to "dispose and apply towards the promotion of such charitable institutions or purposes, in relieving aged or indigent individuals, or in promoting of education through schools and colleges in Scotland, as they shall determine on as worthy of such aid"; the whole to be distributed in sums not exceeding £200 at any one time.

IRELAND.

At a late meeting of the Thurles Board of Guardians, the salary of Dr. Quinlan, medical officer of Borrisoleigh Dispensary, was increased by £20 *per annum*.

SCARLET fever, according to the late returns of the Registrar-General, is decreasing considerably in Dublin. In the week ending January 30th, there were only four deaths registered from that affection, and six the week preceding.

STEWART INSTITUTION FOR IMBECILES.

THE annual meeting of the friends of this charitable institution took place last week in the Molesworth Hall, Dublin, the chair being occupied by Lord James Butler. The annual report shows that the institution is making satisfactory progress, the subscriptions being increased by £146 6s. 6d., and donations were received amounting to £2,709 6s. 9d. In the latter sum is included a donation of £1,000 by the late Mr. Alexander Findlater of Dublin, and a bequest of £500 from the same gentleman. At the close of the year, there were forty-one

children in the institution; of these, fourteen were free pupils elected by the subscribers, eight paid the full cost, and nineteen paid a portion of their maintenance. As a proof of the good that kindness, proper food, medical attendance, and systematic and properly applied instruction, has on this class of people, the most wretched and pitiable that can exist, we may mention that, of these forty-one children, seven can assist themselves in a limited way, twelve are capable of learning a trade, twenty-five attend the drilling class, nine work in the garden, fifteen assist in cleaning shoes, eleven act as messengers, sixteen assist in household work, six attend the sewing class, five are instructed in arithmetic, two are learning to read, three read well, fifteen assist in dressing children, six work in the mat shop, five in the tailor's shop, twelve can speak well, and ten indistinctly. At the meeting, several articles made by the inmates, such as mats, baskets, clothing, book-markers, etc., were exhibited, and reflected great credit on the inmates, and on the medical superintendent of the institution.

BELFAST GENERAL HOSPITAL.

At a quarterly meeting of the committee of management of this institution, held on last Saturday, it was announced that Her Majesty had, on the recommendation of the Duke of Abercorn, granted a royal charter for the hospital, and which the committee expect to receive in a few weeks.

MORTALITY AFTER AMPUTATION.

At a recent meeting of the Surgical Society of Ireland, Professor Macnamara is reported to have said:

It is most remarkable that there should exist so great a contrast between the mortality after capital amputations in England and that which followed similar operations in Ireland. I have performed a great many capital amputations, and I never lost a patient; and I appeal to the experienced surgeons present whether it is not the fact that death after amputations in Ireland is the exception. In England, however, we read of the deaths being one in three or four. The Vice-President of the College, who has had a large experience, tells me he scarcely ever remembers seeing a death after amputation.

The statement is exceedingly interesting; and we may venture to ask Mr. Macnamara to favour us and his surgical brethren in England, by putting us in possession of the series of figures on which it is founded. The relatively greater mortality after operations which is experienced in the Paris hospitals, as compared with the English, was attributed by an eminent French surgeon to the fact that the English patients possessed the "chair chirurgicale"—that is, a kind of flesh which healed easily—while French patients did not. No doubt, our colleagues in Dublin will be able to give us some more satisfactory explanations than that. Mr. Callender has of late, in the lectures which we published, given the figures of his practice in St. Bartholomew's Hospital, and the methods by which he has succeeded in obtaining a rather long series of singularly favourable results after amputation. Will Mr. Macnamara and his colleagues oblige us similarly with the unbroken records of the results of series of operations in the Dublin hospitals, with a note of the methods and principles of treatment?

SCIENTIFIC GRANTS OF THE BRITISH MEDICAL ASSOCIATION.

At the last meeting of the Committee of Council of the British Medical Association, the following grants were made:—Mr. Hicks, Cambridge—Researches on Alcohol, £50; Dr. P. M. Braidwood and Mr. Francis Vacher, Birkenhead—The Life History of Contagion, £15; Dr. R. Caton, Liverpool—The Natural Electric Currents of the Brain, £20; Dr. J. M. Fothergill, London—The Effect of Certain Agents upon the Circulation, £10; Dr. McKendrick and Mr. James Dewar, Edinburgh—Physiological Action of Chinoline and Pyridine Compounds, £25; Dr. Mahomed, London—The Pathology of Albuminuria, £20; Dr. Munro, Cupar Fife—An Antidote for Chloroform, £5; Dr. W. H. Spencer, Clifton, Bristol—The Action of Uranium Salts in Diabetes, £20. The grants in all amount to £165. Certain other applications have been referred to a Subcommittee, with power to appropriate the balance of the sum of £200 voted, if the particulars furnished by the applicants are satisfactory.

MEDICAL ADVERTISING.

WE have not received any letters for publication on the article published last week on this important subject; but, from the indications contained in one or two private letters which lie before us, we conclude that the purport of the article has been by some readers misapprehended. It does not appear to us easily open to such misapprehension. Nevertheless, we desire to point out that the object expressly stated was not to imply blame of individuals, but, on the contrary, to point out that, without their knowledge, and probably under circumstances of which they would all disapprove, public use has been made of their names in a mode of advertising which is held to be professionally objectionable. We asked for some expression of their disapproval of that mode of using their names, because, without that expression, it did not, and does not, appear clear that such advertising would not be repeated, if not with the use of their names, still with the use of the names of others of similar standing. Until such public expression of disapproval in some form is made, it seems evident that there is nothing to prevent a repetition of the circumstances to which we called attention. The fact that individuals disapprove of the use which has been made of their names, affords only the more emphatic condemnation of the system by which their names can be so used; it is the propriety of the system only which we question. That was, we thought, very apparent in the text of the article.

Its object, however, was not confined to blaming the system of advertising in newspapers medical articles and books intended only for professional education; it extended to the provision of a remedy by the discussion and, if approved, the adoption of a general rule, that in future no medical books and articles be advertised in daily papers, or placarded in places of public resort. That, as we stated, is the prevalent rule on the Continent, and it is one which might, it was suggested, with great advantage be adopted here. The fact that such advertisements have recently been employed for trade purposes, parading the names of eminent men without their knowledge, seems to us to give point to the requirement. The intimation from those gentlemen that they do disapprove of the use so made of their names would undoubtedly assist in preventing the repetition of it, and would help to lay the basis of a future agreement on the subject; but we by no means imply that they are bound to give any public expression of their approval or disapproval of the use made of their names, or of the propositions which we have based upon it. If they do so, it will, we think, assist in the final solution of the question, What shall the rule be in future as to the advertisement of medical books and articles by publishers and others? Shall they continue to be advertised in newspapers, and placarded at railway stations, or not? If they are not disposed to express any public opinion on the subject, we shall still continue to endeavour, with the general assistance of the profession, to arrive at some more satisfactory conclusion than is afforded by the existing state of things. We feel sure that, in any case, we shall have their best wishes. The question is entirely one of principle, and we repeat that we have no intention to treat it, directly or indirectly, absolutely or inferentially, except as one of principle.

SPECIAL CORRESPONDENCE.

BIRMINGHAM.

[FROM OUR OWN CORRESPONDENT.]

Founding of the Birmingham Medical Institute.—Health of the Town.—Sanitary Teaching.—Disinfection.—The Board of Guardians.—The Lying-in Charity Report.—The Children's Hospital Annual Meeting.

ONE of the most important chapters in local medical history was commenced last week at a meeting of the profession called to form a Medical Institute. For many years, our great want has been a *locus in quo*—a professional public building—and with it a worthy reference-library. The late Dr. Evans left, in the hands of trustees, a large sum of money which had been offered to him in the form of a testimonial, and which his own liberality raised to £1,000, to be applied towards a medical library. More recently, the Rev. Charles Ingleby, son of an eminent local practitioner, having left a large sum of money to be divided amongst the institutions of Birmingham, the Evans' trustees with wise forethought incorporated themselves under the Companies Act, and made application for a donation to carry out the objects of their Association; and they received, through Mr. Wragge, the liberal offer of £5,000 under certain conditions. These conditions required the raising of a separate fund for building and other purposes, the Ingleby Fund to be

then available for maintenance. The number of trustees named by Dr. Evans was seven; and these, with six other gentlemen, formed the original members of the Institute, as follows: Dr. Fletcher, Dr. Heslop, Dr. Russell, Dr. Wade, Dr. Fleming, Mr. Crompton, Mr. Baker, Mr. Berry, Mr. Bindley, Mr. Middlemore, Mr. F. Jordan, Mr. T. Evans, and Mr. G. H. Evans (Honorary Secretary). These names were appended to the circular calling the meeting, the object of which was to place the project on a broad and liberal basis, and to secure the support and co-operation of the whole body of the profession. The chair was taken by Dr. Fletcher, who moved the following resolution, which was seconded by Mr. F. Jordan, "That this meeting is of opinion that the Birmingham Medical Institute is well adapted to meet a most pressing want, and to prove of the greatest value and importance, as well to the members of the medical profession in Birmingham and the district as to the public, and pledges itself to use every effort to promote the success of the undertaking." A resolution naming one guinea as the annual subscription was proposed by Dr. Johnston, seconded by Dr. Harrison, and carried; and a further resolution, naming a committee to act with the original committee in the election of members, was proposed by Mr. Gangee, and seconded by Mr. Manley. Dr. Heslop having taken the chair, cordial thanks were voted to Dr. Fletcher, and to Mr. T. Evans, who had given able legal advice. The amount of money already subscribed towards the building fund amounts to about £2,000, including no fewer than twelve subscriptions of £100 each from members of the profession, and seven of £50. Gentlemen outside the profession have also subscribed liberally.

The death-rate of the town is exceptionally high. Scarlatina has been lately the most fatal zymotic, then variola and pertussis; erysipelas has been prevalent in various quarters, and rather bad in the hospitals.

The Sanitary Conference has been fully reported in your columns. Knowledge in the same direction has been further promoted by a donation (anonymous) of £3,000 to Salter Training College, to found a Laws of Health Teachers' Trust, providing for the delivery of lectures to future teachers, with money prizes for proficiency, the prize-winners to continue to teach the subject to their own classes. Sanitary lectures are also being delivered. Dr. Corfield has given a popular lecture on fever; Dr. Hill on healthy homes; and Mrs. Bracey and Miss Kenrick have continued their excellent teachings to women. Handbills also are circulated by the authorities, and a sanitary "census" has been completed under the following headings: Number of houses in each ward; number of persons in family; number of lodgers; houses with through ventilation (front and back door); houses with windows at the top (?); water-supply, whether from tap, pump, or *nil*.

The medical officer of health has been instructed to visit Nottingham and Manchester, to inspect their disinfecting apparatus. The "Ransom" apparatus, as in use at Nottingham, has been decided upon. There is at present no public disinfecting oven, but there is a good one in use at the Queen's Hospital.

We regret that Mr. John Clay should have been obliged to resign the chairmanship of the Dispensary Committee of the Board of Guardians, and not only that office, but the office of Guardian also. We consider this a public loss; at the same time, we confess we do not see how Mr. Clay could continue to work with such men as are amongst the present members of the Board. The parish medical officers applied for an increase of salary on the grounds of increased cost of living, increased work, and change in its character involving loss. Mr. Clay ably supported this very desirable motion, and, on its rude negation, resigned office.

At the annual meeting of the Birmingham Lying-in Charity, statistics were adduced showing the year's mortality as 1 in 252; average of seven years, 1 in 461. The carefully prepared and favourable statistics of last year had elicited the warm approval of Miss Nightingale; and, *à propos* of them, she had quoted the following remark of a medical man unnamed—"Although accoucheurs winced under castigation, they have mended their ways; so there will be smaller mortality in time to come." The chairman of the charity (Mr. Goodman) naturally compared with some satisfaction the above averages to the numbers lately given by Dr. M. Duncan (1 in 120), and stated that their own statistics were equally calculated to include thirty days after confinement. The chairman of the meeting (Mr. Chamberlain) observed that the very satisfactory statistics perfectly justified the steps which were taken amidst some opposition several years ago, to do away with an in-patient department, and give aid only, as at present, to women at home. One of the officers of the charity (Mr. Tait) had, however, written to the local paper to take exception to the remark quoted from Miss Nightingale's letter, and also to the conclusions drawn from the statistics; laying stress upon the fact that unmarried women are excluded from attendance, and that bad cases are transferred to the general dispensary.

At the annual meeting of the Children's Hospital, it was reported that the Committee had reduced the number of beds from fifty-eight to forty-four, in order to prevent crowding; also, that the fever-wards had been closed for three months' disinfection. The building of extra waiting-rooms and the appointment of an additional medical officer, were suggested. The President, the Marquis of Hertford, in the course of his Address, observed, "That he had been over kindred institutions, such as the Children's Hospital in London, and others, and he could honestly say that it was impossible for matters to be better arranged than they were in the Birmingham Children's Hospital." At a meeting of the Committee of Election held to-day, Dr. Flamank Marshall was elected extra acting physician to the hospital.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 9TH, 1875.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

Experiments on Animals.—The following correspondence was read by Dr. Symes Thompson, one of the Secretaries.

1. "Royal Society for the Prevention of Cruelty to Animals, 29th Jan., 1875.

"Sir,—On Monday last, a memorial signed by many distinguished persons, was presented by an influential deputation to the Committee of this Society, supported by papers, which allege that experiments on living animals are frequently, if not regularly, performed at the various schools of medicine and physiology, hospitals, and other similar institutions of London, for the purpose of discovery, of demonstration, or of illustration.

"A special Committee has been appointed to deliberate on the statements and proposals of the said memorial and papers. I am desired by such Committee to ask you to be good enough to do them the great favour of permitting me, with two other gentlemen, to be present as mute spectators on the occasions alluded to when operations on living animals are appointed to be performed at your institution, in order that we may report the proceedings to them.

"The Committee trust you will appreciate the nature of this application, which they think it their duty to make, instead of resorting to other usual modes of acquiring information.—I have the honour to be, Sir, your obedient servant,

"JOHN COLAM, Secretary.

"To E. S. Thompson, Esq., M.D., Hon. Sec. Royal Medical and Chirurgical Society."

2. "Royal Medical and Chirurgical Society, 53, Berners Street, W., Feb. 9th, 1875.

"Sir,—We are directed by the Council of the Royal Medical and Chirurgical Society to inform you, that the Society is not at present engaged in contemplating any experiment involving vivisections.

"We are requested also to add, that if the Society should undertake any further scientific investigations, rendering such processes necessary, they would certainly decline the presence or interference of any unqualified witnesses.—We are, Sir, faithfully yours,

"E. SYMES THOMPSON, M.D., Hon. Sec., Roy. Med.

"J. COOPER FORSTER, Hon. Sec., and Chir. Society.

"To the Secretary of the Society for the Prevention of Cruelty to Animals."

No discussion took place; but the reading of the Council's reply was received with marks of approbation by the members present.

Hypospadias and Epispadias.—Mr. JOHN WOOD exhibited some cases of hypospadias and epispadias, on which he had operated. Two of the cases of hypospadias were boys, who had been unable to pass urine in the erect position, but were obliged to crouch down. The stream passed backwards. Having previously, in other cases, tried various plans with unsatisfactory results, he adopted in these cases a plan which he had found successful in two other patients some time ago. It consisted in making a hole in the prepuce, through which the glans was made to protrude—the operation being somewhat the reverse of that of Nélaton for epispadias. At first, he did not realise the difficulty of properly adjusting the parts; but he succeeded by making a broad flap and turning the skin inwards to the urethra. The prepuce was utilised for the formation of a channel for the urine. In one of the cases, there was a *cul-de-sac* apparently representing the fossa navicularis, with the urethral opening behind it. This he slit up so as to form a continuous channel. In the case of epispadias, there was want of retention of urine; but this defect had been quite overcome by first operating by Nélaton's method, and then performing two subsequent operations for completing the channel.

ON THE TREATMENT OF FISTULOUS OPENINGS BY DILATATION. BY WM. MURRAY, M.D., OF NEWCASTLE-ON-TYNE.

THE author had been induced to try the effect of dilating sinuses by tangle-tents, because of the contraction which sometimes follows their use, on the principle that the lymph which is effused by the inflammation of rapidly dilated tissues will sometimes close a sinus by its subsequent contraction. The treatment was tried in a case of fecal fistula at the umbilicus; and, after two or three dilatations, a barrier of lymph was effused which, by its contraction, closed the opening. In a case of fistula in the cheek, the same success was rapidly obtained. In a curious case of fistula of the urethra, the canal was closed after one or two dilations, other surgical treatment having completely failed. In ordinary sinuses connected with strumous glands, good results were obtained by dilating, so as to let out curdy matters, and by setting up adhesive inflammation. The author asked surgeons to test the treatment in other cases, and suggested the use of tents for opening up sinuses connected with diseased bones and foreign bodies. By so doing, the parts might be explored, and the offending substance might be removed without cutting.

Mr. JOHN WOOD would not detract from the merit of originality in the paper; but the proposal to dilate a sinus leading to dead bone was carried out long ago by Nélaton, by means of a piece of gentian-root, in Garibaldi's case. *A priori*, the plan described by Dr. Murray would scarcely recommend itself to surgeons, as its principle was to dilate an opening in order to close it. The plan had been followed in Wutzer's operation for the radical cure of hernia, and had been found to fail. He would not, however, absolutely condemn it without further evidence.

ON THE DIAGNOSTIC VALUE OF THE ILIO-FEMORAL TRIANGLE IN CASES OF INJURY TO THE HIP, MORE PARTICULARLY OF IMPACTED FRACTURE. BY THOMAS BRYANT, F.R.C.S.

THE triangle which the author described as the ilio-femoral, was formed between the ilium and the great trochanter of the femur. One side of it, AB, was drawn from the anterior superior spinous process of the ilium, A, to the top of the trochanter major, B; the second, AC, was drawn from the anterior superior spinous process of the ilium directly downwards to the horizontal plane of the recumbent body; and the third, CB, the base of the triangle, was drawn at right angles to AC, and fell upon the line AB when it touched the great trochanter. To this line the author's observations referred. He said that the line AB corresponded in the normal condition of the hip-joint to Nélaton's test line for dislocation of the head of the thigh-bone backwards, and he regarded the line of the triangle described (CB) to be the test-line for fractures or shortening of the neck of the thigh-bone. He stated that after repeated proofs he could confidently assert that, whilst in a healthy subject the ilio-femoral triangles of the two sides were exactly similar in all cases of injury to the hips, in which shortening of the neck of the thigh-bone existed, the amount of shortening could readily and accurately be made out on comparing the bases of the triangles of the two sides. In impacted fracture, where on the sound side the base of the triangle would, in the adult, measure its average normal length of two and a half inches, on the affected or injured side, it would measure from half an inch to more than one inch less. These measurements were taken with the patient in the horizontal position, the pelvis straight, and the two femora parallel. The author illustrated his paper by quoting half a dozen cases of impacted fracture, in which by the test-line the shortening in the neck of the thigh-bone was readily made out; and concluded by pointing out the value of such simple and certain means of making out whether any shortening of the neck of the thigh-bone exists after an injury, preventing any undue manipulation of the hip-joint in cases of impacted fracture or other obscure injuries to the joint. He then passed on to point out how fallacies in the test might be met with; but, as they were quite exceptional in practice, he thought that they could in no way tend to diminish the value of the test line as a means of diagnosis in hip-joint injuries. The paper was illustrated with drawings and a diagram.

Mr. G. POLLOCK asked whether Mr. Bryant did not find equally good results from the old plan of measuring from the anterior superior spinous process to the patella. The plan proposed was, however, so mathematically correct that it might be an useful aid in diagnosis.—Mr. THOMAS SMITH said that it had to be proved that the plan of measurement described by Mr. Bryant could be applied to all bodies. It would be difficult, in a corpulent elderly person, to estimate the position of the trochanter. He had recently been engaged in making measurements on the dead subject; and had found that accuracy could be obtained only by driving a bradawl into the bone. He would prefer the measurement from the anterior superior spine of the ilium (which is readily recognisable) to the external malleolus. The line proposed to be dropped from the spine of the ilium might not be vertical; and it

might be difficult to find the position of the trochanter.—Mr. BARWELL spoke of the difficulty of obtaining a perpendicular line on a rounded surface. It was not only necessary to observe that the line AC was perpendicular, but there was a difficulty in drawing BC at a right angle to it. The measurement from the spine of the ilium to the malleolus was a great guide to diagnosis. The amount of shortening would be better determined by stretching a tape from the anterior superior spine to the great trochanter than by Mr. Bryant's lines. This plan might be applied in cases of fractures and dislocation. Not unfrequently fractures occurred in thigh-bones which were not accurately alike on both sides, as in old persons who had had rickets. All difficulties here, however, would be removed by measuring through Nelaton's line, rather than from the anterior superior spinous process of the malleolus.—Mr. JOHN WOOD recognised the importance of the measurement of the base of the triangle as recommended by Mr. Bryant; and he thought a measurement of the kind better than Nelaton's line. He measured, however, from the crest of the ilium to the trochanter; at the same time, in stout females with loose flabby tissue, he combined with it measurement according to the old plan.—Mr. MAUNIER thought that the diagnosis of impacted fracture of the neck of the thigh-bone was well established and very easy. Its signs were negative rather than positive. The limb remained still capable of some motion—which was not the case in dislocation and fracture; but a great point was that, in consequence of the bone being driven into the trochanter, the mass of bone could be felt with the fingers.—Mr. W. ADAMS thought the plan of measurement described by Mr. Bryant likely to be useful in the diagnosis of chronic disease and congenital dislocation of the hip-joint in children. He had used a somewhat similar method, by making dotted lines over the parts.—Mr. CALLENDER said that the late Mr. Stanley took great interest in measurements, especially in fractures of the thigh-bone. He used to measure between the different parts by using a flat surface—such as an ordinary prescription board—as the fixed point, in such a way as to ascertain not only the amount of shortening but of lateral depression.—Mr. BRYANT said that he would not have brought the plan before the Society unless he had been convinced of its superiority, both in thin and in fat subjects. He did not use a plumb-line, but measured with tape. The plan was especially useful in determining the shortening of bone without subjecting the patient to unnecessary manipulation.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, FEBRUARY 4TH, 1875.

W. H. BROADBENT, M.D., President, in the Chair.

Cerebral Complications of Typhoid Fever in Children.—Dr. W. H. DAY read a paper on the cerebral complications of typhoid fever in children. He said that the frequency of diseases of the nervous system in early life, and the dangers which attend their course when they occur as the sequel of disturbance in the vascular system, give them an importance which cannot be over-estimated, and invite our attention to the grave consequences that might follow a false or imperfect diagnosis. The nervous system derives its strength and vigour from a due supply of healthy blood; and, if this be in any way changed or disorganised by the fever-process, it becomes excited, depressed, or in some way unstrung. Thus it is that, independent of the febrile condition, morbid sensations, nervous prostration, and those mental phenomena of which we daily see the effect rather than the cause, are of such common occurrence. The author cited two cases of cerebral complication occurring in the course of typhoid fever, in which the *post mortem* appearances gave a perfectly healthy state of the brain and its membranes. He related two other cases in which he believed that the inflammatory process played some part in the changes that were observed in the brain—changes independent of the tubercular cachexia, and where no such deposit could be found in any organ of the body. It was impossible to enumerate any symptoms as diagnostic of the degree of cerebral congestion that might be present in any given case. The state of the brain and its membranes bore no approximate relation to the symptoms. The author considered that meningitis uncomplicated with the tubercular cachexia occurred now and then in typhoid fever, in rare and exceptional cases. Setting aside the injurious effect which the circulation of poisoned blood at an elevated temperature must have on the nervous centres, there seemed no satisfactory reason why the cerebral changes should be restricted to congestion of the vessels or simple vascularity of the membranes. The author endorsed the statement of other observers, that we cannot, in certain obscure cases, separate a form of typhoid in young children, characterised by a distinctly remittent type, from cerebral meningitis. If the symptoms be mixed up together in various degrees, the diagnosis between the two affections is

often impossible. There were few greater or more perplexing difficulties in the practice of medicine. The author commented on the dangers of hasty induction and rash conclusions, and pointed out the risk of setting down the vomiting and cerebral symptoms to the typhoid state, whilst the brain might have been slowly and imperceptibly going wrong, and was, perhaps, the primary source of trouble.—A discussion followed, in which the President, Dr. Symes Thompson, Dr. Cleveland, Mr. Cripps, Dr. Lawrence, Dr. de G. Griffith, Dr. Farquharson, and Dr. Easton, took part.

CORRESPONDENCE.

THE NEW NAVAL MEDICAL WARRANT.

SIR,—*Bis dat qui cito dat* is an adage well known and appreciated in the profession. The Naval Medical Warrant received Her Majesty's signature on the 4th, and appeared in the *Gazette* of the 6th. No time was, therefore, lost in making known its provisions. Nothing but commendation can be expressed for the very liberal manner in which it has dealt with the various matters that have received attention; and, if some disappointment is felt that the full-pay has not been readjusted, it must not be inferred that the department is ungrateful for the very many and substantial benefits it confers. Mr. Ward Hunt and his colleagues deserve the thanks of the profession, and it can now with truth and justice be stated that the medical service of the Royal Navy is one which offers advantages to the young medical officer that he will with difficulty find elsewhere. It is with a feeling of satisfaction that one can conscientiously advise our younger brethren to join. A young man now enters the service with a befitting rank, exceedingly good pay, and every requisite to make him feel that he is in the position of a gentleman. It remains entirely with himself how he will turn to proper advantage the very liberal concessions that have been made.

One word, in conclusion, as to the part played by the Association and your JOURNAL throughout the struggle. We all feel, had it not been for the powerful assistance we derived from our professional brethren, who so kindly espoused our cause and made their voice heard, we might long have remained unemancipated; and it is to be hoped that naval medical officers will never forget what is due to the British Medical Association during the eventful years 1874-75.

I am, etc., A NAVAL MEDICAL OFFICER.

* * The above is from a distinguished member of the service. We beg to thank others who have forwarded to us very warm and generous expressions of acknowledgment, on behalf of themselves and their fellows, for the zealous and successful efforts of the Parliamentary Committee of the Association and the JOURNAL in their behalf. As, however, these letters must not, by the rules of the service, be signed by their authors, we think it unnecessary to publish them, although highly appreciating their tenour.

THE ABUSE OF HOSPITALS.

SIR,—Mr. Wordsworth's suggestion, that the British Medical Association, in its corporate capacity, should be requested to consider the subject of hospital abuse, is identical with that which was made by Mr. Fairlie Clarke in your columns a few weeks ago, and which has given rise to the memorial which he and I are now promoting. That memorial you kindly published *in extenso* on the 2nd ultimo, and you have since been good enough to print the names of those who have signed it. These signatures now amount to nearly two hundred, including those of many leading members of the profession in London and the provinces. We propose to keep the list open until April, and shall be glad to receive the names of any gentlemen who wish to support the movement.

Your obedient servant,

ALFRED MEADOWS.

27, George Street, Hanover Square.

PROFESSIONAL FEES.

SIR,—If anything were wanted to prove the necessity for a British Medical Association, it would be the course taken by the Councils of the Colleges of Surgeons and Physicians with respect to the fees to which the Fellows and Members are entitled, or which they may justly claim, for professional services to the public.

Nothing like authority can be quoted by any Fellow of any College to prove the justice of a disputed claim, or even to inform a professional brother, or an interested patient, what is considered to be a fair and proper, or usual, fee for any ordinary or extraordinary service. It has come to be generally known that the fee of a consulting physician or surgeon in London is one guinea for a visit, two guineas for a consultation with another practitioner; and that journeys to a distance are calculated at one guinea a mile by road, or two-thirds of a guinea a mile by railway. But no one thanks the Colleges, or any College Council, for this. It was an arrangement made by a few leading men—a small association—and ratified by general assent of their contemporaries and successors. But even now it is only partially known to the public, not very perfectly understood by country practitioners, and, in any case of doubt or dispute, is quite unsupported by any official authority. It is a mere matter of custom.

The Colleges, or the councils elected to manage the affairs of the Colleges, have hitherto treated the question with sublime indifference; have left those who elect them without help or guidance; and it is to our Association alone, and to its Branches, that our members can look for any aid in case of doubt or difficulty. Happily, all the machinery is prepared by our constitution for the settlement of this or any other question of medical ethics or etiquette. London, Edinburgh, and Dublin are fully represented in the Association, while in the provinces there are district Branches sufficiently near to avoid any error in the appreciation of local conditions. The Shropshire Ethical Branch has issued a "tariff" for consideration, and for the guidance of general practitioners, as distinguished from consultants; and, as the best mode of arriving at a more general acceptance of some such scale of fees for general practitioners, and a more uniform scale for consulting physicians and operating surgeons, the Branch sent copies of the tariff to the presidents of the Colleges in England, Scotland, and Ireland, for submission to the respective councils. The result is, that nothing can be expected of the Colleges, and that we must trust to ourselves.

It is certainly high time that each of our Branches and the United Association should enter upon this important question. If it be so difficult that the College councils are anxious to shirk responsibility, so much the stronger is the reason why individual members should not be left without guidance to their own resources. If it be impossible to construct, as all must allow, a *uniform* scale of fees for all members of a College, for consulting and family practitioners, for town and country, for seniors and juniors, and for rich and poor patients; if it be also very difficult to define how variations in any scale of fees can be admitted with perfect justice,—the answer is, that difficulties are better met by conjoint than by individual action. No practitioner can be, or ought to be, indifferent to fair and just reward for honourable service; and it would be extremely convenient if he could point to some authoritative schedule to meet any question of excessive or inconsistent demand upon a patient, or any attempt to lower the standard of professional remuneration in any town or district.

Beginning with London, and with consulting physicians and operating surgeons, here it is certainly high time that several modifications of time-honoured custom which have of late years been more or less generally accepted should be fully considered and made known. A double fee for first visits of patients at the residence of the consultant; for any visit out of his own house, or beyond some fixed distance from it; for visits within a suburban radius of ten miles, as distinguished from larger railway journeys; for time detained in the country, or at a patient's house, or in law courts,—are all subjects equally important both to surgeon and to physician. To the surgeon, the fees for operations, for those who administer anaesthetics and otherwise assist at the operation, and for the attendance after operation, are now left very much to the judgment of individuals. There is a sort of loose understanding that, for the great capital operations attended with risk to life (ovariotomy, lithotomy, the greater amputations and resections), one hundred guineas is a proper average fee; while half that fee is sufficient for herniotomy, removal of a breast, ligature of an artery, or a minor amputation. Ophthalmic surgeons have made one hundred guineas the usual fee for extracting a cataract, fifty for iridectomy, twenty-five for strabismus, and so on, with more or less variation, according to the standing of the surgeon and the means of the patient. But there is

nothing like any general accord as to the fees for assistants, or for attendance after operation. The utmost diversity obtains in these details, to the embarrassment of practitioners and the bewilderment of the public. It is high time that something like a general settlement should be arrived at; and we commend the attempt to the consideration of each of our Branches, as preliminary to a general debate of the whole Association—the Medical Parliament.

I am, sir, yours faithfully,

F.R.C.S.

CORONERS' FEES AND ARMY SURGEONS.

SIR,—I beg you will do me the favour of publishing the following facts. On January 2nd, I had to attend and give evidence in the case of a soldier, who had met his death in a sudden manner. The distance I had to go was over a mile. Everything went on smoothly, and the coroner, some days afterwards, called on me very kindly, and paid me my fee of £1 1s. The coroner, by the bye, is a lawyer. In the *Dover Telegraph* of the 3rd instant, I see that the Town Council has disallowed the fee, and ordered it to be deducted from the coroner's expenses. Is this either just or legal? Does it not show a spirit of meanness? Surely, as a medical man holding three English diplomas, I am as worthy of my hire as any other labourer in the profession. I lost a whole afternoon through the inquest. I may add, that the man met his death out of hospital. Supposing that the man had died in hospital, and a fee had been refused to me, accompanied by the statement, that I was not entitled to one, because the hospital was a public one (I have heard of this answer being given to an army surgeon), I would say it is not a public hospital, as the sick soldiers themselves are all under stoppages, and, to a *very great* extent, pay towards the hospital expenses. The question is a very important one, not only for army medical officers, but for all members of our profession. If a civil surgeon had seen the man first, his fee would have been allowed, and why should not mine? Of course, as in India, where Courts of Inquests are held by military officers, I should not be entitled to a fee; but, in this case, I had to attend and give evidence by order of the coroner; I had to walk more than a mile to the Court, and wait of course some time before I was called upon to give my evidence. The coroner, who I believe has held office for some years, and is a lawyer, gives me a fee; the Dover Town Council repudiates the coroner's act. Can you tell me if the council or coroner be right?

Your obedient servant,

JOHN G. RANDALL,

Dover, Feb. 6th, 1875.

L.R.C.P. Lond., Surgeon, A.M.D.

THE CONTAGIOUS DISEASES ACTS.

SIR,—As Dr. Parkes challenges me by name to reply to his articles, I accept the challenge, and will first take his letter of December 19th, 1874.

Decrease of Disease before the Acts acknowledged by Dr. Parkes, and his Explanation.—He himself acknowledges without reserve the great fall in disease before the Acts came into operation; and he attributes it to the reduction of numbers in the Army, by which means the bad rowdy men were got rid of, and the moral character of the Army was, therefore, improved by the removal of a bad element. I have not the slightest disposition to quarrel with him on this point. I attributed the reduction of disease to the elevation of the Army, morally and physically, by the introduction of various new moral and sanitary agencies, "and by others" not specified. He specifies one of the "others" as the chief agent; viz., the removal of a bad element from the Army, by which its general character was left in a higher state than before. I accept his aid cheerfully in showing that it was not the Acts, but the improved character of the soldiers, which caused the great reduction in venereal diseases before the Acts were passed.

Increase of Disease subsequent to the Acts acknowledged by Dr. Parkes, and his Explanation.—Dr. Parkes attributes the rise in disease subsequent to the Acts to the increase of the Army in consequence of the German war, which caused the admission of numerous recruits, who always bring an increase of disease, owing to their running riot for a time after their enlistment; and he gives his first table in his December letter to illustrate this. If he will take the trouble to work out the figures, he will find that, of the seven years from 1866 to 1872 inclusive, given in his table, there is only one year—viz., 1869—which corresponds even approximately with his explanation; and, in his table in his letter of January 23rd of this year, there is no relation whatever between the amount of disease and the number of new recruits. So far, therefore, as his own figures go, they fail to afford any proof of his theory; and the opponents of the Acts are still left to attribute the increase of disease to the belief of the soldiers and sailors "that the

years before the Acts; or one-sixtieth *per annum* instead of one-eighteenth.

And now, I ask Dr. Parkes, in his own words, "to look at *all* the Army statistics," and I must add the Navy statistics also, and the Metropolitan Police statistics, about the increase of disease and mortality amongst the registered prostitutes, and say what proof the Acts can show of reduction of disease superior, or even approaching, to what was taking place before their introduction. Gonorrhoea increased: secondary syphilis increased; invaliding increased; primary syphilis nearly doubled in the Mediterranean, and checked in its fall at home; and the reduction in the constantly sick also checked in its fall. And all this since 1866, the date of the beneficent and salutary Contagious Diseases Acts.—I am, Sir, yours faithfully,

J. BIRKBECK NEVINS, M.D. Lond.

Liverpool, January 30th, 1875.

ASSOCIATION INTELLIGENCE.

NORTH WALES BRANCH.

THE intermediate meeting of this Branch will be held at the Castle Hotel, Conway, on Tuesday, February 16th, at 12.30 P.M.: THOS. E. JONES, Esq., President, in the Chair.

Dinner at 3.30 P.M.

T. EYTON JONES, *Honorary Secretary, pro tem.*

Wrexham, January 19th, 1875.

BATH AND BRISTOL BRANCH.

THE fourth ordinary meeting of this Branch will be held at the York House, Bath, on Thursday, February 18th, at 7.15 P.M.: F. MASON, Esq., President.

R. S. FOWLER, *Honorary Secretaries.*
E. C. BOARD,

Bath, February 1st, 1875.

SOUTHERN BRANCH: EAST DORSET DISTRICT.

A GENERAL meeting of this District will be held at the London Hotel, Poole, on Thursday, February 18th, at 1.30 P.M.: H. D. ELLIS, Esq., President, in the Chair.

Business.—1. To promote combined action with the Bournemouth and West Dorset Districts.

2. To elect officers for the present year.

3. To appoint the number, places, and times of meetings during the year, and the amount of annual subscription.

Dinner at 4 P.M., at the London Hotel: charge, 5s., exclusive of wine.

C. H. WATTS PARKINSON, *Hon. Sec.*

Wimborne, January 31st, 1875.

METROPOLITAN COUNTIES BRANCH.

AN ordinary meeting of this Branch will be held at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Friday, February 19th, at 8 P.M., when Dr. Lockhart Clarke, F.R.S., will read a paper on Cases of Paralysis.

ALEXANDER HENRY, *Hon. Secretaries.*
ROBERT FARQUHARSON,

February 1st, 1875.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

ENTERIC FEVER AND MILK-INFECTION.

MILK is reported to have been the vehicle by means of which another outbreak of enteric fever has been caused. According to a report presented by Dr. G. C. Pirie to the Dundee Police Commissioners, it appears that, at the latter end of October last, a limited, but somewhat severe and fatal, outbreak of this disease appeared in Dundee. Some of those attacked were well-to-do persons, others were poor; they all used the general town water-supply from Monikie, against which no suspicion can well be raised; and, though in some of the houses affected means were found by which foul and sewer-air could enter the dwellings, yet this condition was evidently not sufficiently uniform to account for an epidemic which had occurred suddenly in one single district of the town. There was, however, one circumstance in common to all the patients; they all procured their milk-supply from the same dairy,

and, on inquiry, it was found that, between the months of August and December, four of the persons residing in the dairy had suffered from enteric fever. The milk-store opened into the apartment used by the sick during the earlier attacks; but it was not until a fortnight after this arrangement had been discontinued that the general outbreak commenced; and, from this circumstance, viewed in connection with some previous experience, we may perhaps infer that the contagium of this disease is not, as a rule, easily transmitted to milk by means of the atmosphere of the sick room. The contents of the well, which was in general use for all dairy purposes, was submitted to chemical analysis, and it was found to be contaminated with the "products of decomposing organic matter of the nature of sewage". This water had, however, long been in use, and, with a view of explaining how the specific infection of enteric fever can have gained access to it, Dr. Pirie points out that, though the soil around the well had for an indefinite period been fouled by soakage from dung-heaps in its immediate neighbourhood, it was not until about October last that the fecal evacuations of the sick, which had been thrown upon these dung-heaps, could have been carried by percolation into the soil surrounding the well. Up to the date of the report, at least nineteen persons had been attacked, and four had died. The well was immediately closed, and it is to be hoped that this step, associated with other precautionary measures, will stamp out the disease. It would have been interesting if, in addition to the above information, the report had stated the number of persons or of families using this milk, and the proportion of them attacked with the disease.

ENTERIC FEVER AT NEWQUAY, CORNWALL.

IN presenting his annual report on the sanitary condition of Newquay to the urban authority, Mr. W. Moorman gives an account of a severe outbreak of enteric fever, which had resulted in upwards of fifty attacks among the residents of that watering place, in addition to others which had appeared amongst visitors, and which had become developed in distant parts of the country. The disease first manifested itself in the families of two washerwomen, who had been washing the soiled bed-linen of persons suffering from "fever". The exact type of the fever under which these persons were labouring appears unfortunately to have been somewhat doubtful: on the one hand, it is alleged to have been scarlet fever, and, on the other, it is stated that there are good grounds for believing it to have been enteric fever. If the latter supposition be correct, the outbreak is interesting, as affording another instance of the propagation of enteric fever by means of linen soiled with the specifically diseased evacuations of a previous patient. But, if the bed-linen had in reality been used and soiled by scarlet fever patients, and it had subsequently been the means of conveying and distributing enteric fever, it can only have done so in the manner in which ordinary excreta, in common with organic matters, and especially sewage in a state of decomposition, are believed to be capable of developing the contagium of this fever by those who hold the pythogenic theory of its origin. To discuss the subject would be to open up the whole dispute between those who contend that enteric fever, like small-pox, is maintained solely by self-propagation, and those who maintain that there is evidence to show that the disease can arise without the necessity of an antecedent case. In this instance, however, there appear certain grounds for believing that the outbreak was due to importation, and that it was not an instance of spontaneous generation.

WATER-CLOSETS IN DUNDEE.

A LENGTHENED discussion took place at a recent meeting of the Dundee Police Commission, as to whether plans for building should be sanctioned, in which the water-closets were so situated that they could not be efficiently ventilated and lighted. It appears, that in Dundee, water-closets are at times situated within a foot or two of the beds in which people sleep, and that they also occupy the centre of dwellings. When it is remembered that every water-closet is provided with a pipe which enables sewer-air to pass up to the water-trapping, it must be obvious that such situations as these referred to are eminently unfitted for these closets. Light to insure perfect cleanliness, and efficient ventilation to prevent foul air from entering the houses, are conditions essential to a properly constructed water-closet; and wherever it is possible the closet should be separated from the house by a lobby which is provided with cross ventilation by means of windows.

VACCINATION.—Mr. Edward Marshall of Mitcham has received £14 11s. as his fourth gratuity from the Local Government Board as Public Vaccinator.

REGISTRATION OF DEATH.

SIR.—A case occurred a few days since which shows a great defect in the law of death-registration, if it have been correctly laid down for my information. I received a parish order to visit a poor woman who was said to be vomiting blood: the order was dated 5.45 P.M. I was told she had been doing so very frequently, and, as I saw, very profusely, ever since the woman who was with her had arrived, which was at twelve at noon on the same day. No information could be obtained as to how much longer it had been going on. Directions were given to send directly to my house, which was not three hundred yards distant, for medicines. This was not done for an hour. I heard nothing more till the next morning, when I was told, on calling, that the hemorrhage, which had ceased when I saw her, had returned some time after I had left, and that she had died before nine the same evening, having had something like a fit.

The following morning, the nurse came for a certificate of the death, which I refused, believing that the woman had not been sufficiently attended to, and that an inquest or inquiry of some sort was necessary. Hearing nothing from the Registrar or Coroner for three days, I called on the former, and found that the death had been registered without any certificate from me. The Registrar had called on the Coroner, and had given him the version of the tale which he had received from the nurse, without thinking it necessary to obtain any verification of it. On expostulating with him, he informed me that it was in no way his duty to pay any visit to the locality of the death, and that he was under a penalty not to refuse to register any death of which he received information. Surely here must be some mistake. I understood him to say that it was not a part of his duty to acquaint the Coroner with the circumstances of a doubtful death. Believing that registration could not be effected without either a certificate or an inquiry why one was not given, I had myself taken no steps in the matter, expecting to hear from one or other of the two officers. But is it necessary that medical men should do this? I can see a good reason there, at least why they should not. And is not an inquest as necessary in a case of neglect as in one of poison or suicide? INCERTUS.

MILITARY AND NAVAL MEDICAL SERVICES.

It is rumoured, says the *Army and Navy Gazette*, in well-informed circles, that a new Army Hospital Corps Warrant will become necessary, owing to the very general objection on the part of medical officers to the reimposition upon them of the charge of stores and equipment, from which they were relieved upon the recommendation of the late Lord Herbert's Committee, in order that they might have more time to devote to the higher duties of the profession.

ARMY MEDICAL SERVICE.—The following medical candidates were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School, Netley, February 1875.

1. Harrison, C. E.	5645	9. Gardner, R. H.	3680
2. Wellings, B. W.	5175	10. M'Quinn, J.	3678
3. Forrester, J. S.	4925	11. Powell, J.	3660
4. Smith, R.	4935	12. Carter, S. H.	3429
5. Trevor, F. W.	3955	13. May, W. A.	3447
6. Mullane, T.	3948	14. Bourke, G. D.	3427
7. Scott, H.	3775	15. Gardner, H. G.	3367
8. Campbell, W.	3755	16. Hysted, J.	2926

NAVAL MEDICAL SERVICE.—The following medical candidates were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School, Netley, February 1875.

1. O'Connor, D. W.	4113	4. Breton, W. E.	3215
2. Russell, A. W.	3595	5. Bourke, M. E.	2717
3. O'Callaghan, J.	3467	6. Whately, G. F.	2447

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Surgeon-Major W. A. Smith, M.D., in medical charge, 2nd Regiment Light Cavalry, has obtained leave, on furlough and medical certificate, to Europe for two years.—Surgeon J. Lloyd has obtained leave to Europe, on furlough and medical certificate, in anticipation of the furlough which will be granted to him by the government of his own Presidency.—Surgeon-Major G. B. F. Arden, who is at home on leave from Bermuda, has been posted for duty to the 68th Brigade Department at Galway.—Surgeon Owen has resumed his duty with the 50th Regiment.—Surgeon W. G. Routledge has been ordered to do duty with the 2nd Battalion 21st Fusiliers at Aldershot, until further orders.

THE PRINCIPAL CIVIL MEDICAL OFFICER IN CEYLON.

THE very important post of principal civil medical officer in Ceylon, which has been vacant for some time, has been lately filled up by the appointment thereto of Dr. William Raymond Kynsey, Surgeon, Army Medical Department, now on the staff of the Royal Victoria Hospital, Netley, and one of the members of the British Medical Association. Dr. Kynsey joined the Army Medical Department in 1863, and reference to the Blue Book of that year shows that he was placed within one of the head of the list of a very large number of competitors. He has since served with distinction in Ceylon, the field of his future labours, and lately on the Gold Coast during the Ashanti campaign, having accompanied the

42nd Highlanders on the march into the interior, and was present at the capture and destruction of Coomassie. Dr. Kynsey has shared in common with the other medical officers who were present during the late campaign on the Gold Coast the non-bestowal of the honours and rewards liberally showered on their more fortunate, so-called, "combatant", brother officers for living through this so aptly named "doctors' war", and it is, therefore, with real pleasure we find the merits of one, at least, of these medical officers, recognised and rewarded even in this very indirect manner. The importance of this post will be understood when we remember that Ceylon is an island nearly as large as Ireland, with a population of over 2,000,000. The post of chief adviser to the Colonial Government in all things sanitary and medical is, therefore, one of great responsibility, and we believe that Lord Carnarvon has acted most wisely in choosing one who possesses at the same time the special hygienic knowledge so well taught at the army medical school and duly acted on in the army, and the practical experience in tropical diseases, acquired only by serving in the countries in which they are endemic. Dr. Kynsey is fortunate in being adviser to a gentleman of such exceptional ability as Mr. Gregory, the present Governor of Ceylon, for we too often find that, while the needful advice in sanitary matters is to be had, the representatives of Government are either incapable of appreciating its value, or too careless to carry out the necessary measures.

SOME PRACTICAL GRIEVANCES OF MEDICAL OFFICERS ATTACHED TO REGIMENTS.

A CORRESPONDENT, at present stationed in South Africa, calls our attention to several practical grievances which result from the views taken regarding the position and claims of army medical officers attached to regiments. These grievances, which press especially upon married officers with families, he thinks have not been sufficiently noticed.

In the first place, a discrepancy between the *Army Circular* of March 1st, 1873, and that of August 1st, 1870, on the subject of the issue of fuel and light, leads to a considerable loss to the medical officer who has attained to the relative rank of a lieutenant-colonel. The former circular states that relative rank shall regulate choice of quarters, rates of lodging money, fuel and light, etc.; but the latter circular only provides for one lieutenant-colonel in a regiment; viz., the lieutenant-colonel commanding. A second lieutenant-colonel in a regiment, whether holding that rank by brevet or otherwise, gets only the allowances of a major or "field officer". A medical officer who has gained by promotion the relative rank of a lieutenant-colonel, though only attached to a regiment, at once becomes classed as a regimental officer, and, from being placed in the regimental list, gets no more allowance of fuel and light than he did before his promotion when ranking as a major. The injustice of this rule is all the more marked, because another surgeon-major of the same relative rank, if not attached to a regiment, draws the allowances laid down for a lieutenant-colonel. The difference represents a considerable sum of money in the course of a year, and is one of no little importance to a medical officer with a family. There can be no doubt that this grievance is a real one. It arises from an anomaly to which attention has been frequently called in our columns, and which ought to be swept away. The Control authorities consider the medical officers of the Army sometimes as regimental officers, sometimes as staff or departmental officers, just as a saving of money will be effected by one or other view. A rule ought to be laid down once for all, defining the exact position of the army medical officers in regard to all rates of allowances, and the officers should be so classified, that no double interpretation could be possibly admitted with regard to the emoluments to which their various ranks entitle them.

Another practical grievance to which our correspondent invites our attention is, that, while the Army regulations lay down the rule that "relative rank shall carry all precedence and advantages attaching to the corresponding military rank", with the exception of military command, and while the authorities persist in regarding a medical officer attached to a regiment as a regimental officer, and consequently compel him to join in every regimental expense, yet his title to the precedence due to his relative rank is systematically ignored, even in the smallest particulars. When it suits a purpose, he is a regimental officer; when it does not suit for him to be so, he is no longer a member of the corps. No position is assigned to him at mess entertainments, no reference is made to him in regimental matters, yet he must contribute to the expenses of the regimental band and mess, and join in all other regimental outlay, according to his rank. Civilian guests are especially at a loss to understand the position of an officer whom they see wearing the uniform of a regiment, with the lace and other distinguishing marks of a major or lieutenant-colonel, and yet without any place being assigned to him.

among his brother officers. Were the medical officer, our correspondent remarks, to be recognised as a departmental officer, and to wear a departmental uniform, the distinction between him and the other officers would be better appreciated, and the anomaly to some extent removed. Still the negation of all position and precedence must remain a source of mortification, especially while the medical officer is compelled to contribute so largely as he is at present required to do to regimental expenses. Our correspondent suggests that medical officers attached to regiments should be honorary members of the regimental messes, on the same basis as all other honorary members of corps and departments whose officers it is customary to make honorary members of military messes. He shows that the expenses in a regiment are much greater than they are generally supposed to be, and that, though some of the contributions and subscriptions included in them are stated to be voluntary, they are really only nominally so; for no one can refrain from complying with the usages of the Service, and joining in what the other officers with whom he is associated do in these respects, without exposing himself to an amount of contumely which few who value the esteem and good opinion of others will dare to incur. We have frequently remarked on the incongruity and unfairness of regulations, or customs, by whatever name they may be called, through which, on the one hand, a medical officer is disowned as a member of a regiment in all that touches his *amour propre* and self-respect; but, on the other hand, is fully acknowledged to be such in all matters that touch his pocket; and we can only now express our astonishment that such a disregard of common justice is permitted to continue. Obviously, the medical officer should either cease to pay to support the regimental *prestige* and credit, or, if compelled to pay, he should have the same voice in its affairs as any other officer, and should enjoy all the precedence and privileges due to his particular rank in the Service.

We have so recently commented upon some of the other grievances which our correspondent mentions in his communication, that we think it unnecessary to advert to them in the present remarks.

THE NEW NAVAL MEDICAL WARRANT.

The following Order in Council has been issued.

At the Court at Osborne House, Isle of Wight, the 4th day of February, 1875. Present: The Queen's Most Excellent Majesty in Council.

Whereas there was this day read at the Board a memorial from the Right Honourable the Lords Commissioners of the Admiralty, dated the 1st of February 1875, in the words following:

"Whereas we have had under our consideration the position of the medical officers of your Majesty's Navy, and whereas we are of opinion that it will be for the benefit of your Majesty's service that the following regulations shall be established, we beg to submit them most humbly for your Majesty's approval:

"1. That surgeons on entry shall have the same relative rank as paymasters, chief engineers, and naval instructors—namely, shall rank with lieutenants under eight years seniority, and shall have uniform corresponding to such relative rank.

"2. That staff-surgeons shall be denominated 'fleet-surgeons', and staff-surgeons second class, simply staff-surgeons; the distinction in rank between these two grades to be denoted by a small difference in the uniform.

"3. That inspectors-general shall be compulsorily retired at the age of sixty on £2 per day, provided they shall have completed the period of service now required to entitle them to the maximum half-pay of their rank.

"4. That deputy inspectors-general shall be compulsorily retired at sixty, if in the first six of their rank, at 33s. per day, others at 30s. per diem, provided that they shall have completed the period of service now required to entitle them to the maximum half-pay of their rank.

"5. That fleet-surgeons and staff-surgeons shall be placed on the same scale of retirement as chaplains and naval instructors, secretaries, paymasters: that is, the maximum to be £450 per year instead of £400.

"6. That any fleet-surgeon shall have the option of retiring after twenty years' full pay service in all ranks at 15s. per day, and after twenty-five years' service at 21s., subject in each case to our approval; but that of those now on the list, no more than ten shall retire under this clause in each year (the officers having the option according to seniority) unless we should approve (with the consent of the Lords Commissioners of your Majesty's Treasury), of a large number so retiring.

"7. That of the medical officers to be hereafter entered, all shall have the option of so retiring, subject to our approval in each case; and we beg leave to represent to your Majesty that the Lords Com-

missioners of your Majesty's Treasury have signified their concurrence in the proposed arrangements."

Her Majesty having taken the said memorial into consideration, was pleased, by and with the advice of her Privy Council, to approve of what is therein proposed. And the Right Honourable the Lords Commissioners of the Admiralty are to give the necessary directions herein accordingly.

ARTHUR HELPS.

THE ARMY MEDICAL SERVICE.

SIR,—I think it must be admitted that the first effort of the department to unify itself is rather a failure. Concession after concession is an admission that there was something impracticable in the early attempt. As all seem to agree that the regimental hospital is unsuitable to time of war, I doubt whether the authorities are prepared to recommend the restoration of the medical officers to regiments on their former footing, as suggested by Surgeon-General Monat in his excellent pamphlet. If they be not fully prepared to endorse his recommendations, I would suggest that the brigade-system as regards hospitals should be the unit on which to organise and distribute the medical department. Although I propose to attach two surgeons to each regiment of infantry and cavalry, I would not restore the surgeon-major to a regimental position. Wherever there is a hospital (call it "station hospital" in small garrisons; "brigade hospital" in larger garrisons; and where there is a "general hospital", subdivide it by brigades). I would locate a surgeon-major. I do not think the admixture of sick should take place to a greater extent than by brigades. This would get over a difficulty which now exists in large hospitals of mixing up infantry, cavalry, artillery, and departmental corps. It would further facilitate the visiting of corps by brigadier-generals, regimental officers, and officers commanding or belonging to corps; and mitigate the complaint now made by these officers that "they cannot find their own men". The surgeon-major in charge should be assisted in the treatment of the sick by one of the regimental surgeons of each regiment. The other regimental surgeon would perform the duties appertaining to the regiment. A brigade staff of warrant and non-commissioned officers of the Army Hospital Corps should, with and under the surgeon-major, form the permanent staff of the hospital. The orderlies should be regimental. Whatever dress be decided on, medical officers, warrant and non-commissioned officers, and orderlies, should wear a distinguishing badge; and none yet designed is, in my opinion, more suitable than the Geneva cross.

I am, etc., SURGEON-MAJOR.

OBITUARY.

ALEXANDER MCFIE SMITH, M.D., GOVAN, GLASGOW.

THE village of Govan, which now constitutes the south-west suburb of Glasgow, has recently been deprived by death of two of its most important public men. The Rev. Dr. Leishman, father of Professor Leishman of Glasgow, after having fulfilled the duties of Parish Minister for upwards of fifty years, died at a ripe old age, beloved and respected by all his parishioners and the whole community. A week or two prior to his death, Dr. Smith, the medical man holding the most important practice, died after a short and rather obscure illness. Dr. Smith was a native of Glasgow, and pursued his studies in its medical school. After passing through a lengthened curriculum, and acting as resident clerk in the medical and surgical departments of the Royal Infirmary, he took the degree of M.D. in the University of St. Andrews in 1850, and the Diploma of Surgeon in Edinburgh. Soon after receiving his qualifications, by the advice of the late Dr. Lawrie of Glasgow, he commenced practice in Govan, and soon acquired the confidence of those around. Shortly after he settled there, the district around began to be developed in an unprecedented manner. The ship-building yards of Napier, Elder, and many others, drew round them an immense population of the mechanic class; while the fewing grounds of Ibrox towards the country were soon covered with villas, crescents, and terraces, in which many of the wealthy merchants and engineers, especially those having works on the south side of the town, resided. Dr. Smith's practice soon became both extensive and lucrative, and he was justly esteemed, both by his patients and professional brethren, for his great sagacity and his thoroughly upright and honourable conduct. Dr. Smith never applied for nor obtained any public appointment, but was received, not only as the medical attendant, but the confidential adviser of the families who placed themselves under his charge.

For some years past, Dr. Smith had not been in robust health, though no well defined disease was present. He was in the habit of leaving his practice in autumn, when many of the families in his neigh-

bourhood were absent at country or coast. In these holidays, he frequently went abroad, and travelled in Switzerland, Italy, Norway, etc., and always came back invigorated by the change.

Five or six weeks before his death, he had a very violent attack of hemiplegia and toothache, for which he had some decayed tooth-stumps removed by the advice of the surgeon he consulted. This produced a partial and temporary relief, so that he was able to go to the Island of Arran, where his family were residing. The pain returning, however, he came back to Glasgow, accompanied by his wife. Some chest-symptoms having been discovered by Dr. Gardner of Govan, who for the time was taking charge of his practice, Professor Gairdner was asked to see him, and, along with Dr. George Buchanan, visited him till the end. Rapid and unaccountable sinking soon came on, accompanied by pain in the head and general uneasiness. He could neither take opium nor stimulants. Two days before his death, an eruption, closely resembling that of typhoid fever, showed itself, and from that time he never rallied.

Dr. Smith, who was in comfortable circumstances, died in the prime of life, about 48 years of age, leaving a wife and five children.

JOHN TROTTER, M.D., DURHAM.

AFTER a long and useful professional career, Dr. Trotter died lately at his residence in Old Elvet, Durham, at the advanced age of 79. The family of Trotter, according to Burke, "is of great antiquity in the county of Durham". So far back as the fourteenth century, the family were settled at Byers Green. The late Dr. Trotter was the eldest son of John Trotter, Esq., who, at the time of the threatened French invasion of this country, raised and equipped at his own expense and commanded a troop of yeomanry. He was also Major-Commandant of the Darlington Volunteers, and lived to his 90th year. Dr. Trotter was married to Mariannie, eldest daughter of the late Rev. John Fawcett, M.A., of Newton Hall, near Durham, by whom he had a large family, the eldest of whom is Mr. John William Trotter, senior surgeon in the Coldstream Guards. Dr. Trotter chose the medical profession, and, in the year 1819, he became a graduate of Edinburgh University; after which he settled in Durham. His reputation stood very high as a physician. For upwards of half a century he was the principal member of the medical staff of the Durham Infirmary, subsequently the County Hospital, but, in July 1871, he resigned the position of physician, owing to his great age. On his retirement, the governors presented him with an illuminated address, expressing, in most feeling language their high respect and warm attachment, and their sentiments of gratitude, on their own part and on behalf of every supporter of the hospital, as well as of the afflicted whose sufferings he had mitigated and removed. In 1861, the University of Durham conferred upon him the honorary degree of M.D. In accordance with an expressed wish of the deceased, the funeral was of a private character, those present consisting, for the most part, of the members of Dr. Trotter's family, his professional brethren, and a number of the city tradesmen.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Monday, February 8th, 1875.

The Factory System in India.—Mr. ANDERSON asked the Under Secretary of State for India if he was aware that an extensive factory system was growing up in India, without any Government supervision for the protection and health of the women and children employed; whether his attention had been drawn to statements that these women and children are systematically worked for sixteen hours a day, and in many cases even including Sundays; and whether the Indian Government would adopt some such factory legislation as existed in this country for the prevention of such evils before they attained greater proportions.—Lord G. HAMILTON said that communications on the subject had been held with the Indian authorities. Major Moore, who was connected with the presidency of Bombay, in which the greater part of the women and children to whom the question referred were employed, had informed the Government that the hours of labour were long. A dispatch had been directed to the Governor of Bombay on the subject. Representations had been made to the Secretary of State for India respecting the evil effects of the present system, and the subject was receiving careful attention.

Dwellings of the Working Classes.—Mr. Secretary CROSS, in asking leave to introduce a Bill for facilitating the improvement of the dwellings of the working classes, explained that it was purely sanitary, and

that he proposed to confine it in the first instance to the metropolis and the large towns of England. The authorities who would have to carry it out were the Corporation in the City of London, the Metropolitan Board of Works in the rest of the metropolis, and the town councils in the large towns. It would be put in motion by the medical officers of health, who would report to the authorities when a place was an unhealthy district. An improvement scheme would then be prepared and submitted to the Home Secretary, who, if he sanctioned it, would pass it as a provisional order through Parliament, and to save expense. Powers would be given to acquire land, the value of which would be fixed by arbitration. The corporation or town council, however, were not to be the builders, but facilities would be given to private persons to supply the money required, and there was a large amount of floating capital which would be employed in this way but for the want of compulsory powers to acquire land. It was not intended to mix up the plan in any sense with the borough rate, from which it would be kept entirely separate.—Mr. KAY SHUTTLEWORTH expressed a hope that a sufficient time would elapse before the second reading for a consideration of its provisions. The whole measure seemed to depend on the action of the medical officers, and he trusted that they would be placed in a position of greater independence than that which they now occupied. With respect to the action of the local authorities, the right hon. gentleman had not stated what restrictions they would have the power of placing on those who might build on the sites provided under the Act.—Sir S. WATERLOW congratulated the right hon. gentleman on the measure which he had introduced. He feared that if the origination were to depend upon the medical officers, there must be some external power to stimulate them to action. He knew that in many large vestries and local bodies the members would exercise their power over the medical officers to prevent proceedings which would affect their pockets.—Mr. WADDY had doubts as to the wisdom of placing the origination of the work in the medical officers, as they were appointed by the vestries, who would desire to save money, even at the expense of the poor. If the work were to be done in any way by private effort, he was afraid that there would be more attention to the rate of dividend than the welfare of the poor. If the Bill did not contain within its "ambit" powers over existing dwellings (and that without altering their structure), a great part of the evil they wished to remedy would be untouched. He hoped to see a clause in the Bill by which every landlord should be compelled to provide proper water-supply and accommodation for every single tenancy in each building.—Mr. CROSS, after a few words in defence of medical officers, expressed a hope that the House would read the Bill a second time on Monday next, with the understanding that some little time would elapse before it went into committee.—Leave was then given to bring in the Bill.

Universities of Scotland.—Mr. COWPER-TEMPLE obtained leave to bring in a Bill to remove doubts as to the power of the Universities of Scotland to admit women as students, and to grant degrees to women.

The Contagious Diseases Acts.—Mr. H. RICHARD, in the absence of Sir H. Johnstone, obtained leave to bring in a Bill to repeal the Contagious Diseases Acts, 1864, 1866, 1868, and 1869.

Labourers' Dwellings in Ireland.—Mr. BRUEN obtained leave to bring in a Bill to encourage the erection and improvement of dwellings for agricultural labourers in Ireland.

Coroners in Ireland.—Mr. VANCE obtained leave to bring in a Bill to regulate the office of coroner in Ireland.

Labourers' Dwellings in Scotland.—Mr. FORDYCE obtained leave to bring in a Bill to facilitate the erection of labourers' cottages and farm-buildings in Scotland.

Tuesday, February 9th.

Lighting, Paving, and Cleansing of the Metropolis.—Sir W. FRASER moved a resolution to the effect that the condition of the metropolis as regarded lighting, paving, and cleansing, demanded legislation.—After discussion, the motion was withdrawn, after Mr. Secretary CROSS had thrown out an invitation to the mover to arrange his ideas in the form of a Bill.

Infanticide.—Mr. CHARLEY brought in a Bill to amend the law relating to infanticide.

Notices of Motion.—The following notices have been given. Mr. Slater-Booth: Bill for consolidating and amending the Acts relating to Public Health in England (Thursday, February 11th). Mr. Slater-Booth: Bill to repeal the Adulteration of Food Acts, and to make better provision for the sale of Food and Drugs in a pure state (Friday, February 12th). Colonel Beesford: Bill for improving the Supply of Water to the Metropolis (Friday, March 5th).

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board, on February 4th.

Messrs. William Hardman, M.B. & C.M. Edin. and L.S.A., Blackpool, Lancashire, diploma of membership dated July 28th, 1870 (of University College and Middlesex Hospitals); George Herbert Lilley, Ware, Herts, May 20th, 1874 (of University College); George Albert Hamerton, L.S.A., Infirmary, Lambeth, July 23rd, 1874 (of St. Thomas's Hospital); and Charles Morgan Jones, Aberdare, South Wales, July 29th, 1874 (of St. Thomas's Hospital).

Two candidates having failed to acquit themselves to the satisfaction of the Board, were referred to their studies.

QUEEN'S UNIVERSITY IN IRELAND.—At the annual conferring of Degrees of this University, held in St. Patrick's Hall, Dublin Castle, on Wednesday, October 14th, 1874, Sir Dominic Corrigan, Bart., M.D., Vice-Chancellor, conferred the following Degrees in Medicine and Surgery. [The names of the successful candidates given in the lists at page 192 of the JOURNAL for August 8th, were announced at the same time.]

Allen, James F. (C), M.D., C.M., Midwifery Diploma.
 Balbirnie, Hugh de V. (B), M.D., C.M.
 Beamish, Robert T. (M.D.), C.M.
 Blackall, John J. (C), M.D.
 Browne, David Graham, B.A., M.D. (B), Midwifery Diploma.
 Clapp, Albert J., M.D. (C), C.M.
 Colthurst, Ludlow T., B.A. (C), M.D., Midwifery Diploma.
 Campbell, Arthur R. (B), M.D. (Upper Pass Division).
 Crofts, James, M.D. (C), C.M.
 Daly, Maurice C., B.A. (C), M.D., C.M., Midwifery Diploma.
 Drury, Richard J., B.A., M.D. (G), Midwifery Diploma.
 Frazer, R. Johnson, B.A. (G), M.D. (1st Honour Class), C.M., Midw. Dipl.
 Graham, William (B), M.D.
 Greany, John P., M.D. (C), C.M.
 Guthrie, James (B), M.D.
 Hamill, J. Wilson, M.D. (B), C.M., Midwifery Dipl.
 Henry, Joseph (G), M.D. (2nd Honour Class).
 Jennings, William (C), M.D., C.M., Midwifery Diploma.
 Le Grand, William J. (C), M.D. (1st Honour Class), C.M., Midwifery Dipl.
 Lyons, William J. B. (B), M.D.
 McClure, Harry (B), M.D., C.M., Midwifery Diploma.
 Marks, (Charles F.) (G), M.D.
 Martin, Samuel E., M.A. (B), M.D.
 Neville, Thomas (C), M.D., C.M., Midwifery Diploma.
 Parker, Joseph (B), M.D. (2nd Honour Class), C.M.
 Planner, Charles J. (B), M.D. (1st Honour Class).
 Pollock, Norman (B), M.D., C.M.
 Ross, James (B), M.D.
 Ryan, Michael R. (C), M.D., C.M.
 Speer, William S. (B), M.D., C.M., Midwifery Diploma.
 Tidbury, Robert, M.D. (C), C.M.
 Warren, John M. (G), M.D.

The following candidates were also reported as having passed the Second University Examination in Medicine, October 1874.

First Honour Class: Richard Francis Starkie (C), John Jacob Welply (C), Arthur A. Woods (B). *Second Honour Class:* Gilbert Kierke (B), Wm. McGeagh (B). *Upper Pass Division:* Charles Henry Bennett (C), Francis Conolly (G), Wm. Corry (B), John Davies, Hugh Latimer Donovan (C), Richard Jennings (C), Edward J. Kennedy (C), Robert M'Yver (B), Charles Mazill (B), Patrick Joseph O'Sullivan (C), Turner W. Pooler, Henry Tomkins, Francis Henry Walmesley (B). *Also Passed:* William Allen (G), Robert Allen Brannigan (B), Daniel Burdon (C), William Crofts (C), James Carroll Daly (C), Arthur Derham (C), John Danbar Dickson (G and B), John T. Dillon (C), John Stephen Dobbey (G), Justin F. Donovan (C), Robert E. Donovan (C), Michael Dundoo (C), Robert Eccles, M.A. (B), Chas. J. Fahie (C), John Curten Harnett (C), Denis Harrington, Wm. Hayes (C), Wm. John Irvine (B), Robert J. Kennedy (C), William Leonard (G), George Stanley Murray, John Richard Oliver (C), Michael U. O'Sullivan (C), Robert H. Robinson, Wm. John Stevenson (B), David Taylor (B), John Fredk. Wales, B.A. (B), Archibald Wallace (B), John Wilson (C).

The following were reported as having passed the First University Examination in Medicine, October 1874.

Second Honour Class: Michael Joseph McCarthy (C). *Upper Pass Division:* Samuel Alexander (B), Samuel Bateman (B), Henry C. Brannigan (B), John R. Galvin (C), Charles Graham (B), Jeremiah Mullane (C). *Also Passed:* William Henry Bracken (B), John Cahill (C), Thomas Paterson Delvin (B), Jas. A. Gordon (B and G), Robt. J. Hamill (B), James Palmer Hanrahan (C), John Leonard (C), Henry M'Cormick (G), Thomas Frederick M'Feece (B), Henry M. Madden (C), James Matthews (B), John Wesley Megarry (B), Thomas Newburgh (C), Daniel O'Connor (C), Henry O'Neill (B), Gervase Robert Percy (B), Samuel Phillips (C), J. C. Greatrakes Sandiford (C), John Sheedy (C), Wm. John Sprott (B), John Edward Walsh (C).

Exhibitions Awarded at the Second University Examination in Medicine.—John J. Welply (C), first; £20 a year for two years. Arthur A. Woods (B), second; £15 a year for two years.

In the above lists (B) signifies Queen's College, Belfast; (C), Queen's College, Cork; and (G), Queen's College, Galway.

MEDICAL VACANCIES.

The following vacancies are announced:—

ABBEYLEIX UNION—Apothecary.
ALDERBURY UNION—Medical Officer for the Fourth District and the Workhouse.
ARMY MEDICAL DEPARTMENT—Surgeons. Applications to be made to the Director-General of the Army Medical Department.
ASHTON-UNDER-LYNE UNION—Medical Officer for No. 3 District.
BARONY PAROCHIAL HOSPITAL, Barnhill, Glasgow—Dispenser.
BECKETT HOSPITAL AND DISPENSARY, Barnsley—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.
BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN—Resident Medical Officer. Salary, £80 per annum, with board, washing, and attendance. Applications to be sent in not later than March 3rd.
DERBYSHIRE GENERAL INFIRMARY—Assistant House-Surgeon. Board, lodging, and washing, but no salary. Applications to Secretary.
DOWNHAM UNION—Medical Officer for No. 6 District.
EMSWORTH—Certifying Factory Surgeon.
ESSEX LUNATIC ASYLUM—Second Assistant Medical Officer and Dispenser. Salary, £100 per annum, with board, lodging, and washing.
FLAX MILLS FRIENDLY SOCIETY—Medical Officer. Salary, £110 per annum. Applications to A. M'Keeman, 7, Hunston Square, Johnstone, N.B.
FULHAM UNION—Medical Officer for the Fifth District.
GRANTHAM UNION—Medical Officer for the Ropsley District. Salary, £26; 10 per annum.
HARDINGSTONE UNION—Medical Officer for the Brafield District. Salary, £45 per annum.
HARRIS, Parochial Board of—Surgeon. Salary, £66 per annum, including vaccination and medicine for the poor. The gentleman elected will get £90 per annum for attending the ratepayers and cottars within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.
HEADINGTON UNION—Medical Officer for the Wheatley District. Salary, £70 per annum.
HENDON UNION—Medical Officer for the Willesden District. Salary, £40 per annum.
INDIAN MEDICAL SERVICE—Twenty appointments as Surgeon. Examination in February 1875.
KENMARE UNION—Medical Officer for the Kilgarvan Dispensary District. Salary, £100 per annum, and fees, with £20 per annum as Sanitary Officer. Applications to be sent in on or before the 18th instant.
KILBURN DISPENSARY—Assistant Resident Medical Officer. Salary, £80 per annum, with apartments.
KILLALA UNION—Medical Officer for the Workhouse, and the Killala Dispensary District. Salary, £50 and £110 per annum, respectively, and fees. Applications to be made on or before the 20th instant.
LLANELLY UNION—Medical Officer and Public Vaccinator for the Kidwelly Union. Salary, £20 per annum, and fees. Applications to be sent in on or before the 17th instant.
MILFORD UNION, co. Donegal—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.
MORVEN, Parish of, Argyshire—Medical Officer. Salary, £100 per annum. Applications to H. A. Fraser, Morven, N.B.
NORTH WALES COUNTIES LUNATIC ASYLUM—Assistant Medical Officer. Salary, £100 per annum, with board, washing, and lodging. Applications to be made on or before February 17th.
REDDITCH AND DISTRICT MEDICAL ASSOCIATION—Medical Officer. Salary, £150 per annum, with fees and unfurnished house.
ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—Physician. Applications to be made on or before February 15th.
ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road—Physician.
SAFFRON WALDEN UNION—Medical Officer for the Seventh District. Salary, £86 per annum.
ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.
SALOP INFIRMARY—Assistant House-Surgeon.
SEAMEN'S HOSPITAL—House-Physician. Salary, £120 per annum, with furnished rooms and attendance. Applications on or before the 22nd instant.
SOUTH ESSEX DISPENSARY—Surgeon.
TYNEMOUTH UNION—Vaccination Officer.
ULVERSTONE UNION—Medical Officer for the Hawkshead District. Salary, £50 per annum.
UNIVERSITY COLLEGE HOSPITAL—Resident Medical Officer. Applications not later than February 15th.
UNIVERSITY OF EDINBURGH—Additional Examiner in Medicine.
WEST WARD UNION—Medical Officer for the Patterdale District.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

NORTON.—On January 25th, at 8, Redcliff Hill, Bristol, the wife of John Alexander Norton, M.B., of a son.

MARRIAGES.

HAVARD—ROWLANDS. On February 10th, at Cardiff, by the Rev. H. Oliver, B.A., Newport, Monmouthshire, David Havard, L.R.C.P., etc., of Newport, Pembrokeshire, to Julia Anna, the eldest daughter of John Rowlands, Esq., Penrhyn Villa, St. Andrew's Crescent, Cardiff.

POWELL-STEVENS.—On February 2nd, at Lyonsall Church, Kingston, Hereford, by the Rev. W. Winstone, uncle to the bride, assisted by the Rev. Mr. Green, Vicar of the Parish, Evan Powell, L.R.C.P., of Senny Bridge, Brecon, to Alethea Barton Stevens, of Lyonsall. No cards.

DEATHS.

***WHITE**, Frederick Blundstone, M.D., formerly Assistant-Surgeon 73rd Regiment, and Physician to Tetbury Dispensary, at Tetbury, in his 83rd year, on February 4th.

***KENNEDY**, Angus, M.R.C.S., Surgeon to South Essex Dispensary, and Certifying Factory Surgeon, at Stratford Hall, Essex, aged 70, on February 7th.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Ophthalmic, 2 P.M.

WEDNESDAYSt. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2.30 P.M.—Samaritan Free Hospital for Women and Children, 2 P.M.—Cancer Hospital, Brompton, 2 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Royal College of Surgeons, 4 P.M. Mr. W. K. Parker, "On the Structure and Development of the Skull." Medical Society of London, 8.30 P.M. Dr. S. O. Hershon, "On some Cases of Abdominal Disease." Dr. Drysdale, "On the Anatomy and Treatment of Tertiary Syphilis." Mr. Spencer Watson, "On Obstructions of Lacrymal Sac and Nasal Duct."

TUESDAY.—Pathological Society of London, 8.30 P.M. Mr. Cripps: Fatty Degeneration of Muscles of Thigh. Dr. Greenfield: Contraction of Coronary Arteries. Dr. Greenfield: Obstruction of Renal Artery. Dr. Greenfield: Fibroid Disease of the Heart. Mr. Butlin: Fatty Tumour removed in course of Herniotomy. Dr. Barlow: Aneurism of the Heart. Mr. Hulke: Specimens of Epithelioma. Mr. Marsh: Malignant Disease of Testis. Dr. Douglas Powell: Aneurism of Aorta. Mr. Barwell: Myeloid Sarcoma of Humerus. Mr. Godlee: Blood-Cyst in Sarcoma. Dr. Dwyer: Congenital Deformity of Clavicles (living specimen).

WEDNESDAY.—Royal College of Surgeons, 4 P.M. Mr. W. K. Parker, "On the Structure and Development of the Skull."

THURSDAY.—Royal College of Surgeons, 4 P.M. Mr. W. K. Parker, "On the Structure and Development of the Skull." Medical Microscopical Society, 8.15 P.M. Dr. W. B. Woodman, "On a Natural Method of Mounting certain Microscopic Specimens."

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. F. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

M.D. Carlisle.—Consult the Roll of the College of Physicians by Dr. Munk. Charles, Duke of Richmond, who died in 1759, was a Fellow of the College.

ENTERIC FEVER.

SIR,—Enteric fever has recently appeared in a house whose well is in close proximity to an old and hitherto forgotten drain, which ran from a neighbouring churchyard, in which was interred, two or three months ago, a person who died of enteric fever. In the absence of any other recent cases, in this little pollution of well-water from the churchyard was the cause of the outbreak. If so, can any of your readers say (1) how long the churchyard drainage will be capable of causing the specific fever? The soil is a heavy marl. (2) May not the individual body (which was brought from a distance) be the cause of the appearance of the fever? If so, here is another strong argument in favour of cremation. From time to time, during many years, apparently sporadic cases of enteric fever have occurred in the immediate vicinity of the house mentioned. I am, sir, your obedient servant, February 8th, 1875.

SANTAS.

A CARD.—"35, Colchester Road, Redcliffe Square. Medical advice, by a physician, every morning before 9 o'clock (Saturday excepted). Fee, one shilling, including medicine. 35, Colchester Road, Redcliffe Square, West Brompton." On turning to the *Medical Directory*, we find this to be the address of a Mr. Charles Richard Cutmore, M.R.C.S. Eng. and L.M.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following were the questions on surgical anatomy and the principles and practice of surgery submitted to the candidates at the written examination for the diploma of membership of the Royal College of Surgeons, on 22nd January. Candidates were required to answer at least four (naming one of the first two) out of the six questions. 1. Describe the operation of tying the external iliac artery, and state how the collateral circulation would be established. 2. What noisels may act to displace the fragments in fracture of the lower jaw, in various parts of the bone? 3. Describe the structure of, and mode of healing by, granulations. 4. What symptoms, before operating, would lead you to conclude that the contents of a hernial sac are in a state of gangrene? and what treatment would you adopt in such a case? 5. When the radius of the ulna is broken alone, at what part of the bone, in either case, does the fracture usually occur? State the reason why these particular fractures happen, and how you would treat them. 6. Enumerate the several causes of retention of urine in the male, and describe the means you would adopt in each case for its relief. The following were the questions the following day on the Principles and Practice of Medicine: 1. Describe a case of typhoid fever, giving the incubation, the various stages of the disease, the process which goes on in the intestines, together with the modes of death, and the treatment. 2. Define and illustrate the following terms—puerile respiration, bronchophony, pectiloquy, ægophony, fine crepitation, sibilant râles, cracked pot sound, metallic tinkling, dullness on percussion. 3. Mention some of the principal causes of vomiting, and the remedies you would use to arrest it. Write two of the prescriptions in full.

OBSTETRICIAN (Falmouth).—In the *Englishwoman's Journal* for March 1862, Dr. Gregory of Boston, United States, informs us that on a tombstone in a churchyard of the city of Charlestown appears the following, showing that bishops exercised the prerogative. "Here lies interred the body of Mrs. Elizabeth Phillips, wife to Mr. John Phillips, who was born in Westminster, in Great Britain, and commissioned by John, Lord Bishop of London, in the year 1718, to the office of a midwife, and came to this country in the year 1719; by the blessing of God, has brought into this world above 5000 children. Died May 6th, 1761, aged 76 years." The Archbishop of Canterbury has the power of granting the degree of M.D., but the title so obtained is not registrable.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS, IRELAND.

SIR.—As one of the licentiates of the King and Queen's College of Physicians, Dublin, I must enter my protest against the course taken by the dissentients to the proposed new charter, and the statement that they "object on behalf of the 1,200 licentiates." My own belief is that the new charter will benefit the institution, and those who possess the license at present who are excluded in most instances from hospital appointments; formerly fellows and licentiates of a college could hold an office connected with an institution of this kind; but of late years the rules have been altered so that nearly all the licentiates are favourable to the new charter, as it would restate them to that position they held before the other colleges thought fit to institute the grade of member, and constituted their license as of third-rate worth. From yours obediently,

L.K.Q.C.P. OF NINE YEARS' STANDING.

DR. DAVIS.—The name of "Dr. Forsyth Brown", recently convicted of an indecent assault, cannot be found in either of the Medical Directories, the *Medical Register*, or *Calendar of the College of Surgeons*.

CONTAGION OF PUERPERAL FEVER.

SIR.—The letter of your correspondent "Obstetricus", in the JOURNAL of January 23rd, seems to be of such vital importance to the interests of the profession, that I have been surprised at its not receiving more attention than it has hitherto done. If your columns were opened to a discussion on this all-important subject, I believe an immense amount of good would result to the profession.

Surgeons from time to time have been attended in their confinements by midwives; and, at the inquest, generally inform the coroner and jury that it is not safe for any person (surgeon or midwife) to attend a labour for periods of time varying from one to three months after having attended a case of puerperal fever, as it is by such agency that the disease is spread.

I consider, in the interests of the profession, that by such unqualified statements, a great harm is being constantly done to the profession. I have in my time attended some hundreds of cases of labour; and, on the whole, have lost very few mothers. In fact, I have attended as many as four hundred consecutive cases without losing a single mother.

On beginning practice for myself in this locality, my good fortune seemed to leave me, as I lost at intervals one case from scarlet fever, one case from small-pox, and finally, in October last, one from puerperal pyæmia; and again, in November, one from the same cause in the same street. In this last case, I did not deliver. I had examined the case, and found everything all right; and, on my again going, I found the child born, and the placenta came away most easily. This happened about the time that one of the inquest cases I have before mentioned appeared in the paper.

I was persecuted by the friends of the deceased. I was told I had given her the disease; that it was said in the paper that no surgeon should attend a case for three months after having had a fatal case. I was threatened with an inquest. Women who had engaged me to attend them were warned not to employ me; that if I attended them, they would surely die. I hope it is unnecessary for me to state that I took every possible precaution to prevent myself from carrying the disease about with me. But as I knew an absence of three months would simply have ruined me, and would not in my mind have made my attendance upon future cases any safer than an abstinence for three weeks, I resumed practice at the end of fourteen days, having previously disinfected; and am thankful to say that I am, and having had the rest carefully disinfected; and am thankful to say that the minds of my patients would never have been imbued with the notion that I conveyed the fever to the deceased. Hoping to hear the opinions of experienced practitioners on the subject,

I am, sir, yours truly,

JUNIOR.

February 1875.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

REDDITCH MEDICAL ASSOCIATION.

SIR,—I am indebted to a gentleman in London for a copy of your paper a week after date of issue, and my attention is called to an editorial article on the "Redditch and District Medical Aid Association." Permit me to say I am a member of one of the friendly societies at Redditch, and have been so for more than twenty-three years, and early in March last was appointed one of three delegates to attend an united committee of the different societies, called by circular, to consider "the unsatisfactory working of the medical department", and also "what steps can be taken to place this very important department in all sick benefit societies on a more satisfactory basis." The question did not originate with me, nor with the society to which I belong.

I was requested to act as secretary, after two others had been proposed and had declined. Seeing the extent of the dissatisfaction, and feeling the importance of the question, I consented. I have had no pecuniary interest in the matter, at least in the way of receipt, and do not know that I shall have.

After six months' inquiry, an account of their deliberations, and the "better system" they recommended, as a remedy, was published in the *Redditch Indicator*, and the *Bromsgrove, Droitwich, and Redditch Messenger*, where we innocently thought such information would be most needed. The direct result is that if you had been furnished with this information, which, in justice to yourself and to them, you ought to have been by the person who sent you the communication upon which the most objectionable parts of the article are based, your article would have been considerably modified. The directors wish me to say that there is but one medical gentleman in Redditch of any standing, as to time; that he alone deserves and receives the general respect of the members they represent; but, having a large private practice, he cannot meet their united requirements.

The handbills were not circulated until some time after the conclusions of the united committee had been made known by the means above referred to. They were found to be a necessity, in consequence of the numerous applications for information upon the subject, and they contain no statement in the way of inducement to persons to become members that is not carried out by similar associations by even smaller payments. I enclose report of one at Worcester for 1873, not having a later one. The junior members pay one shilling a year, and, by looking at the balance-sheet, you will see that they had then a hand-some balance in hand. We had been there; had consulted with the medical gentleman, secretary, and some of the members, and ascertained that the association gave satisfaction to all parties; and it accomplishes all that is stated in our handbills. Another object of the handbills was to ascertain to a certainty whether a sufficient number of members could be obtained to justify us in engaging a medical gentleman; and if the directors had not been satisfied, they would not have advertised for one. As far as our experience and knowledge go, such a thing as friendly societies failing to meet the claims of their medical adviser is unknown. The other strictures have certainly some weight as *a priori* argument, but facts are decidedly against them. When new clubs are formed, the general, almost universal, rule in our district is, that at some time after their formation, the services of a medical gentleman are engaged without any examination; afterwards candidates have to be examined. When a member of any society changes his medical man, he does so without examination. When associations like ours are formed, no examination is required; from those who join afterwards it is. We have a slight suspicion that any medical man would find it a little inconvenient to examine between two thousand and three thousand members in a few days, and attend to his other professional duties as well. The names of the managers will appear in due time and form, according to the custom of similar associations, printed with the report and statement of accounts; before that time it would be a waste of time and money to print them. I am directed to say that the managers will feel a pleasure in forwarding you their names if you desire it; but having held their meetings for eleven months, and being well known at Redditch, they cannot see that such a course could serve any useful purpose. It may be a misfortune that they are not "high-class"; but the societies they represent have always met their medical engagements, and will not enter into one with the gentleman they may appoint without giving him a satisfactory guarantee.

Trusting you will insert this in your next issue, and thereby remove the erroneous impressions the article would convey, I am, Sir, your obedient servant,

WILLIAM ASTON, Secretary to Association.

Redditch, Feb. 5th, 1875.

MR. SYMPSON.—The famous epigram on George the Third's physicians is an example of the advantage of rhyme; the wit lying in the metrical form, and in the form only.

"The King employed three doctors daily—
Willis, Heberden, and Baillie—
All exceedingly skilful men;
Baillie, Willis, Heberden;
But doubtful which most sure to kill is
Baillie, Heberden, or Willis.

CLUB-PAYMENTS.

SIR,—I am glad to see the letter of Dr. Fox in the JOURNAL of Saturday last, drawing attention to the inability of the medical men at Trowbridge to carry an advance in club-payments. We have a professional brother in this neighbourhood, whose antecedents, I believe, date from Trowbridge, who is a hindrance to our obtaining a better payment. The West Somerset Branch has lately considered the question of club payments, and has decided that 2s. per annum should be the minimum. Acting on this, my friend Mr. Nash and I addressed a joint letter to the medical men of the neighbourhood, asking them to help us in enforcing it. All but one of those addressed replied in most favourable terms. That one not only neglected to reply, but we were so surprised to find our club-members were made aware of our contemplated action by some of them informing us that we were going to resign unless we obtained the advance, and that he had offered to take them at the old rate. At the next quarterly meeting of our club, a copy of our letter was sent by him, with an offer of his services. With such professional men about us, we are powerless, and must go on at 7 d. a member per quarter, or retire in favour of our opponent. Surely the matter lies with ourselves; and, as long as we are willing to make ourselves so cheap, the public will take every advantage of us.

I am, Sir, your obedient servant,

HUGH P. OLIVEY.

North Curry, Taunton, February 10th, 1875.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

CONVALESCENT HOSPITALS FOR SCARLATINA AND OTHER INFECTIOUS DISEASES.

SIR,—Allow me to offer a few remarks on the establishment of hospitals for infectious diseases. From what I observe, compulsory measures are unpalatable to the public, and it would be deemed harsh to remove sick children from their homes. It certainly would afflict me to have my children taken away, though they might be ill of scarlatina or variola. If hospitals be built for infectious diseases, there should be no compulsion employed in filling them. It appears to me that seclusion for long periods in convalescent establishments would be much better calculated to limit the spread of scarlatina, because it is during the period of convalescence that individual's move about freely, shedding the cuticle, and poisoning every place to which they may go; and parents would readily consent to the removal of their children to such establishments. With convalescent hospitals, and with parochial or district disinfecting houses for the purification of bedding and garments, scarlatina and variola would become manageable.—I am, Sir, your obedient servant,
Rochester, Feb. 6th, 1875. FREDERICK J. BROWN, M.D.

SIR.—Would any of your correspondents who are connected with Foresters' clubs kindly inform me if it is their custom to charge a fee for the examination of candidates prior to admission? I am, etc., H. P. OLIVEY.
North Curry, Taunton, February 10th, 1875.

THE GRESHAM LECTURES.

SIR.—Your correspondent "Civis Londinensis", in drawing attention to my Gresham Lecture on Catching Cold, holds me responsible for a report of it which appeared in one of the daily papers. It is my duty, as Gresham Professor, to give such lectures on medicine as can be "understood of the people". The lectures are freely open to the public. Newspaper reporters are, therefore, at liberty to publish any part which they may think suited to their readers; and a single sentence has more than once been taken as a text for a newspaper article. It has thus come about that, in the notices of my recent lecture in the daily papers, the theoretical and scientific portions have been omitted, and the more practical points have been enlarged upon, without those careful directions as to the discriminating use of drugs and other remedial means which I always deem it necessary to give. Your correspondent remarks, "The Gresham Lectures used to be dignified, able productions, delivered in Latin." He is mistaken if he supposes they were ever delivered in Latin alone. When this was the language employed by men of science, it was the will of the founder that lectures should be delivered in English also. There can be no loss of dignity in explaining the principles of science in the Queen's English. In the attempt to lessen the ignorance which prevails as to the structure and functions of the body in health and disease, and the broad principles of hygiene and therapeutics, I venture to think that I am consulting the spirit of Sir Thomas Gresham's will, as well as the spirit of the age; while the large audiences that assemble to hear the English lectures sufficiently indicate that they are appreciated by the citizens of London. I am, etc., E. SMYTH THOMPSON.
February 10th, 1875.

MEDICAL DEGREES AND TITLES.

SIR.—Judging from the tenor of the correspondence which has been carried on for some time past in the columns of the BRITISH MEDICAL JOURNAL on the above subject, I do not think that the profession is capable of treating the question of medical titles impartially; and I am the more inclined to adhere to this conclusion when I reflect on the conduct of the London College of Physicians some years ago. This body could not decide whether their Licentiates were physicians or not, and they submitted the question to Sir Rounell Palmer, who decided that their Licentiates were physicians. There is yet, however, another question to be considered—viz., whether Licentiates are entitled to the prefix of "Dr."; and I can see no means by which this can be settled conclusively, except by submitting the question to the most eminent counsel in the three divisions of the kingdom. For this purpose, it would be necessary for those Licentiates who take any interest in the matter, to form a committee to prepare a case for submission to three of our best lawyers, and to accept the decision, whatever that might be—defraying the expenses, of course, by subscription, towards which the writer of this letter would be glad to subscribe a couple of guineas.

So far as I can discern, a physician is decidedly entitled to the prefix of Dr., and, in assuming it, does not, in my opinion, violate the provisions of the Medical Act. At the same time, I believe that the several bodies who first instituted the Licentiatehip did not intend the Doctorate to be extended to them. It is all very well for medical authorities to assert that they never intended their Licentiates to assume the Doctorate; at the same time, they willingly seek the aid of the law in determining questions of internal administration for them. If, therefore, they believe in the law when it "suits their book", they must also believe in it when it happens to be inconvenient for them. It is not the fault of Licentiates that there should be so much confusion about medical titles. To illustrate this more fully, I may observe that there are at present four grades of physicians—viz., the Licentiate, the Member, the Fellow, and the M.D. Now, to my mind it seems strange that if the public have a guarantee that the Licentiate is skilled in physic, there should be any use for the other three. Would it not be much better to make the supposed higher grades honorary titles? or, better still, to knock them all into one, rendering them only available to those who had done something towards the advancement of science?

Again, there is a notion prevalent that the Doctorate is much coveted by physicians. This I do not believe, as a rule; and when it is coveted, it is in self-defence. The general practitioner often finds by experience, when it is too late, that, however much his services may be appreciated, he sometimes meets with disappointment when the public show a preference for the man who is in possession of most letters. Here is where the shoe really pinches. The M.D. who can use the prefix "Dr.", confidently expects the public to consider him an abler man than his neighbour who can only aspire to "Mr."; and the latter is jealous, especially when he is doubly qualified, that he is struggling under a disadvantage; for how can he display his skill if it be prejudged to be inferior to that of another equally untried? I once lost an appointment worth £800 a year through not being M.D.; and when I practised in England, I found it an intolerable nuisance to be without the L.S.A., which in that country, ten years ago, seemed to be the most important qualification. If there were but one qualification all this injustice would cease, and the most deserving men would be more likely to get the best appointments. The profession itself is also much to blame in causing discontent. If those at the head of the profession were to speak to and address their constituents

as "Surgeon"—, in contradistinction to "Dr. —", the public would not be so ready to remark, as has often been done in my presence, "Oh, he is only a 'Mr.'; he is not a Doctor at all."

The gentleman who asked if he were a "tinker", spoiled his letter by doing so; and your *Maidstone* correspondent erred in wishing things to remain as they are. This is bad policy; and if he had not probably made some good local hit, he would find that "without a solid independence no man can be happy, or even honest." To your correspondent "M.D. Edin.", who has forgotten his "Latin", and would "require brushing up" in other matters, I would say that, on his own showing, there is *prima facie* evidence that the M.D. degree of some of our most famous Universities is no guarantee that the holders thereof are men of great learning, but rather substantiates the fact, that the majority of their alumni forget most of that which they did know.—I have the honour to be, sir, your obedient servant,
January 1875. SCOTUS.

SIR,—Touching the question of medical titles, which have been discussed in your *JOURNAL* lately, I beg to quote a case illustrating the injustice of a medical practitioner styling himself "Dr." on his door, he being L.R.C.P. Edin., 1850. On a tablet erected in the public street, to be read by all, his name appears with the initials M.D. after it, thus giving to the public that he is not only Dr., but also M.D. I shall leave the profession to form an opinion of this flagrant case of—to say the least of it—gross misrepresentation; and remain, sir, yours obediently,
January 1875. M.B. & C.M. Edin.

SIR,—A letter in the *JOURNAL* of the 16th instant, by "An Associate of Twenty-five years' Standing", concerning the M.D., merits the *purchased honour*; and for one who writes as well as he does, to suppose the honour is not always purchased, as well as every other medical or surgical qualification, is rather curious; but perhaps he means obtained *merely* by purchase, as the F.R.C.S. is by old surgeons. Ten years ago I desired to dispense with dispensing, and cast about me for an M.D. To me, in active practice, nothing British was to be got, so I sought foreign aid. I wrote to Erlangen, received the following reply, with which I complied.

"Erlangen, April 25th, 1864.
"Sir,—The alone sure course which you must follow, in order to become Doctor of Medicine of our University in the alone quite honorable and valuable mode, is to pay a visit to Erlangen, and to undergo a just examination, after having produced authentic proofs of medical and general respectability. Your medical diplomas and any other testimonials at every time and completed in 13 days; moreover, a treatise on any medical subject in manuscript is desired. The fees amount only £20 sterling.—Faithfully yours, Dr. J. M. LEVOLDT, Dean of the Faculty of Medicine."

My examiners were six in number, the professors at that time of the requisite subjects. The examination extended over three days, and I obtained the "purchased honour".—Yours, etc., M.D. ERLANGEN, M.R.C.S. & L.S.A.

SIR,—It will really be a relief when this useless controversy is settled, or when at least you come to the conclusion to refuse the admission to your columns of any further expression of opinion on the subject. The only matter for congratulation connected with the affair is, that such nonsense is not paraded before the public eye, but is confined to a professional paper; otherwise, the object that all should have at heart—the raising of our common profession to a higher level, socially and otherwise, than it occupies at present, and the making of ourselves more worthy of it—would certainly not be furthered by the present *infil*; and, after all, one will ask, *Cui bono*? Does any one imagine that a L.R.C.P. will not call himself Dr. if he prefer it (many do not). He, however, considers himself entitled to do so, legally and otherwise; so does his College, and states so. What does it, therefore, matter if M.D. think otherwise? All men in the profession know exactly the value of each title and degree; and it provokes a smile to hear a common platform claimed for such widely different qualifications as the London, Oxford, Cambridge, and Dublin degrees on the one hand, and the Aberdeen, St. Andrew's, and Glasgow on the other. We can only presume that the M.D. who informed us the other day that he was entitled by his degree to be considered a "professor or teacher", has suffered in consequence of "too much learning". Before he can impress other men with the great importance which he attaches to the letters M.D., he must induce his brethren to remove them from their shop-windows, as it ill comports with men of such high pretensions to be engaged in trade. He will then be doing some real service to his profession, which I think would probably be questionable should he betake himself to profession duties.—I am, etc.,
February 1875. A MEMBER.

SIR,—With your permission, I would place the "titles" first, because it is evident, from the tone assumed by the majority of your correspondents, that ambition is the foundation, and pride the fabric, of this fanciful controversy. Put away with both, and at the footstool of calm judgment let the matter be viewed. Let antiquity and our hoary-headed sires speak while the children sit still and learn; learn in particular that to be an M.D. is one thing, but to be worthy of it is another. I fear with the elasticity of the times there is growing an equally elastic state of conscience, and an enervated state of intellect that has become eloquent under the guise of words—resplendent bubbles and commonplace wit. I presume the fact of antiquity rapidly disappearing before endless innovations is but a significant sign and alarming indication, in this our day, of wholesale departure from first principles. Who and what was St. Luke? I wonder if the principles of Messrs. Mill and Bradlaugh are yet as rampant amongst the members of the medical profession as the flippant assumption of titles on the one hand, and the arrogant possession of them on the other. If so, my question is needless, since it will be demanded, "Prove that ever such a man existed!" Nevertheless, for one believe, upon the highest authority, that there lived such a man, and further, that he was a physician, who, judging by his writings, was equal to, if not excelling, in mental capabilities, quick perception, and knowledge of human nature in general, the teachers and exemplars of medicine and divinity in the present day. Yet where did he matriculate? where his Alma Mater? and what the qualifications entitling him to practise? Anyhow, two things are clear from his case; that the title of physician has the ring and approval of antiquity, and that the title was not indiscriminately conferred—hence to the present day we have the "consulting-physician" as the public ideal of the learned, the experienced, and the good. Physician, therefore, in the abstract, implies more than a mere physician's qualification; and as a man must be a physician before he can be called a consulting-physician, and cannot be a physician without the learning and experience of patient observation, it is clear that titles are mere legal plumes—"bones of contention", as we see at present. It is fair, however, to suppose that the various titles now in use signify more than an empty sound; but it is decidedly unfair to argue that the haughty M.D. has either antiquity or learning to put him above a real physician, whose name implies his calling, and is full of honour and dignity—so full,

indeed, that I am surprised that he should lay claim to the somewhat rough-and-ready, but most meaningless and indefinite, term "Dr." Let us cultivate the true qualifications, therefore, and leave the public to call us what they like; and surely my brother will be gracious enough to recognise in me the former qualification, whilst if my superior knowledge of the arts and sciences merit for me a special title, he will be only too glad to profit by my experience therein, as I, no doubt, will profit by his larger experience in the art of healing.

Finally, and in a word, we want to hear less of titles and more of experience; and let the man who is physician in reality as well as in name (if he boast at all), boast of antiquity, charity, experience, learning, and veneration; and let him who swaggers under the—shall I say matrimonial ensign, or gaudy legal plume called M.D.?—boast, not so much of his school and university, as of the stern fact that he "heareth not the root, but the root him".

I enclose my card, and beg to remain, sir, your humble servant, MEDICUS.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Gazette; The Western Daily Press; The Manchester Guardian; The Ulster Advertiser; The Sussex Coast Mercury; The Broad Arrow; The Surrey Advertiser; The Bedale and Northallerton Times; The Hackney Express; The Liverpool Porcupine; The Scotsman; The Liverpool Mercury; The Glasgow Herald; The Stroud News and Gloucestershire Advertiser; The Bradford Observer; The Morpeth Herald; The Portsmouth Times; The Western Daily Press; The York Herald; The Sheffield Evening Star; The Brighton Guardian; The Sussex Daily News; The Wrexham Advertiser; The Newton Directory; The Sussex Coast News; The Berkshire Chronicle; The Hull News; The Southern Times; The Worthing Intelligence; The Hampshire Telegraph and Sussex Chronicle; The Sheffield Daily Telegraph; The Hereford Times; The High Peak News; The Brighton Daily News; The Bath Argus; The Pembroke Herald; The West Briton and Cornwall Advertiser; The Glasgow Herald; The British Mail; The Indian Medical Gazette; The West Country Lantern; The Ripon Gazette; The Airdrie Advertiser; The Manchester Courier; The Wolverhampton Chronicle; The Cork Constitution; The Sheffield and Rotherham Independent; The Liverpool Daily Post; The Redruth Times; etc.

COMMUNICATIONS, LETTERS, ETC. have been received from:—

Dr. Lauder Brunton, London; Dr. Smart, Haslar; Mr. W. F. Clarke, London; Dr. Markheim, London; Dr. Spencer, Clifton; Dr. T. C. Brown, London; Dr. James Donaldson, Glasgow; Dr. R. J. Lee, London; Mr. Evan Powell, Sunny Bridge, Brecon; Dr. D. T. T. Maunsell, Dublin; Dr. T. W. Grimshaw, Dublin; Mr. Neville Hart, London; Dr. F. T. Bond, Gloucester; Dr. J. W. Langmore, London; Dr. J. J. Charles, Belfast; Mr. I. Harrinson, Reading; Dr. Finlayson, Glasgow; Dr. J. M. Fothergill, London; Dr. Joseph Bell, Edinburgh; Dr. J. W. Moore, Dublin; Dr. George Johnson, London; Dr. Bradbury, Cambridge; Mr. T. H. Bartlett, Birmingham; Dr. Edis, London; Mr. T. Holmes, London; Dr. B. W. Morris, Brighton; Mr. Slack, Peterborough; Mr. Nettleship, London; Dr. J. W. Black, London; Dr. A. Fraser, Aberdeen; Dr. Falconer, Bath; Dr. J. Batty Tuke, Edinburgh; etc.

BOOKS, ETC., RECEIVED.

Cremation of the Dead. By W. Fessie, C.E. London: Smith, Elder, and Co. 1875.
Commentary on the British Pharmacopoeia. By W. G. Smith, M.D. London: Smith, Elder, and Co. 1874.
The Curative Effects of Baths and Waters. By Dr. Braun. Abridged Translation by H. Weber, M.D. London: Smith, Elder, and Co. 1874.

AN ADDRESS

ON THE

ETIOLOGY OF ACUTE SPECIFIC DISEASES.

*Delivered before the Clinical Society of London, on Friday,
February 12th, 1875.*

By SIR WILLIAM JENNER, BART., K.C.B., M.D., F.R.S.,

Physician in Ordinary to Her Majesty the Queen, and to H.R.H. the Prince of Wales; Physician to University College Hospital; President of the Society; etc.

GENTLEMEN,—Nothing but a most imperative duty could have prevented me from presiding at the last meeting of the Society. Now that I have the pleasure of taking this chair, I desire first to thank you for the honour you did me when you elected me your President. The Presidentship of the Clinical Society is, in my estimation, one of the highest honours that can be conferred on a physician. It was not until after I had accepted the nomination that I realised the fact that former Presidents had inaugurated the Session with an address; and, when I realised this, conscious of my own inability for properly discharging that duty, I felt misgivings as to the wisdom of having accepted the honour. I trust to your kindness to-night to overlook my deficiencies.

The Clinical Society was founded for "the cultivation and promotion of the study of practical medicine and surgery by the collection of the reports of cases, especially of such as bear upon undetermined questions in pathology or therapeutics"—a very wide field of inquiry; for, as far as my knowledge extends, there is no disease, even the most common, respecting which there are not undetermined questions in regard to its pathology and its treatment. There is not a single disease, however common, respecting which it can be said that its etiology is quite determined; and no report of a case can clinically be complete, the etiology of which is not given. There is no disease, respecting which it can be said that the symptoms which mark its very outset and its course, the symptoms which mark its decline, the symptoms which enable us to tell at the outset what will be its course, the effects which follow after the disease has apparently ended, and the influence which pre-existing conditions of health and disease, as well as that which drugs and other therapeutic agents exert on its progress, termination, and sequelæ are perfectly known. Regarding all these points in every disease, even the most common, there are undetermined questions. Many of these questions admit of answer; many of them ought to be answered; and that many of them are not answered, is, I think, discreditable to us as a profession. Medicine has made very great progress; and, if it were my aim to-night to illustrate that progress, I could find ample material for doing so. Medicine has made great progress; few sciences have made more; but, still, in regard of every disease, in reference to every one of the points I have mentioned, we are wanting facts—facts which could and ought to be supplied; and it is in the hope that my words may stimulate the Fellows of the Society to assist in the collection of these facts, that I would to-night illustrate our present deficiencies rather than dwell on our past performances.

Let me illustrate my meaning first by a reference to one or two points in regard of the etiology of a class of the commonest and best studied of acute diseases—I mean the acute specific diseases. In reference to these, one may say that they are all contagious; that is, from some part of the sick something is given off which can, when properly applied, excite the same disease in another, and which can excite no other disease. Little is known of what this *something* is; and yet it is most important for the prevention, and even for the treatment, of these diseases that we should know. Little is known of those conditions of system which render this something sufficient to the production of the disease in one person, while in another it is inert. For example, at a certain time one of these diseases is what is called epidemic. Scarcely a person who has not had it and is exposed to the emanations of the sick escapes taking it. On another occasion, the disease is not epidemic, and then many, with equal degrees of exposure, escape. Measles was not epidemic in a certain town at the time to which I am about to refer. A child came from school, having just recovered from measles.

The family consisted of sixteen persons, eight of whom were children, and one only took the disease. Another family at the same period contained nine children. One contracted measles at school, and returned home; only two of the eight suffered; all of them being freely exposed to the poison.

Among the questions which are asked and ought to be answered are: What are the conditions which favour outbreaks of epidemics? Are they atmospheric? And, if so, are they conditions existing at the time of the outbreak, or are they conditions dependent on pre-existing atmospheric conditions? Or are the conditions that favour the outbreak of an epidemic states of health of the population, the consequence of co-existing or pre-existing atmospheric or other conditions? Although some of these questions, it may be thought, refer to subjects outside the scope of clinical medicine, some certainly are within that scope.

As a good illustration of the influence of pre-existing individual conditions in regard of susceptibility to contagious poisons, I may refer to the well known fact of the intimate relation between the state of the system left after measles and the susceptibility to the poison of whooping-cough. The individual who has just suffered from one of these diseases is, as is well known, prone in a remarkable degree to take the other. That is to say, after the occurrence in an individual of one or other of these diseases, a very small dose of the poison of the other disease is sufficient to produce the development of that disease. And, as bearing on this subject, I may refer to Dr. Aitken's paper on the influence of the previous residence in Bulgaria on the health of the troops in the Crimea.

One point respecting the etiology of these acute diseases has recently been brought before the profession and the public in rather strong language, the question: namely, whether these diseases can arise spontaneously. A controversy has lately—I was going to say raged—about the mode of origin of typhoid fever, and it well illustrates at the same time our ignorance, the difficulty of ascertaining facts, and the danger of reasoning upon insufficient facts, on an insufficient number of facts, on insufficiently observed facts, and the unwisdom of drawing general conclusions from facts which bear only on one side of a question. It is said by some that typhoid fever is undoubtedly contagious; it is said that, being contagious, it can never originate *de novo*. That is to say, as it can be proved in some cases to have its origin in the entrance of the emanations of the sick into the previously supposed healthy, it can never arise in any other way. On the other side, while admitting that the disease may be spread by the emanations from those suffering from the disease, it is said that the admixture of sewage decomposing animal excreta, with fluids used for drinking purposes, although no typhoid excreta are present, will produce typhoid fever *de novo*; that is to say, in those that drink the fluid; and it is said that the inhalation of sewer-gas is sufficient itself to produce in persons previously healthy typhoid fever *de novo*. Before considering briefly some of the arguments that may be adduced in support of any of these statements, I may say that, to my mind, from the known facts, the question should be held to be still *sub judice*, and that it is only to be solved by the combined efforts of those who can investigate the origin of typhoid fever when it occurs as an epidemic or in the form of severe local outbreak, and of those practitioners who, being engaged in private practice in country districts, can examine into and report on the solitary cases occurring under circumstances favourable for excluding fallacies. It is rarely that solitary cases can be satisfactorily investigated in towns; and it is because this important question can only thus be solved, that I desire to impress on the members of this Society the importance of reporting every solitary case which can throw light on the question. We have already had, and, no doubt, shall have, many more ably described epidemics, severe local outbreaks, and local outbreaks on a smaller scale. We shall have these traced to their origin by men of the highest order of intellect and the largest possible experience. We have had such reported now in numerous cases; and, as the points that still require elucidating in these local outbreaks become better known, these men will be sure to discover the missing links; but no investigation of such local outbreaks can answer completely the question which I say is still *sub judice*; and, therefore it is, that those who see the solitary cases must report their personal experience, if we are to have the question definitely and indisputably answered. I know how difficult it is for men engaged in large private practice to hunt out all the facts bearing on the origin of a single case; but, when they consider of what immense importance it is to the public and to the scientific advancement of our profession, I trust that some of them will be willing to sacrifice a little time for the general good.

One general assumption made by those who advocate the sole origin of typhoid fever by contagion, requires special consideration. This general assumption is this, that no admittedly contagious disease ever originates in any other way than by contact with the emanations from the sick; and therefore that typhoid fever, spreading by

contagion—a mode of spread which I think is now pretty generally admitted by all those who have studied the question—can be spread in no other way. This general assumption is as yet wanting in such proof as conveys conviction to my mind; and I cannot help thinking that it is wanting in such proof as should convey conviction to any unprejudiced mind, accustomed to investigate questions of this nature. My own prejudices are greatly in favour of the specific origin of this in common with all contagious diseases. I have long advocated the specific differences, and held that each had its specific cause; that is, a cause which is unable to produce any other acute specific disease; and if each could, in every case, be referred to emanations from those previously sick of the same disease, it would greatly strengthen the general views I have long held and advocated. I am prejudiced, therefore, in favour of this opinion. I hope it is true; but then I must say that, at this moment, the weight of evidence and of argument is rather on the other side. When an admittedly contagious disease is epidemic, it is evident that facts to elucidate the question of its spontaneous origin cannot be collected. There is so much of the special poison in the locality, that no one can be sure that he has not in some way exposed himself to its influence. But, when the disease is no longer epidemic, when isolated cases occur, then it is that, if a disease never originated *de novo*, we ought—I will not say in every case, but in the majority of cases—if we inquire carefully, to be able to trace back the apparently spontaneous case to its source. Of small-pox, the most contagious of all diseases, I do not hesitate to say, notwithstanding Dr. Budd's assertion to the contrary, that the large majority of solitary cases can be traced with due care each to its probable source; and when a case has been imported into a locality previously free from the disease, new cases almost invariably spring up in its vicinity; so that the contagious origin is proved first, by tracing the case to its source; and, secondly, by the new cases which spring up from the first isolated case. Small-pox is eminently contagious; and not only so, but from the vast proportion of instances in which we can trace isolated cases to their source, from the rarity of the cases in which it is impossible to trace the probable origin to contagion, we may fairly conclude that small-pox never originates *de novo*.

But now let us pass to the other end of the scale of undoubtedly contagious diseases, namely, diphtheria and erysipelas. I mean erysipelas of the head and face, the acute specific disease of which erysipelatos inflammation of the throat and face, beginning usually from the bridge of the nose, is the anatomical character; a disease which is attended with definite symptoms, sometimes before the eruption, and sometimes accompanying the eruption, as are the acute specific diseases. Of the contagious nature of diphtheria and erysipelas, I think there can be no more doubt than there is of the contagious nature of small-pox. They are not so contagious; but they are both contagious. They are not as contagious, for it is more common for the healthy, exposed to the emanations from the sick, to escape from these diseases, than it is for those exposed to the effluvia of small-pox to escape small-pox. Now, while in regard of small-pox, it is the exception not to be able to trace the source of the contagion; in diphtheria, it is comparatively rarely that the first case, even of several, can be traced back to contagion. In regard to erysipelas of the head and face also, undoubtedly, as I say, contagious, it is the exception to be able to trace the case to contagion. Now, it is evident that the more contagious a disease—that is, the less the quantity of poison needed, the shorter the time of exposure to the poison necessary, and the less preparation required in the system of the individual receiving the poison—the less frequently, *a priori*, should we expect that the disease should be traced back to its primary source; while, with the diseases of this class which are the least contagious, which require for their spread a longer exposure or more decided doses of the poison, or the administration of the poison in a particular way by a special channel, we should expect that, in every new case—if every new case were due to exposure to emanations from the sick of the same disease—we should the more easily be able to trace them to their original source, the more easily should the parent case be discoverable. But we know that it is not so; for those which are the most contagious are the most commonly traceable to their origin, and those which are the least contagious can the least frequently be proved to have originated in contagion; and we are driven thus, it seems to me, towards the opinion that erysipelas frequently, and diphtheria not uncommonly, originate *de novo*.

Typhoid fever, like diphtheria and erysipelas, holds a low position in regard to its contagious quality. It rarely spreads, excepting when the excreta from the sick are administered by a particular channel. I have never known a case removed from its place of origin to give the disease to the inmates of a house into which it was removed, unless there were a communication between the source of the drinking fluid and the bowel excreta of the patient. Last autumn, ten young men, students at

Oxford, went to stay in the same house in Cornwall. After a short residence, each returned to his own house, and seven sickened with typhoid fever. These young men evidently contracted the disease in the house in Cornwall. A highly contagious disease, in the ordinary sense of the word, ought to have been the focus from which other cases should have sprung. Had eight young men suffering from small-pox or scarlet fever been distributed into eight houses, I do not hesitate to say that some of the inmates of those houses would have suffered from small-pox or scarlet fever, as the case might be. I have never known a case of small-pox admitted by accident into the hospital to which I have the honour of being physician, without some one or more persons contracting the disease. When formerly I was physician to the Fever Hospital, I took my clinical class to the hospital for the purpose of showing them fever in its various stages on a large scale. Now, while I never knew a student to contract typhoid fever there, it so happened that on one occasion there was a case of small-pox in an outer ward of the hospital—a ward of very large dimensions. While no student took, on any occasion, either typhoid or typhus fever, one on that special occasion took small-pox; and on another occasion, there being several cases of scarlet fever in the ward, one took scarlet fever. But in the case of these young men from Oxford, who were distributed into separate houses, not one conveyed the disease to any inmate of the house to which he was removed. That typhoid fever can spread from one person to another without the swallowing of the excreta, if the person be exposed to the concentrated emanations from the sick frequently and for a considerable time, there can be no doubt. I have twice known students contract the disease who were diligently taking the temperature of the patients sick of typhoid fever, before the registering thermometer was in use, and therefore were obliged on each occasion to put the head many times daily into the bed of the patient. And I doubt not that most of those present could add to the number of these young martyrs to science.

Still typhoid fever has such limited power of propagating itself that the poison must be in large doses, or long breathed, or taken into the stomach, to produce the disease. Therefore I say that the disease ought, in the majority of cases, especially in country places and isolated houses, to be able to be traced to its source, if the source be in every case the excreta or emanations of those suffering from the disease. But, in fact, its origin has not hitherto been able to be traced to pre-existing cases in a very large proportion of the solitary cases observed. But not only do numerous cases occur in which typhoid fever is not traceable to exposure to emanations or excreta from the sick with typhoid fever—that is, to contagion—but there are a sufficient number of cases to render it probable that the admixture of sewage not typhoid with drinking water may produce the disease *de novo*; and most of us must have met with cases in which the breathing of greatly diluted sewer-gas continuously for some time, especially at night, has seemed to be able to produce typhoid fever *de novo*. But new cases, sceptically scrutinised and carefully recorded, are required to settle this question. It is only in exceptional instances that cases free from all possible, at least from all probable, sources of error can come under notice; and such cases can only be seen, as I have said, in private practice, especially country practice; and it is for this reason that I especially dwell on the subject to-night, my desire being to urge the careful observation and reporting of these isolated cases.

The following case serves to illustrate the difficulties which beset inquiries such as this. A young lady was under my care with typhoid fever. She had been for some months an invalid, and was so placed that all probable sources of the communication of the disease from the outside could be excluded. She resided in a completely detached villa. She was confined to her own room. There were few inmates of the house, and those were entirely devoted to her service. She had lived in the house about two years, and during that time no one had suffered from typhoid fever. On the floor on which she slept and lived at the time, there was a water-closet well ventilated, used only by two or three persons in perfect health. Now, this young lady was the only person who never left the floor, that is to say, she was day and night breathing air on this floor. A sewer-gas odour was detected, and, on taking up the floor, it was found that there was a crack in the soil-pipe of the water-closet just below the seat, in such a position that the gas escaping from the soil-pipe at this part would find its way between the joints and the boards of the floor, and thus pass into the rooms on this floor. It is true this young lady had received a few visitors in her bedroom, and it is possible, it may be said, that some of them were the subjects of typhoid fever. But the persons who visited her were all well known, and there was no ground for thinking that any one of them suffered before or after from typhoid fever. Again, the drains of the house opened into the drain of the town, on the outskirts of which the villa is situated; but, then, the drains were trapped

and the traps were new and efficient. It is only by the multiplication of solitary cases that proof on the one side or on the other can be obtained.

With reference to these three contagious diseases which are unable to be traced, in many cases, to pre-existing cases of the same disease, that is, typhoid fever, diphtheria, and erysipelas, there are three points worthy of notice. First, they are more liable than the most contagious, as small-pox, measles, and scarlet fever, to recur in the same individual. Secondly, when not referable to contagion, each is pretty constantly referred to a particular and the same cause; for example, diphtheria to exposure to cold; erysipelas to exposure to cold when the exposed person was depressed from fatigue, mental or moral causes, fasting, etc.; typhoid fever to foul gaseous emanations or contaminated water. Thirdly, certain primary constitutions seem more prone than others to suffer from these less contagious diseases. All people seem to be susceptible to scarlet fever, to measles, and small-pox, when exposed to the poisons, but these three diseases occur in certain constitutions especially. We are all acquainted, I am sure, with families that exhibit these proclivities. I have known diphtheria, for example, occur in four members of a family at long intervals of time, and in localities widely separated—one in London, one at Brighton, one at Scarborough, and one at some other place in the country. Now, when we consider the infrequency, comparatively speaking, of diphtheria, such a fact as this shows on the part of the members of the family a great primary constitutional proclivity to the disease. I have known six out of seven males of a family to suffer from typhoid fever, no two of the cases occurring within less than two years' interval, and no two at localities within less than fifty miles of each other, while in the same family one only of the same number of females suffered from typhoid fever. Here, again, there must have been a great proclivity to typhoid fever on the part of the males of the family. I do not say, nor do I think, that the arguments and facts able to be adduced in favour of the origin *de novo* of the contagious diseases are conclusive; but I do say, and I do maintain, that they are strong enough to make us pause before we accept the theory advocated by Dr. Wm. Budd, and to which Professor Tyndall has lent the weight of his great name, a weight which would, however, be greater on the point in question, if he had himself studied the subject on which he has, I am sorry to say, addressed the public in a strain calculated to check unprejudiced individual inquiry.

What I have said on the etiology of the acute specific diseases shows how much has yet to be proved, how hard is the work to be performed ere the opinions entertained on the subject can be converted into knowledge. I will not dwell longer on the etiology of the acute specific diseases, but I must allude briefly to the condition of the individual which precedes the establishment, in many cases, of chronic organic disease. We are apt to pay too little attention, to attribute too little importance to the general—to use a very barbarous expression—"out-of-healthiness"—which is so common in previously healthy persons from overwork, from anxiety, from overfeeding, from overstimulation short of so-called intemperance, from want of food, from bad air, from deficiency of exercise, from deficiency of stimulus, to "out of healthiness" in which the patient refuses to admit that he is ill, although he is a little, as he says, out of sorts, and only seeks advice because his friends notice that he does not look well and urge him to consult a physician. This condition cannot be studied in hospitals. Those only who are engaged in family practice can trace the origin, can watch the course, can estimate the effects of this condition in all its bearings. For myself, I have been long satisfied that a very large proportion of the subjects of organic diseases, tubercular, malignant, and degenerative, using those words in their widest sense, are mistaken when they attribute the symptoms of imperfect health, from which they have long suffered, to incipient local disease, and for not detecting which they too often blame their first medical attendant. The deteriorated general nutrition to which I have referred as mere "out-of-healthiness" was the cause of their sense of want of perfect health; and, ultimately, this imperfect general nutrition of every part of the body culminated in the extreme malnutrition of that part or organ which natural constitution or accidental circumstance had rendered less able to resist organic change.

As to the symptoms which mark the very outset of a disease, in illustration of my position that there is not a disease respecting the symptoms at the outset of which we are not wanting recorded facts, I may refer again to that much studied disease, typhoid fever. In Wunderlich's excellent work, is the following statement. "We may exclude typhoid fever when, between the fourth and sixth day, in a child or adult under middle age, the temperature never reaches 103.1°; and indeed, he says, if it fail to do so two or three times. It is impossible not to see that this conclusion is based, as are other of his statements, on cases admitted into hospital; and every one who has enjoyed much experience

in private practice would, I think, be disposed to temper this law with so many exceptions that, as a law, it would hardly exist; yet, in proof of the existence of these numerous exceptions, recorded facts are wanting.

With reference to our lack of recorded facts as to the course of common diseases, I shall only mention one disease concerning which I thought two facts quite certain; but, on talking to others, I heard doubts expressed as to the truth of those facts, and I soon found that the observations on record were not detailed with sufficient precision to justify me in drawing the conclusion which, if the supposed facts be real facts, flows from them.

Does emaciation make rapid or steady advance when an external organ, unneeded for life or health, as the breast, is the seat of scirrhus cancer, when the appetite is good, and there is neither ulceration nor discharge? If it be that this steady loss of flesh occurs when the breast is the subject of scirrhus cancer, does it take place without any elevation of temperature? Had there been recorded facts to answer these two questions in the affirmative, then it seemed to me that this important conclusion would follow. In the process of nutrition, there are three factors—namely, the cells of the body generally, the nerves that regulate their functions, and the material out of which tissue is to be formed. It is clear that atrophy of the body generally, like atrophy of a part, may be due either to excess of waste, or to deficient supply of new material; but, if there be no elevation of temperature, there can be no rapid waste of the whole body; and, as we know that in cancer there is no disturbance of the nerve-function of the body generally, and as the cells of the body generally are healthy in structure, then we should have to hold that the emaciation must be due to the third factor in nutrition—namely, the blood. I mention all this, not as affording any clue to the pathology of cancer, which would be out of place here, but as illustrating the want of facts, of accurately observed and carefully recorded facts, in relation to the course of one of the commonest of diseases.

Time will not permit me even briefly to illustrate our lack of knowledge in regard to the other headings to which I have referred; but, before concluding, I must direct your attention to two or three points bearing on our knowledge of the treatment of disease. It does seem to me to be again, I may say, discreditable to us as a profession, that so common diseases as rheumatism and whooping-cough—each, so far as we know, uniform in its pathology—should have for their cure so many drugs. For the good service able to be rendered by each of these drugs, men of high position, of great power of observation, of unquestioned honesty of purpose, have vouched in the most emphatic manner; and yet no one of these drugs is found by the profession, speaking generally, to yield unequivocally favourable results; while the precise recorded observations of one of the distinguished men who have filled this chair, and his colleague Dr. Sutton, have thrown so much doubt on the value of some of the remedies which have enjoyed the highest reputation for the cure of rheumatism, that a re-examination of all these so-called curative remedies is imperatively called for. The difficulties in the way of advances in true therapeutic knowledge are very great; but are the difficulties insuperable which stop the way to our ascertaining the real value of the cures for acute rheumatism or for whooping-cough? Could not an unprejudiced examination of the effects of all the remedies hitherto propounded by men of repute, purporting to have tangible evidence in their favour for acute rheumatism and for whooping-cough, be undertaken on a large and decisive scale? There are two kinds of evidence to be adduced in favour of the value of any drug on the course and termination of a disease. One is the evidence afforded by individual cases observed separately, all the special points of which can be weighed at the bedside by the practitioner—weighed, it is true, rapidly, and perhaps roughly, but still weighed; for example, the age, the sex, the habit, the constitution, the presence or absence of complication, of concurrent or pre-existing ailments, of all the surroundings, etc. Every remedy must be, as a final court of appeal, put through this trial; and, if time be given to dispel the illusions of fashion, and to allow the weight of great names to be reduced to their true standard, it is pretty certain that the verdict is correct.

What may be called incomplete diagnosis has often led to erroneous generalisation in regard to treatment, identity of symptoms being confounded with identity of pathological conditions. The late Sir Benjamin Brodie had great confidence in the bichloride of mercury in the treatment of paraplegia; and he, and others following his example, prescribed it indiscriminately in cases of paraplegia. He saw it cure syphilitic paraplegia; and, not knowing that the particular case he was treating was syphilitic in nature, he regarded bichloride of mercury as the remedy for every case of loss of power in the lower extremities. Other members of the profession tried the effect of bichloride of mercury in paraplegia; and, if it happened that they gave it in two or three

cases of syphilitic paraplegia, they too expressed the greatest confidence in bichloride of mercury as a cure for paraplegia. But others happened to give it in succession to two or three cases not syphilitic in nature, and they declared it to be useless, or worse than useless, as a cure for paraplegia.

One mode, then, of estimating the value of therapeutic agents, may be called the individual; and, in testing the value of particular modes of treatment, members of this Society generally may assist. The other mode of estimating the value of therapeutic agents may be called the analytical; that is to say, we test the worth of the drugs by the analysis of a large number of carefully observed and recorded cases. For cases thus collected to be compared, they must be numerous enough to afford a sufficient number more or less identical in regard of age, etc. Researches of this kind can only be conducted in hospitals; and I think, for the purpose of collecting such cases in sufficient number, for the purpose of directing attention to special comparable facts, committees might be formed from members of this Society; and, were this done with due care, every member of the Society might aid in obtaining valuable, because real, therapeutic knowledge. And the testing clinically the value of the several remedies proposed by great authorities for the cure of acute rheumatism and of whooping-cough seem to me to be objects worthy of such a committee, and the questions involved seem to me to be those that such a committee might in time definitely answer.

Excuse me yet a little while, whilst I speak of the treatment of a special class of diseases. When any acute specific disease is epidemic, the educated public call loudly for a cure, and too often, I think, the members of our profession call out as loudly "Eureka!" Now, to me it seems that there are no grounds for expecting that a cure will ever be found for diseases of this class; that is to say, for expecting that a drug or medicinal agent will be discovered capable of arresting the progress of the organic changes which, set in motion by a special cause, following each other in definite and ascertained order, constitute what we call an acute specific disease; for, in place of being diseased actions, these several organic changes, the evidence of which we call symptoms, are, so far as our present knowledge extends, processes, the first of which being called into action by some external cause (for example, the poison of the disease), are essential for the restoration of the intimate organic changes to the order and intensity which constitute health. I may illustrate my meaning thus. Each of these diseases may be likened to a single fit of ague. We administer drugs to prevent the recurrence of the fit, but we do not cure the fit itself. The cold stage having commenced and attained a certain intensity, the hot and sweating stages are essential to the restoration of the balance of health. So with small-pox. By vaccination we prevent its occurrence; but, when the first of the phenomena—which, following each other in certain and definite order, constitute small-pox—occurs, we know that there is no road to health but by the sequence of changes, the symptoms of which mark the several stages of the disease; and it is to my mind very questionable whether, if it were possible by administration of a drug to arrest the essential changes which constitute any one of these stages, health would be the result. What is true of small-pox in this particular, seems to me to be equally true of all acute specific diseases; and when I read the list of cures for cholera which swarm in the columns of the press at the first intimation of an epidemic of that disease, I should smile, did I not know that a column of cures for cholera in a leading newspaper may be the death-warrant of numbers. Although the science of medicine can never hope for a cure for any one of these diseases, it can prevent death from all, and it is time that the public, and not the profession only, had correctly appreciated what medicine can and what it cannot be expected to do, in this class of diseases. Nor would medicine as a practical science fail in public estimation, or the physician be less highly esteemed, were the public instructed in the matter rationally. At one time, the chemist was valued especially, because it was supposed that, by his aid, base metals could be transmuted into gold—"base", as they were foolishly called; and day and night he sought for that "power of projection", as it was called, by which the transmutation could be at once effected. Faith in this transmutation, faith in the discovery of this powder of projection is exploded; but is the chemist less highly valued, his aid less earnestly sought? No. The work he can do is of more worth than the work it was fancied he could do. So with the physician; he cannot transmute by a special drug the sequence of processes which we call an attack of cholera into the sequence of processes which we call health, any more than the chemist can transmute iron into gold. The "certain cure for cholera" and the "powder of projection" of the alchemist are alike apocryphal; the dreams of a pre-scientific age, or the base attempts of charlatans and quacks to prey on those whose minds are yet in the prehistoric stage of development; that is to say, on the ignorant and the credulous. The public must learn that the

true, the real in regard of the relation of medicine to these diseases is as different and as superior to the fancied as is chemistry to alchemy, or natural science to the black art. Medicine teaches us how to prevent in many of the acute specific diseases the first of those processes, the sum and sequence of which constitute the disease; and, when the first of that sequence has commenced, the physician, though he must reprobate the folly of those who cry out for a drug which will stay the sequence of processes which are in reality steps to health, does not stand helplessly by and leave the patient to his fate; but, by the judicious application of the rules of art, so moderates the necessary disturbances of formation, that they shall eventuate, when the last of the series of restorative processes is over, in health in place of death. The physician in such cases may be likened to the physicist who, although he cannot prevent the discharge from the electric-laden cloud, can yet save the threatened tower by conducting the lightning-flash harmlessly to the earth.

LECTURE

ON

COMPARATIVE PHARMACOLOGY AND THERAPEUTICS.

Being part of an Address delivered at the Manchester Club of Aberdeen Medical Graduates.

By JAMES ROSS, M.D., Waterfoot, near Manchester.

THE physician has to do primarily with functions, and, secondarily, with structure; and it may be thought that molecular physics, including chemistry, has made such rapid strides of late years that it will afford, along with physiology, as secure a basis for his treatment as molar physics along with morphology does for that of the surgeon. But this is not the case. The effects produced upon organisms of all kinds by bodies in mass, is much better ascertained than those produced by the molecules of substances circulating in the fluids of the body. And this lack of knowledge of the effects produced by the molecules of substances which gain entrance into the circulation, constitutes the greatest gap in our knowledge of the sciences which form the immediate basis of treatment. But even this gap is being rapidly filled up. I am not an old member of the profession, yet my text-book on the subject which treats of drugs and of their actions, which was a closely printed octavo volume of about 800 pages, and which was full of all sorts of information respecting the drugs themselves, gave only the most scanty information with regard to their action upon the body. The only information which it contained with regard to the action of such a commonly used and useful drug as bicarbonate of potash was, that it was "antacid, antilithic, diuretic, and resolvent", and it gave no fuller information with regard to the action of any other drug. Things are somewhat mended since then. We have such works on *Materia Medica* as that of Nothnagel in Germany, Rabuteau in France, Dr. Wood, jun., in America, Dr. Sydney Kinger, and a first instalment of a work by Dr. Charles Phillips in this country. I have not yet seen Dr. Wood's work, but I am told that it is very accurate, and contains a vast amount of information respecting the action of drugs. I can, however, speak from a personal acquaintance of the other works which I have mentioned, and I must say that each and all of them are immensely superior to the treatises which were in existence during my student days. But, notwithstanding these works, much requires to be done before a scientific basis is given to drug-treatment. In every department of knowledge, the systematic application of the comparative method is that which has given the most valuable results to the scientific workers of the present day. The science of comparative anatomy, or more correctly of comparative morphology, has been constituted within the memories of many living; while the foundations of comparative physiology, comparative psychology, and comparative philology, have been laid by our own contemporaries; and even now comparative theology is pressing itself upon our notice. And, to give a scientific basis to drug treatment, we must found the science of comparative pharmacology. We want to discover a general body of formulæ, which shall be true not simply respecting the action of drugs upon this or upon that organism, but respecting their action upon all organisms whatsoever. And if our facts were fitly arranged for the application of the comparative method, many such formulæ could be readily obtained; indeed, a glimpse may be got of a few of these formulæ even with our present arrangement of the facts. Take, for instance, any one agent, such as ethyl-alcohol, and compare its action upon different organisms. Alcohol

checks the movements of protozoa like the amœbæ, and kills them without producing any other symptom. Leaving out of account its action upon vegetables, not because it is important, but because so little is known respecting the action of drugs generally upon them, let us administer it to an animal a little higher in the scale than the protozoa. When it is given to one of the articulata, for instance, there are no marked contrasts between the action it produces upon various parts of the body. It kills by an almost simultaneous suspension of all the functions. When, however, it is administered to one of the vertebrata, the effects produced, both simultaneous and successive, are very varied and multiplied, and the multiplication and variety of effects reaches its height in man. The effects produced upon the human organism need not be described in detail. The experiments which we ourselves are carrying on with this agent at present, sufficiently demonstrate that its effects upon us are more multiplied and varied, in one word, more heterogeneous than the simple homogeneous effect it produces upon amœbæ; although I make no doubt that, if we carry our experiments sufficiently far, alcohol can check our movements as it does those of the protozoa. But as we proceed from the lower to the higher organisms, not only do the effects produced become more heterogeneous but they become more special. This is as true of other agents as of alcohol; but, in the case of the latter, the special effects produced upon the nervous system are so pronounced as to obscure its other effects. To account for this speciality of effect, it has been assumed, that alcohol has a special affinity for nervous tissue, but there is no reason to make this assumption. Alcohol is a very indifferent substance, having chemical affinities of narrow range; and, since it enters into no strong chemical unions without the body, there is no reason to believe that it will exhibit strong affinities within the body. And, moreover, it checks the amœboid movements of the white blood-corpuscles and the movements of the cilia of the bronchial mucous membrane, showing that much of its action is independent of the nervous system. Various reasons might be given to explain why an agent, which acts indifferently upon all tissues, should yet produce a more special action upon one part of the body than upon another; but a few of these must suffice. It is probable that no agent can act until it comes into contact with the protoplasm of the tissues; and, in some tissue, the intercellular substance is so dense, that even a diffusible agent like alcohol would take a long time in gaining access to the protoplasm, while it would gain ready access to the protoplasm of such a delicate structure as that of the nervous tissue. And, from the nature of the function of nervous tissue, a very slight interference with its structure will produce a large and manifest effect upon function: while a very considerable interference with the structure of passive tissues, like bone and tendon, and even most mucous membranes, will produce a very inappreciable effect. And, again, the more freely an organ is supplied with blood, the greater the proportion in which an indifferent substance, like alcohol, circulating in the blood, will be supplied to it; hence an organ performing a very active function will have a greater amount supplied to it than one performing a less active function. These considerations show that, as we proceed from the lower organisms to the higher, not only does the action of an agent become more heterogeneous, but also more special, even if the agent itself is a perfectly indifferent substance, acting in a similar manner upon all living tissues whatsoever.

I have already spoken of the value of embryological studies, and I will now show that such studies tend to throw a considerable amount of light upon the action of medicines. The embryo-cell is almost homogeneous in form and chemical composition, but, when developmental changes begin after fertilisation, this condition soon gives place to a heterogeneous arrangement of parts, which is accompanied by a heterogeneous disposition of chemical elements. Some of the salts of lime become deposited in one part, those of iron in another, and phosphorus in a third. There is no occasion to believe that each of these elements had a special affinity for the tissue on which it has become deposited. The specialisation of structure in each of these tissues has been preceded and caused by specialisation of function. When, however, a specialisation of function has produced a modification of structure, a capacity for performing the function becomes developed in the tissue, and this reacts upon the function, and renders a further specialisation of it possible, which, in its turn, produces a further modification of structure. And, accompanying this modification of tissue, there is a corresponding modification of chemical constitution or of composition, or of both; the differentiation of chemical composition being slight when the differentiation of function is slight, and profound when the differentiation of function is great. There can be no doubt that the deposition of phosphorus, and of the salts of lime, iron, and other elements, which are not found in ordinary albumen, was a necessary condition of the differentiations which result from the action and reaction between structure and function; but it is not necessary for us to assume

that each of these elements had originally a special affinity for the tissue in which it is found. When, however, differentiations of chemical composition have once been produced, they will lead to specialisations of chemical action, if heterogeneous agents are introduced into the blood. Like will gather to like, and when an agent cannot find its like, it will select that part of the body which is most similar to it.* In this way we find that the compounds of the chemical agents, which have massive atoms, act principally upon the dense parts of the body; whilst those of the least massive atoms, act upon the parts of the body which have a delicate structure, such as muscle and brain, and probably also upon the blood. We know that the salts of iodine, mercury, silver, lead, and of the metals generally, act upon the bones, tendons, and cellular tissue; those of potash and soda upon muscle; those of carbon and the gaseous elements, principally upon nervous tissue. This also explains why the compounds of the elements, having massive atoms, are eliminated by the bowels, those of the elements, with atoms of medium mass, by the kidneys, and volatile substances principally by the lungs, and partly by the skin.

The embryological law, which was first formulated by Von Baer, may be modified so as to be applicable to the action of medicines. The law is that, in its earliest stage, every organism has the greatest number of characters, in common with all other organisms, in their earliest stages; that, at a stage somewhat later, its structure is like the structures displayed at corresponding phases, by a less extensive multitude of organisms; that, at each subsequent stage, traits are acquired which successively distinguish the developing embryo from groups of embryo which it still resembles; and that thus the class of similar forms is finally narrowed to the species of which it is a member.† This law, which is true of structures, is equally true of functions, and the likenesses and unlikenesses which it asserts respecting the structures of organisms during their development, are also true respecting the reactions of these organisms to the action of drugs. The law may be modified in the following way. The action of any drug upon an organism in its earliest stage is similar to its action upon all other organisms in their earliest stages; its action upon the same organ at a somewhat later stage of development, is similar to that which it produces at corresponding phases upon a less extensive multitude of organisms; at each subsequent stage, peculiarities of action become manifest, which successively distinguish that produced upon the developing embryo from that produced upon groups of embryo, which it still resembles; and, lastly, the action produced upon the organism displays peculiarities which narrow the similarity to that produced upon the species of which it is a member.

Our facts might also be arranged so as to facilitate a comparison of the effects produced not by one agent upon different organisms, but by different agents upon one organism. The embryological law, already noticed, taught us that the actions produced upon different organisms are similar when the organisms are similar, less similar when the fundamental likenesses between the organisms are less, and only remotely similar when the likenesses between the organisms are small. We now come to the obverse of this law. The actions produced upon

* When I gave expression to this law, I was not then aware that M. Cere of Strasbourg had anticipated me by upwards of thirty years. He draws the following conclusions from his experiments. 1. That volatile substances introduced into the system have a tendency to be eliminated by those organs which, in a physiological state, secrete gases or vapours—the lung and skin, for example. 2. That substances which contain principles the same as those which naturally form part of a secretion are eliminated by the organs which furnish this secretion. 3. That substances which enter into the composition of an organ, when given as medicines, are carried to that organ. 4. That among the substances which do not naturally enter into the composition of the solids or fluids of the animal system, there are some whose action is of what may be called their general chemical character; thus acid substances are eliminated by acid secretions. (See *American Journal of Medical Science*, April 1843, p. 438.)

† Nor was I aware then that M. Gubler has recently enunciated a similar law. He maintains that—1. Substances, when absorbed, tend towards their similars or analogues; 2. When a substance cannot meet with its similar or analogue, it must be eliminated; 3. It is eliminated by the channel in which it meets with similar bodies. (See the *London Medical Record*, December 23rd, 1874.)

‡ In the text, I have availed myself of Mr. Herbert Spencer's expression of this law (*Principles of Biology*, vol. i, p. 442). Von Baer's law is the following:

"1. Dass das Gemeinsame einer grössern Thiergruppe sich früher im Embryo bildet, als das Besondere.

"2. Aus dem Allgemeinen der Formverhältnisse bildet sich das weniger Allgemeine und so fort, bis endlich das Specielle auftritt.

"3. Jeder Embryo einer bestimmten Thierform, anstatt die andern bestimmten Formen zu durchlaufen, scheidet sich vielmehr von ihnen.

"4. Im Grunde ist also nie der Embryo einer höhern Thierform einer andern Thierform gleich, sondern nur seinem Embryo." (*Über Fortpflanzungsgeschichte der Thiere, Beobachtung und Reflexion*, von Dr. Karl Ernst v. Baer, Erster Theil, 1828, s. 224.)

These laws, however, when separated from the discussion which precedes and follows their enunciation in Von Baer's work, do not give a complete embodiment to the conceptions intended to be conveyed; but the laws are of more than passing interest, since they are the germs from which sprang much of what is characteristic of the philosophy of Mr. Herbert Spencer.

similar organisms by different agents, are similar when the agents themselves are similar in chemical and physical properties, and the likenesses between the actions become less and less as the agents become removed from each other in their fundamental properties.*

At the meeting of the British Medical Association this year, at Norwich, I proposed, in a paper "On the Action of Mercury," two laws of the action of medicines. The first is that, other things being equal, the more massive the atom of the element the more definite and local will be the action of its compounds; and the second that, other things being equal, the greater the molecular mobility of an agent, the more general and diffused will be its action.† These laws frequently coincide, yet the one is not the converse of the other. Mercury, for instance, is an element with massive atoms, hence the action of its compound should be local and specific; but it possesses great molecular mobility, since it volatilises at ordinary temperatures, hence it should exercise a wide and diffused action upon an organism. Reference to observed facts shows that, although the action of mercurial compounds is specific, yet it is of wide extent. In the light of these laws, the experiments of my friend and old fellow-student Dr. McKendrick of Edinburgh, in association with Mr. Dewar, upon the chinoline and pyridine series of bases, possess the utmost significance. These compounds could, at one time, only be obtained by distilling natural alkaloids, such as strychnine and quinine, with caustic potash; but chemists now form them from coal-tar.

Mr. Dewar, who is the chemist, forms the compound, and submits it to Dr. McKendrick, who determines its physiological action. Chinoline, which has a composition of $C^9 H^7 N$, and boiling point of 238° , has an action somewhat similar to that of chloral; but, as we ascend in the scale, the action upon the sensory part of the encephalon is becoming less marked, and that upon the motor centres more manifest, until the higher members of the series ($C^{16} H^{11} N$, with boiling point above 300°) produce death by convulsions and subsequent paralysis, not unlike the action of strychnine. As the molecule of the agents is becoming more massive, the action is becoming more special and local; the higher part of the brain being left unaffected at first, then the lower ganglia, until at last we have almost the pure action on the cord itself.

It would be interesting and instructive to make comparative experiments upon the action of the alcohols to see if they conform to a similar law.‡ The little we know of the action of different alcohols gives indications that such is the case.

The action of methyl is more diffusible than that of ethyl-alcohol. Nothing much is known respecting the action of propyl-alcohol; but Scotchmen know that when a man gets drunk upon new raw whiskey, which contains a considerable percentage of amyl-alcohol, the effect differs considerably from that of drunkenness from more or less pure ethyl-alcohol. There is less blunting of the intellectual faculties, and a more profound disturbance of the lower emotions, such as rage and jealousy, and I think I am right in saying that a poisonous quantity of such a compound is apt to produce convulsions. It is very probable that the difference which Dr. Magnan of Paris has shown to exist between the action of absinthe and that of ordinary spirits is one of this kind, and depending upon the presence in absinthe of an alcohol with a higher chemical composition than that of ethyl-alcohol. A comparison of the action of the various alcohols suggests to the mind the operation of another law. The monatomic saturated alcohols are poisons, the diatomic alcohols or glycols are less poisonous, the triatomic alcohols or glycerines have a still less effect, and when we come to the tetratomic, pentatomic, and hexatomic alcohols, we obtain substances which are either inert or are foods. This may be an example of the law that, other things being equal, the more heterogeneous a substance is to the body, the greater will be its effect. The hexatomic alcohols or glucosides are homogeneous with the body, and, therefore, will act as foods; while the monatomic alcohols are both physically and chemically more heterogeneous to the body than any of the intermediate alcohols. The reason why the hexatomic alcohols act as foods while the alcohols with saturated radicals act as poisons, is probably that the former are less stable than the latter, and consequently undergo with readiness transformations within the body, whereby force of some kind is evolved. A more

or less parallel fact may be noticed with respect to inorganic substances. The elements which are classed as irritants are, as a rule, either univalent or bivalent; while the substances called tonics are generally either trivalent or some higher degree of atomicity. This law has a sufficient number of exceptions to show that the irritant or tonic properties must depend upon other conditions than the atomicity of the agents. Another law is that, other things being equal, the greater the molecular mobility of an agent, the sooner it gains entrance into the body through the absorbing surfaces, and the sooner it is eliminated. This law explains why nitrous oxide gas acts more rapidly, but more evanescently, than ether, and other than chloroform, and chloroform than chloral. Closely related to, although not the converse of, this law is the one, that the compounds of the elements with massive atoms are relatively long in gaining entrance into the circulation through the absorbing surfaces, and are correspondingly long in being eliminated; and when the agents form, like the metallic salts, stable compounds with albumen, the length of time before they are eliminated is much increased. Another law is that, other things being equal, in binary compounds both elements are represented in the effect produced, but the action of the heavier atomized element will predominate. Take, for instance, chloride of potassium, bromide of potassium, and iodide of potassium. In the first, the action of both elements is represented, but that of the potassium predominates; in the second, the action of the bromine predominates, but when an animal is poisoned by bromide of potassium, the action of a potash salt upon the heart is apparent; while, in the third, the action of the iodine largely predominates. The action of this law may be traced through compounds of a higher grade than the binary. When, however, an agent produces a very energetic effect, such as hydrocyanic acid, it makes its influence predominate even in composition with the more massive atomized elements. We can promise a rich harvest to any one who will have the patience to differentiate by experiment the physiological action of the various chemical groups of organic compounds, and who will then contrast with each other the actions of the groups themselves; such as that of the hydro-carbons, alcohols, ethers, acids, aldehydes, ketones, amines, and amides, and passing through the remarkable bases which I have already mentioned—the chinoline and pyridine series—to the natural alkaloids.

These laws belong to a general science of pharmacology. They are as true of the action of medicines upon all organisms, especially all animal organisms, as they are of their action upon man. They are, however, too remote from practice to be of much immediate use. More specific laws must be discovered before a great effect is produced upon practice; and, to do this, we must proceed in a systematic manner with the arrangement of our facts. We must first of all possess a descriptive pharmacology, which must be freed as much as possible from all hypothesis. I think myself that, if we were to arrange all the facts known respecting the action of medicines upon different organisms in tables similar to the plan adopted by Mr. Herbert Spencer for arranging sociological facts, a great deal might be done in a few years to reduce the actions of medicines to a complete systematic form, which would afford a good scientific basis for the treatment of disease by drugs.

I must now bring these remarks to a close. I have already trespassed much too long upon your patience; but, before sitting down, I will endeavour to enforce one or two practical rules with regard to teaching. It is evident that no student can acquire a real knowledge of all the subjects I have mentioned in four years. In making a choice of subjects for his study, we must fall back upon the rule I have already laid down. He must have a minute and accurate knowledge of the subjects which immediately underlie practice; and the teachers of the subjects which bear only remotely upon practice should be careful not to burden the student's mind with too many details. It is perfectly possible for a student to have a good grasp of the fundamental principles of botany, zoology, and even chemistry, without the mind being burdened by a too minute recital of facts. And, if this rule be necessary for the teacher, it is doubly necessary for the examiner. It would be a great pity to reject a student who is well qualified to make a sound practitioner because he cannot tell the natural family of the castor-oil plant.

The only other remark I would make with respect to teaching is, that the student should be brought as much as possible, and as early as possible, into contact with Nature for himself. He must be taught to be independent of teachers. A medical man is, before all, a man of action, and he should not be a passive recipient of the sayings and doings of others; but he should be encouraged to employ himself actively in the study of science. A man must first woo Nature before he endeavours to master her in her erring moods. Hence, a student should spend much of his time in the dissecting-room, the museum, the chemical and physiological laboratory, and, above all, in the dispensary and the medical and surgical wards and *post mortem* room of a good

* In connection with this law, I ought to mention the names of Drs. W. H. Broadbent, Crum Brown, and Thomas Fraser, in this country, and Jolyet and Cahours on the Continent. (See *London Medical Record*, Dec. 2, 1874, p. 809.)

† Rabuteau has recently enunciated the law, that metals are more active, physiologically, according as their atomic weights are higher or their specific heats are lower. The monatomic metalloids are governed by a law which is the reverse of this. The metals rubidium, tungsten, and molybdenum are exceptions to the law. The differences between this law and mine are sufficiently obvious not to require pointing out. (*London Medical Record*, Dec. 2, 1874, p. 874.)

‡ Dr. Benjamin Ward Richardson has drawn attention to the fact, that the number of atoms of carbon contained in an alcohol appears to serve as an index to its activity, as may be seen by comparing the respective activities of ethyl and amyl alcohol. (See *London Medical Record*, December 23rd, p. 810.)

hospital. And you will permit me to say that no university medical school in the present day can overlook, without committing suicide, the necessity of establishing a physiological laboratory, and including pathological anatomy in its official curriculum of study.

ON THE CONDITIONS OF EFFICIENT DISINFECTION AND ON SOME NEW FORMS OF DISINFECTANT.

By FRANCIS T. BOND, M.D., B.A.Lond., Medical Officer of Health, Gloucestershire Combined Sanitary District.

THERE are probably few subjects connected with practical hygiene with regard to which more confusion exists in the minds both of the medical profession and the public, than that of disinfection; there are certainly no sanitary appliances upon which more money is wasted, or more confidence falsely placed, than on the so-called disinfectants which are generally employed. Antiseption, or the arrest of putrefaction—a purely temporary process, and even simple deodorisation, or the chemical neutralisation of its results, are confounded with biolysis, or the permanent destruction of life. Nay, more; the mere fact that certain bodies emit powerful odours is assumed to indicate that those odours themselves possess the power of arresting the spread of infection. Unfortunately, the facility with which a little cheap and very disagreeably smelling powder can be scattered about an infected house, or over the mouth of a drain, is too apt to generate, in the minds both of sanitary authorities and of private individuals, an unfounded confidence in its virtues, which too often leads to a disregard of other measures which are of far more real importance, thus producing results from which the community at large suffer. For this state of things medical men are in a large degree responsible. A disinfectant, especially one which has a good strong smell, like a drug with a good strong taste, is an ally which practitioners often have not the courage to discard, even though they may have strong doubts as to the value of its aid. It represents to the patient an amount of potentiality which is measured by the effect it produces on his organs of sense, and offers to him a sort of material guarantee that "something is being done". Under these circumstances it is, perhaps, not strange that so offensive a body as carbolic acid should still enjoy a large popularity, in spite of the incontestable evidence which has been adduced as to its untrustworthiness as a disinfectant in the way in which it is mostly used; nor, on the other hand, that a liquid, whose deodorant action is so evident both to the eye and nose, as is that of a solution of the alkaline permanganates, should have acquired a reputation as a true disinfectant, to which it has no claims whatever. Of the immense importance of really efficient disinfection, where it is practicable, no one can have any doubt; and in proportion as this conviction is strong, so should be the effort to use, for the purpose, those agencies whose action shows them to be most reliable.

To employ worthless or even feeble instruments, where more trenchant ones are at our service, is to needlessly play into the hands of disease; nor do we less so, when we attempt to use even effective weapons for a service which they cannot perform. If disinfection be worth undertaking at all, it should be done as thoroughly as is practicable; anything like half measures, where whole ones can be conveniently employed, should be actively discouraged, and any attempt to accomplish impossibilities should be rigorously eschewed. In order to have a clear idea of what can and what cannot be done in this direction, it will be well to briefly consider what objects we should have in view when we practise the process of disinfection.

We have the strongest possible reason for believing that certain specific diseases are produced mainly, if not exclusively, by the introduction from without into the bodies of healthy persons of material particles communicated from the bodies of persons suffering under those diseases. The object of all efficient disinfection is, if possible, to destroy the vitality of these particles altogether, or, if it fail in this, to so effectually neutralise it that it shall be arrested sufficiently long to allow these sources of infection to be removed by natural (atmospheric dispersion) or artificial (water-carriage or absorption into the earth) means from the immediate vicinity of the healthy. Whether these particles be of the nature of germs, having an independent life of their own, and developing like seeds or ova when introduced into an appropriate soil; or whether they be merely fragments of diseased tissue or portions of diseased secretions, which act upon the healthy

fluids of the body in a somewhat analogous way to that of a piece of rennet on milk; or whether, lastly, they be independent, free-moving organisms (contagion-bacteria of Traube), generated either spontaneously or by implantation in the fluids of the sick person, which possess the power of making their way into the fluids of the healthy, and there, by their multiplication, setting up the specific disease, we cannot positively say. Probably all of these hypotheses have a justification in fact, each one of them representing the mode of diffusion of one or more special forms of infectious disease. What is equally probable is that some, if not all, of these material sources of infection partake more or less intimately in their composition of that albuminoid character which all primitive forms of life exhibit. And what is still more probable is that, if these sources of infection be independent organisms, they grow and multiply most readily in albuminoid fluids, and that, even where these organisms are not themselves directly destroyed, their vitality and activity are more or less completely arrested by agents, which render albumen physiologically inert, and cut off, as it were, the sources of their subsistence. In the words of Shylock:

"We take their house when we do take the prop.
That doth sustain their house; we take their life
When we do take the means whereby they live."

If, then, we seek to destroy the physiological activity of these infectious particles, there are only two ways in which we can hope to do so. The first of these is, by the employment of agents which effectually destroy all organic bodies; and, in so doing destroy, of course, their reproductive activity. Such agents are heat, and rapidly acting corrosive chemical agents, such as the strong mineral acids. Heat in the dry form can only be conveniently employed for disinfecting purposes by the aid of appliances specially constructed for the purpose, at some considerable expense, and with certain requisite precautions. It therefore is only fitted for use through the interposition of sanitary authorities or public institutions. But heat in the liquid form, in the shape of boiling water, can be readily applied to all washable articles, and if not absolutely destructive of all sources of infection, which is, perhaps, open to doubt, is at any rate a valuable adjunct to any form of chemical disinfection. The corrosive mineral acids, though available in certain limited conditions, as in hospitals and other similar institutions where they can be employed with due precaution for the disinfection of alvine evacuations, are, for obvious reasons, out of the question for general disinfecting purposes; and, though less rapidly, corrosive agents, such as chlorine and sulphurous acid, will probably, if applied for a sufficient length of time and in sufficient quantities, produce the same effect, there are practical difficulties in the way of doing so efficiently, which make them of little or no use, except perhaps when applied in a concentrated gaseous form, for disinfecting articles of clothing or other objects in a closed chamber. As ordinarily employed, in the liquid form (chloride of lime and calcic bisulphite), these agents are merely deodorants, or, at best, antiseptics, which rapidly lose their power, partly from oxydation and partly from volatilisation.

The second method consists in the use of agents which chemically coagulate albumen, and thus render it physiologically inert. The action of such agents is probably twofold: firstly, attacking such elementary organisms as are of an albuminoid character, and gradually destroying them; and, secondly, in so affecting albuminoid liquids, that they become unsuitable as a pabulum for such organisms. It is in this way, probably, that the high antiseptic power of albuminous coagulants is to be explained. As a matter of fact, it will be found that those bodies which have the highest power of preventing putrefaction, and with it the development of free-moving organisms, are mostly energetic coagulators of albumen. It is true, that the power of antiseption is not confined to coagulants, many organic bodies which exercise no apparent influence on albumen possessing it. But, taking the chief metallic salts which act as antiseptics, it will be found that their antiseptic and coagulant properties are closely proportionate.

Hence, then, it is before all things desirable, that any substance which is to be used for disinfecting purposes, should be an energetic coagulator of albumen, not only for the purpose of directly attacking infectious elements, but also of arresting putrefaction. But, though the effective coagulation of albumen is a first requisite in a perfect disinfectant; and, though it would, probably, be sufficient if we had only to deal with the disinfection of organic compounds which had not entered into putrefactive or fermenting decomposition, as a matter of fact, most of the compounds to which disinfectants have to be applied have already advanced to this stage; and it is important, for several reasons, that the results of this process, in the shape of various gaseous products, should be neutralised. This deodorising part of the disinfecting process is essentially a chemical one, and the most efficient of all deodorisers is unquestionably ozone, from the rapidity with which it attacks one of the invariable constituents of all putrefactive emana-

tions, viz., hydrogen. Hence, all active ozonisers are active deodorants. A body may, however, act as a deodoriser without being an ozoniser at all; e.g., metallic salts by their action on sulphuretted hydrogen, and acids and acid salts by their action on ammonia. Looking at the various matters to which a general disinfectant may require to be applied, it will be found in practice desirable that it should have as it were a double deodorising power; one to act on the more purely organic results of decomposition, and the other on sulphuretted hydrogen. For the first of these purposes ozone is, in every way, the most appropriate agent, and it would, of course, be equally applicable for the second of the above objects were there not practical difficulties in the way of employing it in sufficient intensity. For the effect even of a very intense dose of ozone is very soon exhausted on any organic liquid, and the rapidity of this exhaustion is no guarantee of the permanency of the deodorant effect; since organic elements to be attacked by it need not be in a state of decomposition at all, but only in one of unstable equilibrium. Hence, in the use of an ozonising agent, such as the permanganate of potassium, upon a complex organic mass in a state of decomposition, like feces, the exhaustion of the disinfectant is complete at once, though the process of decomposition itself may not be even temporarily arrested. The process of disinfection is, therefore, under the different conditions in which it may be required, a complex one, and the results to be compassed are not to be obtained in the most satisfactory manner possible from any single agent. The prescription for a disinfectant, like that for a medicine, should be in most cases double, or even treble shotted, if it is to be effective under all circumstances. And even when we have carefully balanced its chemical ingredients with a view to their producing a maximum effect, we have not achieved the whole object in view; for, in addition to considerations of efficiency, are certain others of an economic and practical character which cannot be overlooked. It would not, probably, be difficult to name a dozen organic and inorganic bodies at least, which would be infallible disinfectants if they could be conveniently used, but which, either from their cost or on other grounds, are unavailable.

For these reasons, then, the composition of a disinfectant is a matter of some little difficulty. Its designer has to balance the greatest number of advantages against the least number of disadvantages, and the more completely he can do this, the more effectually will he attain the object he has in view. A few words will be sufficient to explain the practical conditions to be aimed at. In the first place, as those sources of infection which can be most readily dealt with are either presented to us in the liquid form, or can only be energetically attacked by liquid agents, our disinfectant should be either itself a liquid, or, if a solid, should be as largely soluble in water as possible. This condition indicates a fatal objection to the various forms of powders sold for disinfecting purposes, in which carbolic acid, itself an almost insoluble body, is combined with from eighty to ninety per cent. of entirely insoluble matter. Any one who will take the trouble to make a solution of these powders, and then to test the strength of that solution as an antiseptic, will soon convince himself of how little value it is. In the next place, for the reasons stated above, our disinfectant should act as energetically as possible upon albumen consistently with a due regard, amongst other things, for the economic conditions in which it is most likely to be required; e.g., its action over clothes, closet-fittings, etc. This consideration excludes such bodies as the permanganates from the list of effective disinfectants, however useful they may be as deodorants.* To trust to such agents alone as disinfectants in cases of infectious disease is like firing blank cartridge at a tiger.

It may be well here to advert to the idea which seems to prevail somewhat extensively, that carbolic acid is a powerful coagulator of albumen, and that it is upon this property that its antiseptic powers depend. Carbolic acid is, it is true, a fair albuminous coagulant, but it is only when it is brought in contact in mass with an albuminous structure, such as a mucous membrane, or a raw wound. When mixed with a solution of albumen, it is, in consequence of its slight solubility in water, an extremely feeble coagulant, as any one may easily satisfy himself by pouring some of the liquid acid into a solution of egg-albumen in water, or into blood serum. Even if violently agitated, so as to reduce the acid to an extreme state of comminution, coagulation is very imperfect, probably from each globule of the acid becoming at once coated with a pellicle of coagulated albumen, which prevents further action. If the antiseptic powers of carbolic acid are to be utilised at all (and for certain crude purposes it has some recommendations), it should be combined either with matters which are themselves soluble, or which will promote its solution, and which

will, so far as is practicable, themselves exercise some influence on organic decomposition.*

Having acquired these properties for our disinfectant, we have to a large extent gained others which are very desirable. For instance, as has been before remarked, we shall find that in proportion to its efficacy as an albuminous coagulant, will be its power as an antiseptic. By a judicious selection of a coagulant, we may also obtain a body which shall act upon sulphuretted hydrogen and ammonia, two of the most offensive results of organic decomposition. Most antiseptics are deodorants, though it may be doubted whether in some cases the deodorisation is not more apparent than real, in consequence of the strong odour of the disinfectant masking that of decomposition. Ozone, as has been above observed, is the most effective of all deodorants—hence it is very desirable that an ozoniser of some kind should be combined with our disinfectant. The influence of carbolic acid as a deodorant is possibly—in part, at least—due to its evolving ozone whilst itself is undergoing oxidation: that of chlorine is also partially attributable to the same cause, from its decomposing action on water, though also in a large degree to its direct effect on hydrogenous gases. It may also be assumed that it is desirable that the ozonising influence of our disinfectant should be capable of being exerted not only in solution, but by atmospheric diffusion: and for purposes of mere deodorisation this is, no doubt, important. It would appear that, practically, this object can be most readily attained by the use of certain organic bodies, which in the act of diffusing a volatile aroma, more or less actively evolve either ozone or peroxide of hydrogen (Schonbein's antozone). The use of such bodies for purposes of deodorisation is not to be confounded with any attempt at real atmospheric disinfection. Such an attempt is, I believe, impracticable by any such means. There are, however, three ways in which there is a possibility of achieving such a result: the first, and by far the most effective, is thorough ventilation, which, by sweeping into the outer air, and thus largely diluting, as it were, the infectious elements, reduces *pro tanto* the chances of their prejudicial action, and is probably as beneficial to the sick person as it is to the healthy around him; the second, which is much more problematical, is the diffusion through the infected atmosphere of a corrosive gas, such as sulphurous acid; the third is the diffusion, in the form of spray, of an efficient liquid disinfectant, by means of which the atmosphere may, as it were, be thoroughly washed out.

Of these three methods, the first is obviously the only one which can be practised whilst the sick person occupies the infected room; and it is, in my opinion, ample both then and after convalescence, if combined with careful dusting, washing, and, so far as is possible, liquid disinfection of all surfaces and articles in the infected room.† A good sulphuring effectually deodorises the offensive atmosphere and articles in a sick room, but it is very doubtful whether it does any more. Of how little value the vapour of carbolic acid is for antiseptic purposes is shown by the fact that the decomposition of meat or other readily putrefiable bodies, suspended in an atmosphere of it, is scarcely appreciably retarded.

With the view of ascertaining the best practicable combination for ordinary disinfecting purposes, I have for some time been engaged in a series of experiments on the value of various bodies for disinfection, as evidenced by their power of arresting putrefaction, of retarding the development of free-moving organisms, and of neutralising the results of decomposition. The details of these inquiries I hope to publish hereafter, when some of them, which are not yet quite completed, are finished. It will be sufficient to say that they are generally coincident with, and confirmatory of, the results arrived at by Dr. John Dougall of Glasgow,‡ in his lengthened and elaborate inquiries, and by Surgeon-Major O'Nial of the Army Medical Staff.§ The result of these experiments has led me to the conclusion that a combination of the aluminic and cupric sulphates with the potassic dichromate (producing in effect a potential cupric dichromate) possesses antiseptic powers of the highest degree, and is, at the same time, a most energetic coagulator of albumen, as well as a good deodorant, so far as sulphuretted hydrogen and ammonia are concerned. With this inorganic triad I further combine (mechanically) a small quantity of terebene (one of the isomers of oil of turpentine), a body which seems to have attracted little or no attention.¶ This body possesses remarkable deodorant properties which are apparently due to its being an active ozoniser, which latter property is of itself in all probability owing to terebene

* To use liquid carbolic acid in quantity, as is generally done, is absurd waste: nineteen-twentieths of the acid are entirely thrown away in consequence of its slight solubility in water (about three per cent.).

† I have saturated with sulphurous acid gas solutions of decomposing organic liquids teeming with bacteria and virulence, without apparently affecting them.

‡ On Putrefaction and Antiseptics, *Glasgow Medical Journal*, 1872-73; also paper read at Sanit Science Meeting, 1874.

§ *Army Medical Reports*, 1871.

¶ The so-called "terebene" of the shops is a very different body; and, instead of being a substitution compound, is only an oxydised product of oil of turpentine.

* It is scarcely necessary to say anything of the worthlessness of such salts as calcic and sodic chlorides. As disinfectants—even as antiseptics—their action is very feeble, compared with that of numerous other available agents.

being a body in a state of very unstable equilibrium, and very prone to oxydation. The odour of terebene is far from being disagreeable; in mass it is somewhat terebinthinous, though quite distinct from that of turpentine, and is generally said to smell like oil of thyme or oil of cinnamon; but, when diffused through the air, in which condition it probably soon passes into incipient oxydation, it has an aroma quite peculiar, and not at all unlike that of fresh pine-wood, of the odour of which wood it is not at all improbable that terebene is the cause. At any rate, terebene possesses the same powers in a very active degree; and that it evolves ozone or else peroxide of hydrogen, may be shown by its producing the characteristic effect on tincture of guaiacum and blood-solution.

It is not inappropriate, in connection with this fact, to note that attention has lately been drawn by several writers, especially by Dr. Day of Geelong, Australia, to the ozonising properties of pine-wood, and to its value as a material for the construction of hospitals for infectious disease. In fact, Dr. Day attributes to it disinfecting powers of a high order. That it possesses very efficient deodorising properties, is within the observation of any one who has noticed the effect which fresh pine sawdust has on offensive masses; but that it is in any true sense a disinfectant is, for the reasons given above, I think more than doubtful.

To the compound above described, I give the name of *cupralum*. For crude deodorising purposes, where the coarser results of decomposition, such as sulphuretted hydrogen and ammonia, have to be neutralised, I combine a mixture of the sulphates of iron and alumina, with a mixture of carbolic acid and terebene. To this compound, which will be found effective for a variety of purposes, such as the deodorisation of drains, cesspools, urinals, etc., I give the name *ferralum*.

THE TEMPERATURE OF PHTHISIS.

By C. THEODORE WILLIAMS, M.D., F.R.C.P.,

Physician to the Hospital for Consumption, Erompton.

THE questions put to me on the temperature of phthisis by Dr. Edward Mackey, in the last number of the JOURNAL (February 13th), are of such importance, that I lose no time in replying to them, although I could have wished for a still larger accumulation of material than my 104 cases before I laid down definite laws on the subject.

Dr. Mackey asks for a further expression of opinion from me on the average frequency and character of the cases where tubercle forms without any rise or fall of temperature, and quotes some of Dr. Ringer's propositions: viz.: 1. There is probably a daily elevation of temperature in all cases where a deposition of tubercle is taking place in any organ; 6. By means of temperature (rise), we can in many instances diagnose tubercularisation long before physical signs were sufficient; 8. It is probable that, by means of the temperature (non-rise), we can conclude that the deposition of tubercle has ceased.

Of my patients, twenty-six were active first stage cases, in which no cavities existed, or any supuration was proceeding, and the formation of tubercles was the only evident lesion. They thus, perhaps, afforded better opportunities of ascertaining the thermic phenomena accompanying tubercle formation than the more or less advanced cases to be found in a general hospital, and than Dr. Ringer's, in some of whom excavation had already taken place; for it is obviously of importance to exclude the phenomena of supuration as far as possible.

In seventeen of the above twenty-six, a rise of temperature accompanied the formation of tubercle; the rise took place in the afternoon, invariably subsided at night, and was followed by normal or subnormal morning temperature. In some, the rise preceded the physical signs, in others it did not. In nine of the above cases (more than one-third), no rise was perceptible, though it was carefully watched for, the observations, as Dr. Mackey must have seen from my paper, being taken very frequently. In five out of the nine, subnormal temperatures prevailed, yet here the process of tubercularisation was traced day by day and step by step with the stethoscope; of these cases, two are narrated in my paper, one in which development of tubercle took place, and the other where a distinct extension of the tubercle-formation was detected.

These patients presented no striking clinical features, and their cases afterwards followed the course of chronic phthisis. The amount of consolidation seemed to bear no relation to the temperature. Five of the nine had one lung affected; four had both lungs involved. In one, active tuberculosis was taking place in both lungs. Some of the patients belonged to that category of cases where the early symptoms are so often mistaken for those of bronchitis, the tuberculosis being accompanied by wheeze and sonorous rhonchus, with frothy expectoration. All doubt as to the presence of consumptive disease was set at rest by

the appearance of subclavicular or suprascapular dulness. Valuable evidence confirmatory of my cases, and exhibiting the frequency of low temperatures in early phthisis, will be found in Surgeon Nathaniel Alcock's very able essay on the Nature and Varieties of Destructive Lung-Disease included under the head of Pulmonary Consumption (*Army Medical Reports*, 1873). My large opportunities at the Brompton Hospital have enabled me to collect and analyse the greatest number (as far as I know) of temperature-records of phthisis; and I do not hesitate to affirm that their evidence is not in accordance with Dr. Ringer's first and eighth propositions, nor, again, with this paragraph: "Admitting an elevation of temperature in all cases of tuberculosis and catarrhal pneumonia, it follows that, if the temperature be normal, we may conclude the patient is free from these diseases." Dr. Ringer's cases were, I believe, fewer than my own, and by no means so free from complications; but I do not doubt that so competent an observer, if he had had the same field for watching early phthisis, would have arrived at much the same conclusions on this subject as myself.

The old idea, that the formation of tubercle is invariably accompanied by rise of temperature, is untenable; and the question arises, in cases where high temperature is present, whether it may not be caused by the presence of pneumonia set up by the tubercle rather than by the tuberculosis itself? If the whole temperature-course of phthisis, in all its forms and stages, be surveyed, it will be apparent that low temperatures are as much, if not more, a characteristic of the disease as high temperature; and, if Dr. Mackey require a temperature-test for tuberculosis, he will be more likely to find it in (1) the fall of temperature at night, (2) low records of the early morning; or, when a rise takes place, not in the fact of the rise, but in the period in which it takes place, viz., in the afternoon, and in the rapid fall of the temperature towards night.

As I have recently laid a considerable mass of evidence on the subject before the profession in my paper read at the Royal Medical and Chirurgical Society on January 26th, and as I am preparing another, dealing with the effects of various accompaniments of phthisis on the temperature, I will not trespass further on the space of the JOURNAL. The joint work on *Pulmonary Consumption* by my father and myself contains little mention of diagnosis by temperature; for, at the time of its publication, my results had not been obtained; but, in a future edition, the question will be duly discussed.

PRELIMINARY NOTICE OF EXPERIMENTS ON THE PHYSIOLOGICAL ACTION OF JABORANDI.

By J. N. LANGLEY, B.A., St. John's College, Cambridge.

DR. FOSTER, having received from Dr. Ringer, through Mr. Martindale, a small quantity of the alcoholic tincture and glycerine solution of the alcoholic extract of jaborandi, placed the drug in my hands, and requested me to observe its physiological action. I have been able to make some observations, which are confessedly very incomplete; but I am induced to publish them, since they seem to have some interest, and because I shall be quite unable to resume them until after the close of the term, it being practically almost impossible for me to pursue any serious investigation while the class-teaching is going on.

1. *Effects on the General Nervous System.*—Injected beneath the skin of the frog, jaborandi causes tetanic convulsions not unlike those of strychnia. These continue when the brain has been removed, but do not appear after destruction of the spinal cord. The mechanism of their production is, therefore, not peripheral, but central and spinal. In two dogs which had previously been placed under the influence of morphia, and in two rabbits to which chloral had previously been given, no such convulsions were observed. The difference between the frog and the mammal may have been a question of dose. To settle this, further observations are necessary. I could find no marked effect on the irritability of the motor nerves or of the muscles; but on this point, also, I speak with reserve.

2. *Effects on the Circulation.*—In the dog (under morphia) and in the rabbit (under chloral), injection of jaborandi into the jugular vein was followed almost immediately by a distinct slowness of the pulse-rate. No initial quickening (Dr. Ringer observed quickening of the pulse in the human subject) was observed. This, again, may be a question of dose, and of rapidity of entrance into the circulation. The pulse was brought down to as much as one-third of its previous rate. The effect in the case of the rabbit came on very rapidly, soon reached a maximum, and then speedily diminished.

During the height of the effect, stimulation of the pneumogastric

nerve produced the ordinary inhibitory results, the heart being brought to a diastolic standstill, and resuming its beat afterwards on the cessation of the stimulus.

In the frog, the slowness of the heart's beat was carried to actual stoppage, the heart remaining motionless and distended in diastole. While the animal was in this condition, the injection of atropine brought back the rhythmic beat.

We may infer from this, that the action of jaborandi (like physostigmin) in rendering the heart's beat slow, is through stimulation of the inhibitory fibres of the pneumogastric. The jaborandi, however, apparently, while exciting, does not rapidly exhaust the inhibitory fibres.

An attempt was made to recall in a frog, by the injection of jaborandi, the inhibitory power of the pneumogastric nerve, which had been suspended by the action of atropine. This, however, failed.

In the dog and the rabbit, this slowness of the pulse-rate was accompanied by a fall of blood-pressure, distinct, but not of any very great extent, coming on rapidly; in the case of one rabbit, causing a descent of the pressure-tracing almost imitating the effects of stimulation of the pneumogastric.

If the web of the frog's foot be examined while jaborandi is injected beneath the skin of the back, the arteries are seen to dilate, and the capillaries and veins to become full and red. The rapidity of the flow of blood, in spite of the dilatation, diminishes very considerably, so much so, that eventually a nearly complete, or even quite complete, stasis is observed over the greater part or whole of the web. This may be seen not only when the heart is at a standstill, but also when it is beating as rapidly as twenty times a minute. When the heart is revived by atropine, the stasis gives way, but only partially, and a very slow imperfect circulation is set up again. This same stasis was observed both when the sciatic nerve was left intact, and when it had previously been divided. Speaking under all reserve, and in view of future observations, I am very much inclined to believe that the stasis cannot be wholly due to the action of the jaborandi on the heart and vaso-motor nerves, but that a direct influence, of some kind or other, is exerted.

Injected into the jugular vein of a rabbit in which the sympathetic nerve of one side had been divided, jaborandi caused first of all a contraction of the vessels of the ear on the side where the nerve had been divided. This contraction was followed by a dilatation. A second injection caused a second contraction, succeeded again by dilatation. Under the full influence of jaborandi, stimulation of the divided sympathetic caused contraction of the vessels and pallor as usual.

After the injection of jaborandi, the vessels of the ear on the side on which the sympathetic was intact were dilated, but apparently not to the same extent as on the other side.

Paralysis of the normal vaso-motor influence does not, then, seem to be one of the most prominent characteristics of jaborandi.

The tracing of the blood-pressure was remarkable for the great flattening of the respiratory curves, a flattening which could not be explained by changes in the respiratory movements. This change in the respiratory curves, added to the bold pulse-curves of the slowly-beating heart, gave very distinct features to the tracing.

3. *Effects on Secreting Organs.*—In the dog and rabbit, very soon after the injection of jaborandi, a thick viscid mixture of mucus and saliva dropped from the mouth. A clear fluid ran from the eyes and nose. When a cannula was placed in the submaxillary duct, a flow of saliva, having the characters of chorda-saliva, took place very soon after the injection of jaborandi. The secretion speedily reached a maximum, and then declined. This excitation of the gland was but little, if at all, affected by previous division of the chorda tympani, and it was, therefore, peripheral in its mechanism. After the injection of jaborandi, electric stimulation of the chorda tympani caused an increased secretion, but quite out of proportion to the flow caused by a similar stimulation before injection. In fact, the jaborandi appeared rapidly to exhaust the gland.

In the frog, jaborandi caused a viscid secretion from the mouth and from the whole surface of the skin. Division of the sciatic produced no marked effect on the secretion from the skin of the leg; but this point also requires closer examination.

In the dog, there was found, after death, a large quantity of mucus in the trachea and bronchi, and a considerable amount of acid fluid in the stomach.

Jaborandi apparently increases the peristaltic action of the intestines, and in some way affects the urinary apparatus; but on these points, as also on its influence over the eye, the liver, and the secreting powers of the kidney, I have as yet been unable to make any precise observations.

In conclusion, I would point out that jaborandi in many points is similar in its action to physostigmin, but yet has distinct characters of

its own; that its action on the heart may be regarded as indicative of the care with which it should be employed therapeutically for the sake of its other qualities; and that its effect on secreting tissues—for example, the skin—and its peculiar action on the general circulation, present physiological problems of very great interest. To these I hope to be able before long to return. Of course, an isolation of the active principle, or of the active principles—for there may be more than one—is much to be desired.

EXCISION OF THE UPPER HALF OF THE FIBULA WITH A CARTILAGINOUS TUMOUR.

By THOMAS ANNANDALE, F.R.S.E.,

Surgeon to the Edinburgh Royal Infirmary, and Lecturer on Clinical Surgery.

A. D., AGED 30, was admitted under my care on March 17th, 1873. Four years before, the patient had a cartilaginous tumour removed from the upper part of the fibula; but none of the bone was taken away, the growth being simply torn from its attachment to it. The part remained well for about two years; but after this the growth returned, and continued gradually to increase in size.

An examination determined the existence of a tumour as large as an infant's head, firmly attached to, and evidently growing from, the upper half of the fibula. It was firm to the touch, somewhat lobulated, and projected principally inwards towards the popliteal space and calf of the leg. There was a cicatrix near the head of the fibula, the result, we were told, of the old operation. At first sight, amputation of the limb appeared to be the only method of successfully removing the tumour; but, after taking into consideration the nature of the growth and the site (the fibula) of its origin, I thought it might be possible to take it away thoroughly by excising the portion of bone from which it grew. The operation would necessitate the taking away of the entire upper half of the fibula; and two risks required to be avoided: (1) injury to the knee-joint in disarticulating the head of the bone; (2) injury to the popliteal vessels and nerves.

With these points in view, I undertook the operation on March

21st. The superficial aspect of the tumour was first exposed by a longitudinal incision about six inches long, made on the outer edge of the fibula, and by a shorter transverse one passing inwards across the calf at right angles to the centre of the first. Portions of several of the muscles were adherent to the growth, and required to be dissected off or cut across. The posterior tibial artery ran along a groove in the

lower part of the growth: and, as it could not be separated, it was ligatured and divided. The posterior tibial nerve was dissected away from the tumour, and left uninjured. The fibula was now sawn through about its centre; and its upper half, together with the growth, being laid hold of, it was drawn outwards, so as to allow some of the deeper portions of the tumour to be easily separated, and disarticulation of the head of the bone accomplished, with the least risk of injury to the knee-joint. By this means, the entire growth was surely removed; and, the edges of the wound being brought together, antiseptic dressing was applied. The tumour, when examined, was found to be growing from a little more than the upper third of the fibula. It was a good example of the cartilaginous growth; and, when the adherent textures had been dissected from it and the portion of the fibula to which it was connected, it presented the appearance figured in the illustration. From the close connection of the tumour to the fibula, it was very evident that no operation short of the removal of this bone could have been successful in taking away the whole disease.

On the 23rd, it was reported that the patient's progress was most satisfactory. On April 2nd, the report was, that the wound was rapidly contracting, and the general health excellent. On April 27th, the patient rose for the first time, using crutches. On May 8th, he was able to walk round the ward without support. The wound was very nearly healed, and was quite superficial. On May 12th, the patient left the hospital with a most useful limb. He could move the knee-joint freely, and bear good weight upon the legs.

REMARKS.—The satisfactory result of this case is an addition to the successes of conservative surgery. The non-malignant nature of the tumour, the history of its exact place of origin, and the secondary part which the fibula takes in connection with the support of the leg, were the circumstances which encouraged me to operate in the present case. The dissection of the fibula at an early stage of the operation was found to be a great assistance; for it permitted the tumour to be drawn away from deep and important structures, and thus diminished much the risk of injury to them during the deeper dissections.

CLINICAL MEMORANDA.

CASE OF POISONING BY HOMŒOPATHIC SOLUTION OF CAMPHOR.

THE case of camphor-poisoning related by Dr. George Johnson in the JOURNAL of the 6th instant, has induced me to look up my notes of a case that came under my observation about fourteen months ago.

Last winter, a young lady about twenty years of age, who generally enjoyed good health, while dressing about half-past seven to go out to an evening party, became very giddy and unwell. She went into the next room to her sister; said she felt very ill; threw her arms around her, and was immediately seized with strong convulsions. I was sent for; but, not being at home, she was seen by Mr. Armstrong. The convulsions had passed off. In about a quarter of an hour, there was free vomiting, and the patient remained unconscious for some time longer. I was requested by a second messenger to see her as soon as I came home. I did so a little before eleven. She complained at that time much of headache and giddiness, and was evidently confused. Her pulse was quick; skin moist. Her father told me down stairs that she had had an epileptic fit. I expressed my unwillingness to believe it was a case of epilepsy, until I failed to discover that it originated from some other cause. At the request of her parents, I visited her again in two hours—about half-past 1 A.M. Having had some sleep, she seemed more comfortable, and was decidedly clearer mentally. After much conversation and inquiry, which did not elicit anything of importance bearing on the illness, when I had almost despaired of gaining any further information, her mother told me that the only thing her daughter had taken that evening after dinner was a few drops of camphor while she was dressing, for a slight cold in the head; and "that of course", she added, "could not make her ill". I thereupon expressed a wish to see what remained. A half-ounce bottle was produced, more than half-full, labelled "homœopathic solution of camphor", with the name of a respectable firm. There was no intimation of the dangerous potency of the drug. It was bought, I was informed, because it was considered good for a cold; and many ladies took it for that reason. The lady said, moreover, that as it was a *homœopathic* preparation, she never doubted its being a safe one. I dropped fifteen drops (which was admitted by the patient to be about the quantity taken) into a tumbler with a wine-glassful of water, when a large deposit of camphor took place. The previous perusal of Dr. George

Johanson's and Dr. Clifford Allbutt's striking and instructive cases of poisoning by this strong solution enabled me at once to assure the friends of the patient that it was a case of camphor-poisoning, and that there would be no recurrence of the attack if the dangerous medicine were at once discarded from domestic use.

It is worthy of remark, that, while chemists carefully label laudanum in small quantities "poison", they do not hesitate not only to sell a drug considerably more deadly in its character to anybody who asks for it without any intimation whatever as to dangerous properties, but rather mislead the public by using an adjective which, in former years at least, was associated with everything innocuous and absurd.

A. LEGAT, M.D., South Shields.

POISONING BY HOMŒOPATHIC TINCTURE OF CAMPHOR.

READING, in the BRITISH MEDICAL JOURNAL of February 6th, Dr. George Johnson's statement of cases showing the poisonous effects of the homœopathic solution of camphor, I was immediately reminded of one which occurred on the evening of Christmas-day. I was sent for to see a young man who had suddenly fallen down insensible. On reaching the house, he had recovered, and was seated on a chair, looking pale, and with a weak pulse. A small half-ounce bottle was shown me, labelled "mother tincture of camphor". He said he had been accustomed to apply two drops at a time into a decayed tooth for tooth-ache; but, not finding relief, had repeated and increased the quantity several times on the present occasion, when suddenly, surrounded by a party of friends, he fell down insensible. Not being then aware of the strength of these homœopathic solutions, I attributed the effects to sudden fear lest he should have overdone the thing. After lying for some minutes unconscious, his friends told me he gradually came round. He had emptied the contents of the bottle. How much it contained, I cannot say. The young man was in good health, had walked two miles to visit his friends, and was going to walk back.

FREDERICK C. G. ELLERTON, Lindley, near Huddersfield.

CHILL OR MALARIA.

THERE appears to be considerable difference of opinion just now as to the cause of ague, whether it is due to malaria or produced by a chill. I live between two tidal rivers, the Cuckmere and the Ouse (Sussex). The inhabitants of the villages on the eastern banks of these rivers are very subject to ague, especially in the spring; so much so, that two clergymen and several tenants of the farms are unable to live in their parishes. I was some time since on a visit to the Rector of Waldron, a parish fifteen miles from here, situated on high table land with a dry sandy soil. My friend informed me that he had never seen a case of indigenous ague, but that several of his parishioners go down into the valleys of those tidal rivers in August during the harvest month, return home perfectly well, but in the following spring many of them are attacked with ague. On the contrary, those who migrate to the hop-gardens of Kent to assist in hop-picking, although they go a month later, and are, in consequence, exposed to more cold and wet than the harvesters, escape scot free. These are, I think, conclusive proofs of the agency of malaria in the manufacture of intermittent diseases, and that the "chill theory" is fallacious.

CURIOUS CASE OF OVERLOOKED STRICTURE OF ŒSOPHAGUS, AND POSTPHARYNGEAL ABSCESS.

A WIDOW, advanced in years, poor, but far from destitute, was transferred to my care in July 1873, as an old standing case of debility, with a character for grumbling. The treatment adopted had been various, the most efficacious as tested by her complainings—allowance of extras from the parish. In 1872, I find her ordered mutton and cod-liver oil, and returned as having debility; and had I earlier books, we should find similar entries for ten years or more. When I visited her, she was sixty-three years of age; lean, sallow, with a somewhat full throat, and a tongue and pulse not calling for notice. She was full of complaints: amongst them, of her throat (pointing to the enlarged thyroid gland). I gave her "extras", and returned her "debility"; and sent her a *placebo* mixture. Matters ran on without any suspicion of her disease until about July 1874, when she began to complain of difficulty in swallowing. I directed her to drink some water in my presence, and she drank it far better than she would have led me to suppose she could; but yet, as it seemed to me, with an effort—

and so the fact of disease became established. But, whether the fault lay in some defect of nerve-supply, or in some growth or change within or outside the gullet, I could not, especially in the absence of an instrument with which to explore the oesophagus, decide. My opinion, however, inclined towards the first view—that the fault lay in the nerve-supply; and, moreover, from the way in which she drank the water, that she made the most of it. But the chronicity of her case, the character given her by my two predecessors, and my own experience of her, led me to take little or no interest in trying it further, and nothing new occurred until November 5th, when I was sent for urgently. I found her in bed. She told me she had been taken suddenly worse, and that now she was unable to swallow even a teaspoonful, and showed me that it was so. I tried to pass a small instrument down the gullet, but was unable even fairly to enter it. She lived by means of nutrient enemata until the 6th. At the *post mortem* examination, I found a large foul abscess behind the pharynx; and projecting from it, whilst intimately associated with the walls of the oesophagus on all sides, for a length of about two inches from the cricoid cartilage, a growth with all the apparent characteristics of a wart. I could not make out any passage through it, but there appeared to be a tortuous passage, not larger than a goose-quill, for more than half its length. The case is one which carries its own comments.

S. WILSON HOPE, L.R.C.P., Petworth, Sussex.

THERAPEUTIC MEMORANDA.

THE USE OF COTTON-WOOL.

IN the JOURNAL of January 9th, is a letter headed "Fungus of the External Ear," in which a correspondent, "D. McL," states, as the result of his personal experience, that cotton-wool produces irritation when introduced into the external auditory meatus. "D. McL." is not alone in this opinion, for Professor Gruber of Vienna also holds that cotton-wool is deleterious when used in cases where there is any discharge from the meatus. I have not his book on *Aural Surgery* at hand; but, to the best of my recollection, his theory is that irritation or even abscesses may be caused by retention of the fibres of the cotton-wool in the ear. On this account, at his *clinique* he always uses charpie instead. I am not aware whether he has tried unleached lambs'-wool, which "D. McL." recommends, but remember Professor Gruber mentioning an American kind of wool, with long fibres, I think, which he once met with and found as advantageous as charpie. Apart from its essentially different structure, may not the grease contained in the unleached lambs'-wool be, at least in part, the cause of its superiority to cotton-wool if this superiority be confirmed by experience? It would be of interest to hear the experience of any of the readers of the JOURNAL on the relative merits of cotton wool, unleached lambs'-wool, and charpie for insertion into the auditory meatus when there is any discharge from that canal. I may add that Professor Politzer, another eminent Viennese aurist, uses cotton-wool at his *clinique*.

E. CRESSWELL BAKER, M.B. Lond., Thurlow Square.

STRICTURE OF THE URETHRA AND ITS TREATMENT BY THE LAMINARIA BOUGIE.

It is generally acknowledged that the great objection to the use of the Laminaria bougie as a dilator in cases of urethral stricture, is its tendency to expansion beyond the seat of obstruction, and consequent difficulty of withdrawal. Having, as others have done, used the laminaria bougie in several cases, I have feared, on the above grounds, to continue its use. To avoid the expansion of the laminaria, I have, during the last two years, treated it in various ways, by varnishing, etc., but without any satisfactory result. Within the last few months, my friend Mr. A. Cooper Key has devised a method by which this tendency to expansion can be entirely obviated. It is as follows. A small portion of the laminaria is first filed away, and then lapped with the finest black silk, which is so applied, as not only to present a perfectly smooth surface, but to prevent all risk of slipping off. This coating of silk is next varnished, and when dry the instrument is ready for use. The important point in applying it, is to take care that the coated portion of the instrument be passed through the stricture, so that it shall correspond to that portion of the urethra immediately behind it. I am fully aware that strictures may be gradually dilated by passing the laminaria bougie, step by step, through them; but I am inclined to believe that the former method of treatment is to be preferred. Having some cases under treatment, I trust soon to publish the results.—SAMUEL LEE, Savile Row.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

BETHLEHEM ROYAL HOSPITAL.

REFUSAL TO TAKE FOOD, ASSOCIATED WITH SCIRRHUS PYLORI IN AN INSANE PATIENT.

(Under the care of Dr. SAVAGE.)

MARY E., aged 32, single, a governess, had suffered from delusions, and been untidy and dirty for three months before admission to Bethlehem. There was no history of insanity in her family. She had been well educated, and was of sober habits. She for a time talked incoherently; had a delusion that she had been married six times, and had had many children. She talked of cutting her throat, but never attempted to do it. For some three weeks before admission, she had been sleepy, and utterly regardless of what went on around her. She had had some vomiting, but made no complaint of pain.

On admission, she was in a most emaciated state; she had taken hardly any food for over a week. There was a peculiarly fetid smell about her, that necessitated the "night watch" sitting outside the bedroom. Milk, beef-tea, and stimulants, were given by spoonful every half hour, the patient being too weak to resist; for about forty-eight hours she retained the food taken, and was got up for an hour or two daily; but, as she gained strength she refused food, and what she was forced to take she vomited. The terrible fetor passed off after a day or two. No tumour could be detected, though malignant disease was suspected. The patient lingered for eleven days, and then died.

Post mortem, a scirrhous ring around the pylorus was found; but the chief mass of disease was in the ileum and mesenteric glands, which were hard. In the ileum were several thick-walled ulcers of breaking down cancer.

Dr. Savage remarks that "we read of cancerous insanity when the brain is implicated in malignant disease. He objects to the term, as much as he would to such cases of the above being called specially cancerous insanity."

Dr. Savage also writes, "It seems to me to be too general to look for the symptoms of insanity in the brain alone, and also to look for all the causes—or the chief, at least—in the same organ. It is true, that we have cases of insanity in which the brain alone is found diseased; but we also have general states of degeneracy in which insanity appears as one symptom only of decay. To this last class belong some cases of senile insanity, and also some of general paralysis. Of still greater interest are those cases in which the mental symptoms are reflected from some other organ; thus, we have seen several cases in which the refusal of food has been due to some organic abdominal disease; of this class, the above case was a complete example. Many of our patients refuse food in consequence of inexplicable feelings in their digestive tracts; these sensations being uniform and constant, overrule all reason. It is not only in cases in which we find crass disease—as in our present example—that such feeling and such refusal of food occur, for we have had cases during the past year in which refusal of food was associated with the early dyspepsia of phthisis. These cases, which we have called 'reflected,' differ from others that have one or more important organs affected, but in which the insanity depends rather on the cachexia than on the mental result of derived impressions. We shall hope to consider in future papers some other cases of insanity associated with cachexia."

GLASGOW WESTERN INFIRMARY.

TWO CASES OF DROPSY: QUESTION OF RENAL ORIGIN: DIFFICULTIES OF DIAGNOSIS.

(Under the care of Dr. GAIRDNER: reported by Dr. FINLAYSON.)

THE two women whose cases are now reported were in the ward at the same time, and formed an instructive clinical study, as affording a contrast to each other, and also to other cases of dropsy of well marked renal origin. Although the exact lesions were not accurately determined, even on dismissal, the cases yielded so far to prolonged investigation, as to afford some valuable lessons to the clinical class.

CASE I. *Edema of Lower Limbs and Vomiting; Complexion Pallid; Urine Pale, of low Specific Gravity, but Non-Albuminous; Excessive Secretion of Urine, diminished at times, and once nearly suppressed under Severe Vomiting, attended with Cramp-like Spasms; Detection of Sar-*

cine Ventriculi, and Signs of Dilated Stomach: Discussion of Diagnosis.

—Jessie M., admitted November 14th, 1874, was a domestic servant thirty-one years of age. She came in with a vague report of diseased kidneys; and, at a first look, many things certainly seemed to confirm this idea. She had, on admission, considerable oedema of the feet and legs, and some distension in the region of the stomach; her complexion was extremely pallid, she suffered from thirst, and she was very much troubled with vomiting. This occurred usually every day, once or oftener. No clear evidence could at first be obtained of ulceration or other serious affection of the stomach; the urine was alkaline, pale, of low specific gravity, and, although found to be free from albumen on admission, there still remained some suspicion of renal disease. The absence of albumen was confirmed by several subsequent testings, but Dr. Gairdner still thought the kidney might be at fault, and requested the urine to be measured. On November 30th, it was found, to our surprise, to amount to 109 ounces in the twenty-four hours; and, on the day following, to 125 ounces. The specific gravity was about 1011, and the colour pale. This large quantity of urine raised fresh doubts as to the soundness of the kidneys, and I directed the sister of the ward to collect various specimens at different hours of the day, to see if albumen appeared at any period of the twenty-four hours. This was done on several occasions, and revealed great differences in the colour and specific gravity of certain samples: some of them, especially after food, were high-coloured, turbid, and of good specific gravity (1020 or thereby); but the urine passed in the morning was always very pale, and of a specific gravity as low sometimes as 1007. No albumen, however, could be detected by the tests employed, viz., heat, and nitric acid in the cold; phosphates were usually precipitated on boiling, and occasionally urates were thrown down on the addition of nitric acid; and, in some of the specimens, the original turbidity of the urine prevented the reactions from being perfectly conclusive. Prolonged and repeated microscopic examination of the urinary sediment failed to detect tube-casts, or other renal derivatives. The quantity of urine varied somewhat. On December 12th, it was distinctly less abundant, only about 70 ounces in the twenty-four hours; and, at this same time it was noted, that the patient had not been so well, and that vomiting had occurred during the night. The vomited matter was preserved on December 16th, and found to consist of an abundant brownish-black pulaceous mass, highly acid, and containing numerous sarcine. This was the first of such vomiting since admission. On any previous occasion it was simply food which came up; she had, however, vomited black matter like this before, but no black motions from the bowels had been noticed; the bowels throughout were very costive. On this day, the quantity of urine noted was 32 ounces, on the day before 47 ounces, and on the day after 39 ounces. The specific gravity of these diminished quantities (i.e., the specific gravity of the whole quantity for twenty-four hours) was considerably higher than those of the larger quantities before (1017 as compared with 1011). These facts are insisted on, for the view of the case now taken was, that the mischief was essentially and originally gastric; on January 5th, some corroboration of this was afforded by finding the stomach evidently dilated, and traceable by succussion over a very undue area. The present illness was said to be of three months' duration, but a similar illness had occurred three years ago, six months after the birth of a dead child. The slight improvement in the gastric symptoms which had continued, with intermissions, till Christmas, had now ceased, and, on January 7th, in the absence of the resident physician, one of the other assistants was summoned in the afternoon to see this patient, and found her somewhat cold and suffering from cramps, especially in the arms and legs; the fingers being bent in, but so far as could be judged, without any loss of consciousness. Under treatment by warmth to the extremities, etc., she quickly recovered, and seemed as well as usual at night. During this attack, she vomited much, and the patient attributed her relief chiefly to the vomiting. This attack of spasm or cramp came on in connection with a great diminution in the urinary secretion, to such an extent, that only four ounces had been passed in twenty-four hours of the day in question; but the quantity gradually came up again to the normal standard. This naturally suggested to the gentleman thus called (who was, of course, unacquainted with the case), the idea of uræmic poisoning, and perhaps, even, in full view of the facts, this cannot be absolutely excluded; the probability seems, however, rather to be that the cramps were directly connected with the gastric disorder, and that the diminution in the urine was due to the copious vomiting, seeing that this had been found to produce, or, at least, to be associated with, such a diminution on the former occasions referred to, although to a less extent. The alkalinity of the urine, and the acidity of the vomited matters, have long been known to be frequently associated. The oedema which was chiefly, if not exclusively, in the legs and feet, disappeared when the

patient kept in bed, and was no doubt due to the anæmia resulting from impaired digestion. The copious urine was probably connected with the free quenching of the thirst of which she complained; this thirst, likewise, was probably a gastric symptom, but no details exist as to the amount of fluid she actually swallowed. The whole features of the case seemed thus ultimately to point to gastric disorder, although many of the facts appeared at the time extremely perplexing.

CASE II. *History of General Anasarca a few Months after Delivery; on Admission, Moderate Ascites with Oedema of the Abdominal and Thoracic Parietes, and Slight but Temporary Albuminuria with Tube-casts: Persistence of Dropsy without Albuminuria, or other discoverable cause; Subsequent Discovery of Enlargement and Induration of the Liver: Remarks on Diagnosis.*—The second patient, Mrs. B., aged 27, admitted December 17th, 1874, complained chiefly of abdominal dropsy; she had, clearly, some effusion into the peritoneum, and considerable oedema of the abdominal and thoracic parietes. Her urine was found on two separate occasions, immediately after admission, to be distinctly, although slightly, albuminous. The history of the case bore plainly that, after a confinement a year ago, her health had been impaired, and that, about May last, general dropsy, involving the feet, face, arms, and trunk, had appeared, and that this settled down latterly into the abdomen and chest-walls. On admission, no oedema could be demonstrated elsewhere: her skin was extremely dry. The renal character of the case thus indicated, seemed to be confirmed by the detection of a few tube-casts; these were mostly hyaline, but some contained renal epithelial cells, and some of these were fatty; a few compound granular corpuscles were also seen; in addition to these, and to some pavement and scaly epithelium, there were considerable numbers of white cells (apparently pus), and a great quantity of branching vegetable growths. Dr. Gairdner, while admitting that the few tube-casts indicated probably a renal origin for the albumen, thought that it might possibly be due wholly, or in part, to pus from the vagina, although no leucorrhœa was known of, and he suggested an examination of a sample drawn off by the catheter.

Thus far the case seemed essentially renal: albuminuria, tube-casts, peritoneal dropsy, and oedema of the parietes, along with a clear history of general anasarca previously, all pointed in this direction. No cardiac lesion was suggested in any way, and none could be made out. The size of the liver could not be determined by percussion, owing to the distension of the abdomen; but there had been no jaundice since she was a girl, and her habits were evidently extremely regular and temperate. She did not suffer from vomiting, and she had never passed blood at stool. The only obscure point was the unusually localised character of the dropsy if it were really renal.

Curiously enough, the very day (December 22nd) on which the sample was drawn off by the catheter, the urine had undergone a great change; the quantity had increased (not apparently from medicine), and the colour was paler; the specific gravity was 1012, but no trace of albumen could be made out on careful testing with nitric acid, and no tube-casts, pus, epithelium, or vegetable growths were found on microscopic examination; but the urine passed in the usual way that same day likewise failed to yield indications of albumen, so that this difference was not due to the use of the catheter. From this time, although frequently tested, albumen could not be detected in the urine; not unfrequently a precipitate of urates occurred on adding nitric acid, and, as a rule, a very marked colour (pink or purple) formed at the junction of the layer of nitric acid and the urine. The dropsy persisted, varying slightly in disposition in the parietes, being apparently influenced by position; and, if the patient were up much during the day, her feet became swollen, but only to a slight extent. The continued absence of albumen from the urine, and the disappearance of tube-casts from the sediment, although very sedulously searched for, seemed to throw doubt on the renal origin of the dropsy. Her own medical attendant had, moreover, in the early period of the illness, told her, she said, that she had some enlargement of the liver; and, about the same time, he had tested the urine, and she understood, found it right. Her complexion, which was pallid, had also a dingy tinge suggestive of hepatic disorder, and the persistence of the local dropsy, out of proportion to any oedema elsewhere, raised suspicion of the liver.

On examining, in view of these facts, Professor Fritsch's cases of atrophy of the liver, in his well-known book, and Dr. Austin Flint's valuable article on Hydro-Peritoneum, in the *American Journal of Medical Sciences*, April 1863, it appeared to me that not a few real hepatic cases had presented in the early stages, more or less general anasarca and oedema, before the peritoneal dropsy supervened, and Dr. Gairdner, in his examination of this patient on January 13th, directed particular attention to the state of the liver. The abdomen was, perhaps, not so tense as on admission—at least, it measured an

inch less ($32\frac{1}{2}$ instead of $33\frac{1}{2}$ inches), and this, perhaps, favoured the examination of the parts; for he had now no difficulty in satisfying himself, by palpation, of a considerable projection of the liver downwards towards the umbilicus, and towards the left hypochondrium, the organ being felt partly in contact with the walls, and partly by impact through the fluid—at least, as low as about an inch above the umbilicus; and, in the left hypochondrium, at least two or three inches from the mesial line. The hand, likewise, was sensible of undue firmness and resistance in the organ, but no information could be obtained as to the character of the surface; the enlargement seemed also traceable by the hand, although less distinctly, into the right flank when the patient lay on this side; no definite statement could be made as to the spleen. These facts were sufficiently obvious to be verified by many of the class, after they were directed how to make the examination, by dipping the flat hand suddenly down upon the organ.

This examination seemed to stamp the case as essentially hepatic, and to give the renal element in it a secondary and transient place. The urine still continued free from albumen when tested by heat and nitric acid; and the ferrocyanide of potassium test, the carbolic acid test, and the picric acid test likewise failed. The testing of various samples at different hours of the day was carried out on January 21st. Out of seven samples passed at various hours, from early morning till late at night, a very faint trace of albumen was found only in two, by means of nitric acid after contact prolonged for several minutes, viz., a trace in that passed at 2.50 P.M. (about two hours after dinner), and a still fainter trace in the sample passed at 6 P.M. (an hour after tea), the intervening specimen at 4 P.M. being free. The specific gravity of these samples varied only slightly, 1017-1022. Portions of the sediments from the afternoon samples were removed (together) for subsequent microscopic examination: pus corpuscles, and epithelium from the vagina and bladder were found as before, and, after prolonged examination, I detected one or two hyaline tube-casts. The urine throughout the whole case was perhaps somewhat under the average quantity, 30 ounces, representing a rough estimate of the notes on the whole; the specific gravity was also rather under the average of normal urine, and the colour rather pale. The temperature throughout showed a complete absence of fever.

The case seemed at last intelligible on the supposition of some form of liver disease, attended with enlargement of the organ, giving rise to signs of local dropsy, and involving secondarily and temporarily the renal secretion, perhaps in part from pressure, perhaps from imperfect assimilation of the food.

SELECTIONS FROM JOURNALS.

THERAPEUTICS.

SUBCUTANEOUS INJECTIONS OF MORPHIA.—Dr. Alling, after making numerous experiments on himself, reports in the *Alger Medico-chir.*, No. 10, 1874, that local pain is equally soothed by subcutaneous injection of morphia at whatever point of the body it may be performed. For minor reasons, such as facility of making the puncture, etc., he chooses the internal part of the arm. He looks upon the use of the aqua laurocerasi as an excipient as particularly painful.

PETROLEUM-OIL AS A VERMIFUGE.—Basing his practice on the fact that horticulturists and veterinary surgeons use petroleum-oil as a parasiticide, M. Perrin has tried injections of this substance as a remedy for oxyurias. He gives it in doses of half a teaspoonful made into an emulsion, with 125 grammes of water, and the injection should be repeated many days in succession. M. Perrin proposes to treat lumbrici and tania by capsules, containing 25 centigrammes (nearly 4 grains) of petroleum, of which ten or twelve should be taken in the course of the twenty-four hours. This substance, when taken in small doses, cannot bring on any unpleasant consequences, as two or three small glasses of it may be taken with impunity. *Gazette des Hépitaux*, August 11th, 1874.

TREATMENT OF RHEUMATISM BY PROPYLAMINE.—*Zeitschrift für die Deutsche Medicin*, No. 74 (1874) has found propylamine very efficacious in acute articular rheumatism. Its action is manifested in a rapid fall of the temperature and pulse (even to as low as forty-eight beats), and a rapid decrease of the pain and swelling. A few hours after its administration, profuse sweats set in. The average duration of the disease in his cases was from four to eight days. He does not regard the simultaneous occurrence of heart-disease as a contraindication to the use of propylamine. *Allgemeine Medicin. Central-Zeitung*, February 6th.

TREATMENT OF PSORIASIS.—Dr. Zimmerhaus employs, for the treatment of this affection, carbolic acid in the form of pills. Each pill contains three-fourths of a grain of carbolic acid. He begins by prescribing six daily, and increases successively to twenty pills in twenty-four hours. Cutaneous appearances generally disappear after four or at most seven weeks, of this treatment. *Wiener Medizinische Presse*, No. 42, 1874.

ON THE USE OF CYANIDES IN ACUTE ARTICULAR RHEUMATISM.—M. Luton of Rheims, in the *Bulletin Général de Thérapeutique*, highly recommends the use of the cyanides in the treatment of acute articular rheumatism. The two cyanides with which he has experimented are those of zinc and of potassium. The first is a white inodorous tasteless powder, insoluble in water, but probably soluble by the gastric juice. M. Luton administers it in average doses of $1\frac{1}{2}$ grains daily, either in pills or held in suspension in some preparation of gum. The cyanide of potassium is more active; is administered in maximum doses of from $1\frac{1}{2}$ to 2½ grains, and preferably in pills on account of its disagreeable flavour. The pills should be silvered and kept in a stoppered bottle. The cyanide may be taken during or after meals, if there be any advantages in so doing. M. Luton reports many cases in support of the proposed medication. He affirms that, as a total result, it is certain that cyanides cure acute articular rheumatism in its fundamental form and its diverse transformations. They cure it by shortening the duration of the disease in a marked manner, and by diminishing the risks of the complications which are characteristic of this affection.

SUBCUTANEOUS INJECTION OF STRYCHNIA IN AMAUROSIS AND AMBLYOPIA.—Dr. Hasket Derby extols (*Boston Medical and Surgical Journal*, November 5th) the efficacy of subcutaneous injection of strychnia in certain cases of amaurosis and amblyopia. He has found it particularly useful in cases of "amblyopia ex abusu", arising from the long-continued, excessive use of alcohol or tobacco. In this affection, the acuteness of vision slowly and regularly diminishes. There is no contraction of the visual field, no break in its continuity, but distant and near objects grow indistinct, as if enveloped in a thickening mist. Glasses are of no avail for distant objects, though convex lenses for a time sustain the failing powers of the eye for the near. Reading and writing finally become impossible. If the disease progress, blindness may ensue. There is no change in the external appearance of the eye. The ophthalmoscope alone reveals a change; at first, congestion, and, towards the end, atrophic degeneration, of the optic nerve. Dr. Derby has found that this amblyopia occurred 52 times among 6,602 patients, about .8 per cent. In hospital practice, he is satisfied that it occurs more frequently. Of his 52 cases, 16 proceeded from the use of tobacco alone, 5 from that of alcohol, 31 from both combined.

COMBINED ADMINISTRATION OF CHLORAL, MORPHIA, AND ATROPIA.—Dr. Roberts Bartholow of Cincinnati read (October 19th) before the New York Society of Neurology and Electrology, a paper on this subject. He finds that chloral differs from morphia, when injected subcutaneously, in the more decided systemic effects and the less local impression on the sentient nerves. As regards the systemic effects, the action of chloral is very much the same when administered hypodermically as by the stomach. The chief danger is an arrest of the respiratory movements. Chloral does not exert any chemical action on atropia when the two are held in solution together, for dilatation of the pupil of a cat takes place when the combined solution is instilled into the eye. Dilatation of the pupil also happens when they are administered hypodermically together. An apparent antagonism is observed as regards their action on the heart when the solutions of chloral and atropia are placed in contact with the heart of a frog when in position in the chest, after division of the medulla, or when the heart is removed. The action of the heart is found to continue much longer when a lethal dose of chloral is administered together with atropia. In rabbits, the same result is produced by the conjoined administration of the two agents. Atropia prolongs the chloral narcosis several hours in rabbits, and diminishes the sensibility to pain. In man, the excitant action of atropia hinders the occurrence of the chloral narcosis, but rather deepens the sopor when it at last supervenes. The effects of atropia last much longer, and are, apparently, in no way prevented by chloral. Morphia deepens in every way the effects of chloral. Dr. Bartholow found, in some experiments on himself, that many of the unpleasant effects of morphia are modified as regards the wakefulness but are not modified as regards the subsequent nausea, vomiting, vertigo, and constipation. When the two agents are administered conjointly, a much less quantity of chloral is necessary in order to produce

sleep. These agents act much more happily when administered simultaneously. Chloral causes sleep, morphia relieves pain, and atropia prevents or lessens the depression in the respiratory and cardiac movements caused by the other two, whilst it contributes to their cerebral effects. The combination of chloral, morphia, and atropia, is adapted to cases of insomnia caused by pain, or in which chloral and morphia alone merely increase the cerebral excitement, as in hypochondria, puerperal mania, etc. This combination is also indicated in cases of fatty and irritable heart. When pain is to be relieved, chloral is not so serviceable alone as in combination with morphia and atropia. The local administration—the insertion of the medicament at the site of pain—is more effective than the merely systemic impression: especially in tic douloureux, sciatica, and coccydynia. The combination of a local irritant and benumber with a systemic anodyne is more curative than either used singly. In cases of *muscular spasm*, the author of the paper had obtained excellent results from the combined use of chloral, morphia, and atropia, and he especially called attention to the efficacy of these agents in the cramps of cholera. Many cases of spasmodic asthma and hay-fever had been benefited by their conjoint administration.—*New York Medical Record*, December 1st, 1874.

MIDWIFERY AND DISEASES OF WOMEN.

ON THE INFLUENCE OF SYPHILIS ON PREGNANT WOMEN, UNDER VARIOUS MODES OF TREATMENT.—Dr. F. Weber of St. Petersburg has published in the *Allgemeine Medicinische Central-Zeitung* for February 3rd and 6th, the results of his observations in 129 pregnant women suffering from syphilis admitted into the Obukow hospital during the ten years 1863-73. Of these patients, 35 were treated only locally or not at all; 55 were submitted to treatment by inunction; in 23, inunction was combined with the internal use of iodine (iodide of potassium with tincture of iodine); 19 were treated by the internal use of a combination of iodide of potassium and corrosive sublimate; and in 17 cases iodide of potassium was the remedy used. He gives abundant statistical details, and sums up as follows. 1. In general, the course of pregnancy was interrupted in 25, or 20 per cent. of the cases; this proportion, however, may be reduced, when it is remembered that of the patients four had erysipelas of the head, one recurrent fever, and one exanthematous typhus. 2. Every method of treatment which interferes with the digestive system predisposes to untimely birth. 3. In the cases submitted to simple local treatment, there were 20 per cent. of premature births; in three, however (suffering from typhus and recurrent fevers, and from extensive formation of abscesses), violent fever appears to have been in part the cause of the untimely labour. 4. In pregnant women who were treated by inunction together with local remedies, there was no disturbance of the course of pregnancy. This confirms Professor Sigmund's conjecture, that the inunction treatment has no injurious influence on the course of pregnancy. 5. In women in whom inunction was either accompanied or followed by the internal use of iodine, the percentage of premature births was 37; this, however, may be reduced to 20 by deducting two severe cases of erysipelas of the head. 6. General treatment with a solution of iodide of potassium and perchloride of mercury was attended by 15 per cent. of premature births. 7. In cases treated by iodide of potassium, 42 per cent. of untimely births occurred. 8. The injurious action of general treatment did not in any way correspond to its duration, but much rather to its effects on the digestive organs. Hence general treatment should be interrupted on the first indication of indigestion in a pregnant woman. 9. The period of pregnancy at which general treatment is commenced appears to have no influence on the occurrence of premature labour. 10. The stage of development of the syphilis seems to be not without influence on the occurrence of untimely birth. 11. The puerperal period ran an abnormal course in 4 out of 14 cases treated locally, in 3 out of 8 treated by inunction and iodine, in 3 out of 4 treated by iodine and sublimate (one of these patients died), and in 4 out of 10 treated by iodide of potassium.

CONDITION OF THE UTERUS FIVE WEEKS AFTER DELIVERY.—Dr. Wm. F. Jenks has examined the uterus five weeks after delivery; and he has given (*American Supplement to the Obstetrical Journal*, November 1874) an account of his investigations. He has been led to coincide with the opinion now held by some of the best histologists, that the reproduction of the muscular tissue is effected through the proliferation and division of connective tissue cells, forming thereby indifferent or embryonic cells, which subsequently develop into the unstripped muscular fibre. He has been able to find no evidence of the division of the nucleus of the fatty degenerated muscular cell, while it is contrary to the laws of reproduction to suppose that a cell, itself under-

going death by molecular fatty degeneration, should produce a new cell endowed with vitality. The parenchyma of the uterus submitted to him for examination was infiltrated with small round young cells, to which the name of embryonic or indifferent cells has been given, because they are impressed with the type of the tissue in which they are generated, and are capable of development into muscular, nervous or osseous tissue. On examining the internal muscular layers of the organ, the remains of the old hypertrophied muscular fibre were evident; the individual cells, however, were much diminished in size and filled with fatty granules; but nowhere else in the uterus was there a trace to be found of the former muscular structure; hence the inference is rendered probable, that the process of rejuvenation proceeds from within outwards, and approaches completion at or near the fifth week after parturition. That opinion coincides nearly with that of Heschl, who states that the fatty degeneration and absorption of the old muscular structure is not completed before, nor does it continue after, the eighth week. Priestley, in his treatise on the *Gravid Uterus*, writes that the colossal muscular fibres are not found after the third week, the middle coat now consisting of embryonic cells. Dr. Jenks believes that, during the time when this active process of involution is taking place, rest in bed for ten days or two weeks, and subsequently a careful return to any active exercise, are plainly indicated. In dispensary practice, where the patients are drawn from the poorer class, unable or unwilling to submit to restraint after confinement, by far the commonest form of uterine disease is subinvolution of the uterus after delivery or abortion, with its attending ills of displacements and chronic catarrhal conditions of the mucous membrane. These depend for their existence on structural changes of the tissues, or rather on the arrest of certain changes which should take place, and which are not normally completed until the expiration of a month or more after delivery. In estimating the value of any mode of treatment of the puerperal woman, her condition six months or a year after her confinement must be the criterion, and not her general health a month after delivery. Even if this condition of subinvolution exist, the physical signs and symptoms are manifested only when the organ, engorged in consequence of a sluggish circulation—partly due to the implication of the muscular tissues of the blood-vessels in this arrested repair—sinks deeper into the cavity of the pelvis. The uterus usually becomes retroverted, inasmuch as it does not receive the proper support from the relaxed ligaments, vaginal walls, and perineal body; while the mucous membrane, owing to the passive congestion of the vascular system, passes into a state of chronic catarrh, and the accompanying disturbances, both local and sympathetic, slowly but surely develop themselves at a later period.

SURGERY.

A NEW METHOD OF OPERATING ON THE LARYNX.—In an article in the *Centralblatt für Chirurgie*, No. 20, 1874, Eysell says that, in order to displace upwards tumours of little mobility, lying in the lower part of the larynx, a needle (*prick-needle*) may be introduced in the middle line through the skin and membrane into the trachea, the tumour penetrated, and raised by depressing the handle of the needle. There is little or no hæmorrhage; and no reaction. In the same way, such tumours can be directly cut off by means of the needle used in tapping the tympanum; and adhesions of the vocal cords may be cut through. In an analogous manner, injections may be made with a Pravaz's syringe into laryngeal tumours.

MULTIPLE NEUROMA SUCCESSFULLY TREATED BY NERVECTOMY.—Kosinski relates in the *Centralblatt für Chirurgie*, No. 16, 1874, a case in which nodules lying in the corium were present on the posterior and outer surface of the right thigh as far as the lower third, and partly also on the buttock. They were round and oval in form, and varied in size from a pin's head to a hazel-nut; their number was about a hundred, and pressure on them produced radiating pains. In situation, they corresponded mostly to the inferior gluteal nerve; a few anterior ones, to the external cutaneous nerve. Internal remedies having been given without effect, the inferior gluteal nerve was divided as near to its central end as possible; the immediate result was the disappearance of sensibility in the affected part and in the swellings themselves. In some of them, especially those lying towards the anterior limit and the sciatic region, the tenderness was only diminished. While the wound was healing by suppuration, the tumours began to decrease; in four weeks, the larger ones were of only half their original size, and many of the smaller ones had altogether disappeared. Four months later, there was a still greater reduction in the size, with absence of pain, in the remaining portions.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, FEBRUARY 20TH, 1875.

THE ARTISANS' DWELLINGS BILL.

SEVERAL Bills for the improvement of the sanitary laws have already been laid before Parliament by Her Majesty's Government, one of which has reached our hands—viz., the Artisans' Dwellings Bill. The provisions contained in the Bill are in a Bill in to previous legislation on the subject, so that we must consider it as supplemental to the Act for improving the dwellings of the poor which was passed in 1868, and is known as Torrens's Act; as well as to all other Acts, private or public, which have been previously passed. The chief defects of Torrens's Act are, (1) its cumbrous mode of procedure; (2) the want of compulsory power by the local authority to build on the ground rendered vacant by pulling down the injurious dwellings; and (3) the absence of compensation to the owner for the houses which have been destroyed. We shall, therefore, consider by the light afforded by previous legislation, firstly, the objections to this Bill; and, secondly, the amendments necessary to make it workable.

The Bill consists of three parts, containing twenty-two clauses, and a schedule of thirty-three clauses. The first part contains the provisions respecting unhealthy areas; the second, those ancillary to the improvement-scheme; and the third, the general provisions for the serving of notices, penalties, saving clauses, and definitions. The schedule refers to the deposit of plans, the appointment of auditor, the proceedings on arbitration, the payment of purchase-money, power of entry, appeal, and costs of arbitration.

The first clause contains only the title of the Act. The second states that the Act shall apply only to the metropolis and to the urban sanitary districts in England containing at the last census a population of twenty-five thousand and upwards; and that the local authority shall be the Commissioners of Sewers for the City, the Metropolitan Board of Works for the rest of the metropolis, and the sanitary authority of the place for extra metropolitan districts. The first objection we have to make is to the limit here defined, because, and so if it be proposed to introduce another Bill, we do not see why urban sanitary districts containing less than twenty-five thousand persons, and rural sanitary districts, should be left out. The report and letters which have from time to time been published show that the conditions of our rural population are very often worse, if possible, than the dwellings of the poor in our urban districts.

Clause 3 states the reasons for which an official representation shall be made to the local authority that a district is unhealthy and requires improvement. This is a very important clause, and, unfortunately, does not carry out the statement made in the preamble, and limits very much the operation of the medical officer of health. In the preamble, it is stated that there are in certain portions of our cities and boroughs a great number of houses, crowded together, which, by reason of the want of light, air, ventilation, or of other conveniences, or from other causes, are unfit for human habitation, and should, therefore, be pulled down and re-erected. But, by clause 3, the only reason for which a medical officer of health can report an area to require reconstruction are the figures indicating a bad condition of health prevail therein; and that the prevalence thereof may be attributed to the density, narrowness, and bad arrangement of the streets and houses,

or to one or more of such causes. There is no power given here, except to a certain extent by implication, to condemn houses which are unfit for habitation for want of necessities of health recited in the preamble. We also have another strong objection to Clause 3; viz., that, if the local authority be not satisfied of the practicability of "applying a remedy, and of the sufficiency of their resources, and of the advantage to be derived by their district from the application of such remedy, and that an improvement-scheme ought to be made," they may put aside the report as so much waste paper. We need scarcely point out that any local authority desirous of evading the Act can readily do so in accordance with the terms of the Act itself, by assigning any one of the above mentioned reasons as an excuse for not taking action.

Clause 4 is one of great importance to a very large number of our profession, as by it metropolitan medical officers of health are required to make an official representation to their board or vestry, that an improvement scheme is required for certain parts of their district; and, in other places, the medical officer of health is to make a similar representation to the local authority which appointed him. Now, as medical officers of health are generally removable at the pleasure of the bodies appointing them, or are appointed every year, or for not more than three or five years, it is most unfair to make them take the initiative, without giving them any assistance in forming their opinion and dividing the responsibility. It is true, that medical officers have frequently shown great unselfishness and public spirit in carrying out the various sanitary acts; but it is almost too much to expect that they will expose themselves to attacks from the owners of small property sitting on their boards, for making the "representation" which is necessary to set the Act in operation. It is true that, if twenty or more ratepayers of the district complain to the medical officer of health of the unhealthiness of certain houses in his district, he is bound to report thereon; yet, practically, we know that this portion of the Act will be almost, if not quite, a dead letter.

By Clause 5, the local authority must prepare plans, showing the lands proposed to be taken; and this is important, as Clause 6 provides, that lands not included in the plan cannot be taken compulsorily. There is an important provision in this clause, that the local authority shall provide in their scheme "for the accommodation of as many persons of the working class as may be displaced" by the pulling down of the old houses. The new houses are to be erected in the same area as the old or in its vicinity, and proper sanitary arrangements provided. The words, "in the vicinity", might advantageously be made more elastic, as, in some cases, a cheaper and more healthy site might be found at a short distance from the old area.

The next clause provides for confirmation of the scheme by an application for the metropolis to a Secretary of State, and for other places to the Local Government Board, who shall direct a local inquiry to be held in the vicinity of the area reported on. If the report, after the inquiry, be satisfactory, the confirming authority may make a provisional order for the carrying out of the scheme, but this order is not to be of any validity unless it be confirmed by Act of Parliament. The confirming authority may also make an order for the allowance of all costs incurred in opposing the scheme, by the person or persons whose property is to be taken, and for the payment of all costs and expenses which they have themselves incurred, including that of the local inquiry, which are to be paid by the local authority. An arbitrator is to be appointed by Section 5 of the schedule, who has power under other sections to inquire into the value of the property taken, and to make his award, unless the parties shall agree as to price. If it be taken compulsorily, the value is to be based on the full market value. If the parties be dissatisfied with the award of the arbitrator, the person owning the property, or the local authority if the property be of greater value than £500, may have the matter tried before a jury.

Now, is it likely that an Act fenced in with so many provisions for increasing expense, and great obstructions to the acquirement of the property by the local authority, can ever be of much practical benefit? Surely, there can be no necessity to obtain an Act of Parliament for

compulsorily purchasing a property worth £500, or for appealing to a jury from the decision of the arbitrator for a similar amount and thus increasing enormously the expense, because it must be remembered that in every stage of the proceeding expenses of all kinds are incurred; and, as the value of the property is to be assessed upon the fair market value, the enormous rents obtained by letting separate rooms in unhealthy dwellings, unfit for habitation, would have to be taken into account in making an award.

There is one more important section of the Bill (No. 9) to which we must refer; and that is, that the Metropolitan Board of Works may, with the assent of a Secretary of State, appoint a qualified officer to make a "special inquiry" into the sanitary condition of any part of the metropolis. This is good, as far as it goes; but why should not the Board have power to appoint a medical officer permanently to make such an inquiry? Why should not a similar power be conferred on the Local Government Board for extra metropolitan districts?

There is no doubt that the Bill can be made very useful as supplementary to other prior legislation, provided that proper measures be adopted for removing the defects we have pointed out.

MEDICAL TITLES.

IF any apology were required for our returning to the subject of medical titles, it would be found in the large number of letters and communications which even yet continue to flow in upon us. It was not to be expected that our correspondents should all agree with us; yet, after a careful perusal of the communications upon the subject, we cannot say that our conclusions have been essentially modified. That the title of M.D. is the highest honour which an university has the power to grant in medicine; that those only who have, after a full curriculum extending over at least four winters, possessed themselves of the M.D. degree, are entitled to be styled doctors; that it is advisable to maintain, and even to elevate, the standard of examination for obtaining the degree; and that there is a great difference between the general term "doctor", as used by the public to designate medical men in general, and the assumption of such title by medical men themselves; such appeared to us, as they still appear, sound conclusions on the subject. And, further, as we felt strongly the hardship of excluding those who, from accident or other causes, had failed to take the degree in their student days, but who were willing to undergo later the trouble and expense necessary to obtain it, we suggested that, after proof was given that at least four winter sessions had been spent in the pursuit of medical science at a recognised school, such candidates should be admitted to examination by the universities, and should, if they passed the necessary examinations, have the degree conferred upon them. Such a course we thought, and still think, would preserve the rights of the existing graduates, who, at great cost in time, money, and labour, had obtained the university degree, while it would not arbitrarily exclude from the privileges of the degree gentlemen who had gone through a full curriculum, and who might prove themselves equal to the high standard of examination which, we think, should be maintained in order to its possession. It would serve the former purpose, because it would maintain the standard of qualification; and it would serve the latter, inasmuch as it is manifestly unfair to render irretrievable during the whole of after life a position which the accidents or necessities of youth had rendered it impossible to obtain then.

Many of our correspondents, we are glad to see, entirely concur in these views, while some of them concur in some but not in others. Perhaps that opinion on which agreement has been the least unanimous is the one in which we insist on a full curriculum of at least four winters at a recognised medical school before a candidate can obtain admission to the degree examination. But, while we respect the opinions of those who differ from us on this point, we would point out to them one or two reasons which seem to render it impossible that we should recede from it. First, then, we feel very strongly that the standard of qualification for the highest degree which the universities

can grant should be maintained at the highest possible point; and no means are, in our opinion, so well calculated to effect this purpose as prolonged attention to the groundwork of professional knowledge during a time when few or no distractions are offered by those business considerations which it is difficult to exclude in after-life. And, secondly, the present holders of the degree might justly, we think, consider themselves aggrieved were admission to a position equal to theirs offered on easier terms than those by which they themselves attained it. We are not insensible to the many anomalies pertaining to the various modes of granting the degree, nor do we fail to recognise the differences which undoubtedly exist as regards the value of nominally the same degree in different cases. We are painfully aware of these anomalies, and feel as strongly as any of our correspondents the indignation with which they refer to the selling of the degree, on the one hand, or to the too easy admission of graduates to its honours, on the other. Any proposal, indeed, which should secure a more thorough examination both in professional and general knowledge, would meet with our hearty support. The quality of the theses required from graduates, we are glad to see, is being improved year by year, which to some extent, no doubt, meets the latter requirement; and there can be no doubt that the standard of general knowledge required is much higher than it used to be. These are both steps in the right direction, and we hope that before long further advances will be made in the same line. But, while this is so, and while we are anxious to see the standard of graduation attain the highest practicable level, we see no reason for excluding from the honours of the degree those gentlemen who have gone through a full medical curriculum, and are able to prove that they possess sufficient information to entitle them to obtain it. The necessity of having some fixed rules to guide us in coming to right conclusions on such a matter as the present is apparent. We have given our reasons for holding the opinions we do. We hope we have given them temperately and with due consideration for all. And if in doing so, we have had to differ from some of the members of the profession, we have done so with reluctance, and under a sense of public duty.

In conclusion, we sincerely trust that some public action may before long be taken, with the view of settling this vexed question. One of our correspondents has suggested that a meeting of the profession might be summoned in London, and a memorial to the universities adopted, which could be afterwards signed by members who were unable to attend the meeting; or the subject might be brought forward simultaneously in several of the Branches of this Association. Some such course would seem to be desirable, and we think the universities would most probably receive with great respect a communication bearing the signatures of any considerable proportion of the profession. In any case, some of the evils of the present systems of graduation are so clamant, that we should welcome any proposal which should offer to evolve some order from the confusion at present reigning over the whole subject of medical titles.

THE VASO-MOTOR APPARATUS.

IN an able series of lectures recently published, M. Vulpian has discussed, with great detail, the anatomy and functions of the vaso-motor apparatus of nerves—that *terra incognita* of physiology and medicine. M. Raymond, in the *Progrès Médical*, page 65, gives an interesting account of M. Vulpian's views, which will incite many to a study of his work. M. Vulpian, he says, gives clinical proofs of the influence exercised by the lesions of the great sympathetic nerve on the vascular system; he afterwards enters on the question of the vaso-dilator nerves. Calling to mind that the vessels are provided with muscular fibres, arranged in an annular form, and whose contraction can only occasion a diminution of the calibre of the vessel, M. Vulpian shows that experiment has taught a singular and incontestable fact, the existence of nerves whose excitation brings on dilatation of the vessels under their influence. These nerves, of which we owe the knowledge to Claude

Bernard, are named *vaso-dilators*: whilst the others have received the name of *vaso-constrictors*. M. Claude Bernard demonstrated this fact whilst repeating Ludwig's researches on the submaxillary gland. He demonstrated as to the anastomotic filament furnished to the lingual nerve by the chorda tympani, that the action of the lingual or of the glandular filaments which spring from this nerve is due, an action which consists in the arrest of the salivary secretion when the lingual is cut, and in the continuation of the secretion when the peripheric end of the cut lingual nerve is irritated: the chorda tympani is therefore a type of vaso-dilator nerves.

Claude Bernard has searched for the existence of other vaso-dilator nerves. It has seemed to him that the auriculo-temporal branch of the fifth nerve, which anastomoses with the facial, had a dilating action on the vessels of the ear, and the same was the case with the nervous filaments surrounding the carotid. Claude Bernard has further pointed out the pneumogastric as determining a dilatation of the vessels of the breast, a fact which is denied by M. Vulpian. The chorda tympani does not exercise its dilating action on the vessels of the submaxillary gland alone. M. Vulpian has demonstrated, by irrefutable experiments, that this action is extended to the vessels of the tongue.

Nerves described by M. Eckhard under the name of *nervi erigentes* are also vaso-dilators. They spring from the sacral plexus, and, with the pudic nerves, proceed to the corpus cavernosum. These latter have not any action with regard to erection, whilst the former produce it; it is probable that the irritation of the erector nerves reacts rather on the arterioles than on the areolæ of the corpus cavernosum. M. Goltz has lately endeavoured to show that the nervous centre of the erector nerves is situated in the lumbar region of the spinal cord.

Many hypotheses have been proposed to explain the action of the vaso-dilator nerves. Heidenhain's experiments have shown that atropia paralyses the action of the chorda tympani on the secretion of the submaxillary gland; and, on the contrary, leaves intact the influence of this nerve on the vessels of the gland. M. Vulpian thence concludes that there are secretory nerves; and, indeed, how can the results of this experiment be accounted for, if the existence of these secretory nerves be not admitted? These experiments annihilate the hypothesis of the attraction of blood by the tissues. Must we see, in the action of the vaso-dilators, a phenomenon like that known in physics under the name of the *interference of light*? must an inhibitory action be admitted? M. Vulpian has adopted this last view, always making the reserve, that the vaso-dilator nerves only act on the vascular tonus by their communication with the nervous ganglia which regulate the vaso-dilators.

The next question is, as to the origin of the vaso-motor nerves. They have their principal roots in the spinal cord; but their mode of origin is not precisely known, notwithstanding the opinion of M. Jacobowitch. It results, from this relation of the vaso-motors with the spinal cord, that lesion or irritation of the spinal cord must have a great influence on the nerves, and, consequently, on the vessels; this is indeed the case, and the partial lesions of the medulla give rise to vascular constrictions or dilatations in the parts in relation by their nerves with the region of the cord where the lesion exists, and each of these modifications results from an irritation, made evident either by a dilatation or a constriction, whence the variability of the phenomena observed. It is now easy to understand how irritation practised on the surface of the body, for instance, acts by reflex action, passing by the spinal cord to the dilator or to the constrictor nerves. Here we find the explanation of a host of phenomena; for instance, of the reflex vascular dilatations invariably produced whenever the subcutaneous cellular tissue, the muscles, etc., are laid bare. It is a known fact, that these parts become the seat of a very evident congestion, and dilatation is not confined to the exposed region.

The opinion which has been adopted by a large number of physiologists, that there is only one vaso-motor centre, the medulla oblongata, is rejected by M. Vulpian on the ground of his experimental researches. In his opinion, there are a series of vaso-motor centres in the bulb, and specially in the spinal cord. If it be so, the question arises, whether

the spinal cord and the medulla oblongata are the principal foci where the vaso-motors originate, and the only ones. Experiment has proved that the sympathetic ganglia may also be the seat of origin of the vaso-motor nerves and centres of reflex actions for these same nerves.

M. Vulpian afterwards shows the existence of the vascular tonus—that state of semicontraction necessary to the small vessels, and which gives a certain elasticity to their muscular coats. With regard to the question as to the mechanism by which the spinal cord exercises its action on the heart and vessels, M. Vulpian takes up the history of the subject to the discovery of Ludwig and Thiry, and establishes a very important physiological part of the question; that is, with regard to the depressor nerves. It is now well known that the spinal cord acts on the heart by the medium of the vaso-dilator and vaso-constrictor nerves, by augmenting and diminishing the arterial tension. These facts lead him to study the influence of the vaso-motor nervous system on the pressure of the blood, on absorption, on erection, on reflex congestion, on erectile tumours, and finally on the glands. The action of the nerves on the glands puts the importance of the physiological action of the vaso-motors in full prominence, explains many hitherto unknown actions, and will probably throw light on many more. The studies contained in this volume relative to the action of the nerves on the secretions, on the stomach, intestines, kidneys, and liver, are proofs that these expectations are by no means unwarrantable.

DR. GERVIS has been appointed Obstetric Physician and Lecturer upon Midwifery at St. Thomas's Hospital in succession to Dr. Barnes.

SIR W. STIRLING-MAXWELL has just issued a reproduction in lithograph, privately printed, of the celebrated anatomical plates of Vesalius, published at Venice in 1538, folio.

A STATUE of Dr. Wells, "the discoverer of anæsthesia", is to be cast in bronze, in one piece, and set up at Hartford, just as it comes from the mould.

AT the tercentenary anniversary of the University of Leyden, the honorary degree of Doctor of Medicine was conferred on Professor Bunsen of Heidelberg, and the degree of Doctor of Mathematics and Physics on Professors Brücke of Vienna, Gegenbauer of Heidelberg, von Siebold of Munich, and Traube of Berlin.

THE usual monthly meeting of the Medical Officers of Health will take place this (Saturday) evening, at the Scottish Corporation Hall, Crane Court, Fleet Street, when Dr. G. Ross will read a paper entitled "An Analysis of the Bill, introduced by the Home Secretary, for Facilitating the Improvement of the Dwellings of the Working Classes".

THE SANITARY CONDITION OF THE UNIVERSITIES.

THERE is great public reason to desire that the question of the sanitary condition of our universities be not allowed to drop. There is good ground to fear, that there will be some more serious epidemic than there has yet been, if public opinion be not roused to the extreme importance of placing our young men at the universities in more favourable circumstances as regards health than they now enjoy. We have no accurate statistics to quote; but we are constantly being informed, that the men at Cambridge complain of being more or less ill. And now, we again hear, there is typhoid—the captain of one of the leading boat-clubs being reported to have been stricken with that disease. It would appear almost of less consequence that there should be an occasional sporadic case of severe illness and death; but what appears to us so grievous is, that without being ill enough to be laid up, or send for a doctor, the men with one accord—so far as our experience goes—complain of the depressing effects of the air at Cambridge. And how can it be otherwise, while they live over a cesspool extending all under and about the town? The drainage, as we have shown, is

discharged in "the heart of the town" into the Cam, which is no more than a vast open sewer without any fall. We are told, by men who ought to know, that Oxford is as bad as Cambridge. When the authorities of these places are asked, they will probably answer, that the proportion of typhoid is not excessive; but they do not take into account the debilitating effect of a foul atmosphere, that does not necessarily result in that culminating effect. Our universities, instead of being models of sanitary arrangements, appear to be the very reverse. If they cannot find a proper outfall for their sewage, they had best adopt earth-closets, or the old-fashioned cesspool, with duly appointed scavengers. The matter appears to us one of great national importance, and affecting the best of the future generations of Englishmen. We hope that it will receive very early and serious attention.

CREMATION.

THE Council of the Cremation Society have, we learn, made a tangible progress towards accomplishing their object. A piece of ground has been secured for the erection of a building in which the religious rites can be performed prior to the incinerating process. The estimated cost of the proposed building is £3,500, towards which £1,000 has been promised. Further subscriptions are requested. Every information will be given by the Secretary, Mr. W. Eassie, C.E., 1, Great Winchester Street, E.C.; and subscriptions will also be received by Sir Samuel Scott, Bart., and Co., Cavendish Square, London.

INCREASE OF LUNACY.

A STARTLING statement was lately made at the meeting of the Manchester Board of Guardians by Mr. Macdonald, the clerk, in regard to the increase of pauper lunacy. In 1851, the number of lunatics in the workhouse and asylum was 231, and now there are no fewer than 625, or an increase of 170 per cent.; and this in spite of the fact that the population of the township had decreased to the extent of 13,000 persons during the last twenty-four years. The percentage of pauper lunatics to the entire population, it was said, had trebled, and the cost was proportionately great. In 1851, only £3,800 was paid for their maintenance, but now the ratepayers have to disburse annually the sum of £13,320. This shows an increase of 250 per cent. in cost, and a more serious item in the local relief expenditure it would be hard to find.

THE MANAGEMENT OF HOSPITALS.

AT an adjourned meeting of the quarterly court of the Radcliffe Infirmary, held February 16th, the following motion was proposed by Dr. Rolleston, seconded by Edward Chapman, Esq., M.A., and carried *unanimously*. That the Government be memorialised to the effect that it is expedient, in the interests of the efficient management of hospitals and infirmaries, to make it within the competence of the managing committee of any such institution, to avail themselves of the services and advice of the sanitary inspectors appointed to act from the Local Government Board, when they judge it to be necessary to do so.

THE FEVER EPIDEMIC IN LONDON.

ACCORDING to the last returns from the pauper fever-hospitals of London, the fever epidemic among that class is diminishing; but it does not show a corresponding decrease among the other classes, for Dr. Broadbent, at the meeting of the Fever Hospital governors this week, reported that the classes of patients for whom the institution in the Liverpool Road, Islington, is now set apart—as tradesmen, servants, artisans, and the classes above them who require isolation—do not decrease in number. In the past year, 384 patients were admitted, nearly all of whom came in the last month of the year, and a very large number of these were admitted free; and while, on the one hand, the institution prevented the spread of these highly contagious diseases, it saved the respectable classes from having to face the alternative of treating the disease at home or sending their friends to pauper asylums. Dr. Buchanan and Dr. Thorne Thorne spoke of the urgent need which

existed for an asylum of this character, which was for nearly seventy years the only fever hospital for all London; and in regard to the diminished income from subscriptions and donations pointed out at the meeting, it was explained that there had been a falling off since the establishment of the Sunday Hospital Fund, from which the institution, however, derived no benefit. The Earl of Devon was re-elected President, with thanks for his past services; Lord Derby, the Archbishop of Canterbury, the Bishops of London, Ripon, and Winchester, Lord Monteagle, Dean Stanley, and Sir William Jenner, were elected Vice-Presidents; Mr. Hugh Owen, honorary secretary; and Mr. T. H. Hills, Mr. Robinson, Mr. Dimsdale, Mr. F. W. Low, and other gentlemen were added to the committee.

HUNTERIAN SOCIETY.

THE following gentlemen were elected on February 10th for the Session, 1875-76. *President*: W. Sedgwick Saunders, M.D. *Vice-Presidents*: R. U. Wallace, M.B.; E. Clapton, M.D.; H. Gervis, M.D.; H. G. Sutton, M.B. *Treasurers and Trustees*: T. M. Daldy, M.D.; H. I. Fotherby, M.D. *Librarian*: P. L. Barchell, M.B. *Secretaries*: F. Gordon Brown, Esq.; Warren Tay, Esq. *Council*: J. E. Adams, Esq.; Robert Barnes, M.D.; F. M. Corner, Esq.; F. Daldy, Esq.; R. Fowler, M.D.; J. Greenwood, M.D.; D. De Berdt Howell, Esq.; J. McCarthy, M.B.; P. H. Pye-Smith, M.D.; W. Rivington, M.B., M.S.; A. H. Smee, Esq.; W. Toulmin, Esq. *Auditors for 1875*: J. E. Adams, Esq.; C. T. Blackman, Esq.; D. De Berdt Howell, Esq.; W. Humphreys, Esq.

THE STATISTICAL SOCIETY.

THE Council of the Statistical Society of London invite competition for an essay on "The State of the Dwellings of the Poor in the Rural Districts of England, with special regard to the Improvements that have taken place since the middle of the Eighteenth Century; and their Influence on the Health and Morals of the Inmates." The successful candidate will be awarded the Society's Howard Medal for the current year. The essays will be received until June 30th, and the medal awarded in November next. The competition is an open one. Full particulars of the conditions can be obtained of the Assistant-Secretary, 12, St. James's Square.

JUBILEE OF A GERMAN PROFESSOR.

THE fiftieth anniversary of the appointment of Dr. Jungken, professor of surgery in the University of Berlin, was celebrated on January 17th. His Majesty the Emperor conferred on him the star of the Order of the Crown of the second class. Unfortunately, the feeble health of Professor Jungken prevented him from being present at the festivities in honour of the rare and interesting event.

SUGGESTIONS ON DIPHTHERIA.

THE Public Health Association of New York have, in consequence of the prevalence of diphtheria in that city, taken the subject into consideration with a view of tracing the cause of the outbreak and of devising some remedy. The conclusions at which they arrived are the following. 1. When diphtheria had gained a foothold in any city or populous neighbourhood, it selects certain localities in which its persistence is specially marked; and its persistence, as shown by repeated outbreaks or continual prevalence, seems to hold an important relation to certain conditions of soil, drainage, and sanitary wants of dwellings, which admit of preventive measures. 2. The extension of the disease from one individual to another, and to entire households or families, and from family to family, and from place to place, are facts so well proved in the history of the disease, that the entire separation of the sick from the well—at least, of children sick with this disease from all others, should be regarded as a first-rate sanitary duty. 3. The immediate sanitary, as well as perfect medical care, of every family exposed to it, seems to be a duty required by every consideration of humanity and public health. 4. A complete and exact record of diphtheria as it prevails in any locality, is a duty of much importance to society; and

that, for the purpose of promoting the successful discharge of this duty to society and the medical profession, the Public Health Association of the city of New York, respectfully submits the following resolution as embodying its views upon the subject: "That every board of health, every county and city medical society, and every practitioner of medicine in the State of New York, is most respectfully urged to cause a correct record to be prepared concerning the beginning, progress, local, domestic, and hygienic conditions under which this disease appears, progresses, and is brought under any degree of sanitary treatment."

THE GERMAN ASSOCIATION OF NATURALISTS AND PHYSICIANS.

EXTENSIVE preparations are being made in Gratz for the reception of this learned body. The secretary, Professor Rollet, reported at a recent meeting of the reception committee that 20,000 gulden (£2,000) had already been raised. The Ministry of Instruction contributed half the sum, and the provincial council and the municipal council of Gratz each 500 gulden.

THE PROVIDENT SYSTEM.

WE are informed that, in consequence of the trial of the partial provident system at the St. Marylebone General Dispensary, during the past six months proving a success, it was decided at a general meeting of Governors on the 10th instant, to make this principle permanent.

SALICYLIC ACID.

ATTENTION has been directed recently to the antiseptic qualities of this product, which can now be produced by synthetic chemical processes. Salicylic acid is slightly yellow in colour, taking the form of very fine crystals, which are readily soluble in alcohol and ether, and in hot water, but not in cold water. The melting point is 318 degs. Fahr. If heated rapidly, it is resolved into carbonic and carbolic acids. Under slow heat, it sublimes without decomposition. The composition and the qualities of this acid led Professor Kolbe to infer, what has since been found true by Professors Knapp, Neugebauer, Thiersch, and others, that salicylic acid possesses valuable antiseptic qualities as a preventive of fermentation and putrefaction. In many respects, salicylic acid is, it is stated, preferable to carbolic acid, from its absence of smell and its not unpleasant taste. It is applicable for either external or internal use, in rather large doses, without injurious effects; and it has been employed beneficially in surgical cases. The great value of the acid will be its preservative effects on provisions of every description—a purpose to which carbolic acid is unsuited. Professor Neugebauer's experiments showed that a small quantity of salicylic acid was not only sufficient to prevent the second after fermentation of wine and consequent muddiness which this produced, but that it also prevented the formation of fungi in the casks. Professor Kolbe's experiments proved, that half a *gramme* of the acid was sufficient to check the fermentation produced by 5 *grammes* of yeast in a solution of 120 *grammes* of sugar dissolved in one *litre* of water. From these data, a fair estimate of the quantity to be used for the preservation of champagne, beer, and syrups, intended for exportation, can be formed. Another important use which Professor Kolbe suggests is its application to the prevention of decomposition of water on board-ship, by the addition of the acid in the proportion of 1 to 200,000, by covering the bung-hole of the casks with cotton-wool steeped in salicylic acid; the preservation would be effected by the filtration of the air. Provisions could also be preserved by the application of the acid on the surface. It was found that the process of curdling in milk was retarded for thirty-six hours, by the addition of 6.04 per cent. of salicylic acid. These effects were obtained from free salicylic acid, and not from any of its salts. Professor Kolbe suggests, also, that the acid is peculiarly adapted for use as a toilet requisite for dentifrices, and as a preventive of the disagreeable odour caused by fetid perspiration, without producing any injurious effects. For the still more important purposes of surgical dressing, Professor Thiersch and Dr. Fehling, who have used it somewhat extensively, report that it arrests the smell of putrefaction without

producing any appreciable inflammation; and that a solution of 1 part of salicylic acid, 3 of phosphate of soda, and 50 of water, will promote the growth of skin over granulating surfaces. In surgical operations, a spray of acid and water, in the proportion of 1 to 300, has been used, and the wound dressed with wadding soaked in the solution. In the lying-in hospital at Leipsic, salicylic acid is used instead of carbolic, in vaginal diseases, and for dressing puerperal ulcers. As the acid is soluble in fatty oils, it can be used, like carbolic acid, for Lister's bandages. Its use internally has been suggested for those diseases which are contracted from contagion. From personal experiment, Professor Kolbe found that he could take from 1 to 1.25 *grammes* of the acid daily, without the least inconvenience or disturbance to his general health. Further experiments are being made in Germany as to the properties of salicylic acid and its combinations. Messrs. Domeier and Co., of 3, Botolph Lane, are the agents for the United Kingdom, and will forward full particulars to anyone desiring further information.

RELATION OF SEX TO MORTALITY FROM VARIOUS CAUSES.

FROM a statistical summary of the mortality in Berlin during the five years, 1869-1874, it appears that there is a certain constancy in the resistance to individual causes of death on the part of one or the other sex. In Berlin, there are more men than women; but the numbers of deaths in the two sexes, from infectious disease, was in the inverse ratio, being 9,193 men to 9,570 women. On the other hand, the male sex has furnished the majority of deaths from all other causes, with the exception of parasitic diseases and disorders of development and putrefaction. The deaths from diseases of the nervous system were 12,237 men and 9,822 women; from diseases of the respiratory organs, 18,818 men and 14,665 women.

THE ABUSE OF HOSPITALS: MEMORIAL TO THE COMMITTEE OF COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.

SINCE we last alluded to the memorial on the subject of the abuse of hospitals, which is now before the profession, the following names have been added to the list of signatures: Dr. Murchison, F.R.S., Mr. Spencer Wells, Mr. J. C. Wordsworth, Mr. Critchett, Dr. Burdon Sanderson, F.R.S., Mr. Henry Power, Dr. James E. Pollock, Dr. Clapton, Dr. Gustav Murray, Dr. H. J. Sanderson, Mr. W. Adams, Mr. Jabez Hogg, Dr. Berkart, Dr. Morell Mackenzie, Mr. George Cowell, Mr. Nettleship, Dr. Percy Boulton, Dr. Arthur Ransome (Manchester), Mr. G. S. Madeley, Mr. Robert Hall, Mr. T. C. Beatty (Seaham Harbour), Mr. T. C. Beatty, Junr., Mr. Thomas Taylor, Mr. Hutchins Williams (Lee), Mr. Chataway (Kingland), Dr. W. Haining (Chester), Dr. G. K. Poole (Anerley), Dr. S. T. Smyth (Forest Hill), Mr. Holderness (Huntingdon), Mr. John Manley (West Bromwich), Dr. John Johnston, Dr. Madden (Torquay), Dr. Macreight (Torquay), Dr. Paget Blake (Torquay), Mr. W. Pollard (Torquay), Mr. J. Pollard (Torquay), Dr. Spencer Thomson (Torquay), Dr. W. B. Dalby (Torquay), Mr. Edward Bean (Torquay), Mr. S. Rhind (Torquay), Mr. Paul Karkeek (Torquay), Dr. Thursfield (Leamington). The memorial we pointed at length on January 2nd. Gentlemen who are desirous of signing it, are requested to communicate with Dr. Meadows, 27, George Street, Hanover Square, or with Mr. Fairlie Clarke, 12, Mansfield Street, Cavendish Square.

THE CHARITY VOTING REFORM ASSOCIATION.

THIS Association held its first annual meeting on Thursday last, the 18th instant, under the presidency of Lord Lytton. The report states that a strong public feeling has been created in favour of the object in view, as is proved by the fact that the Association already numbers 2,736 members. Among these are the names of not a few of the leading philanthropists of the day, and we are glad to observe that the medical profession is well represented. In speaking of the various steps which are being taken to advance the desired reforms, the report mentions that "the committee is in course of issuing a form of memorial to the subscribers to the Medical Benevolent College, commencing with those who have joined this Association (upwards of 400 in num-

ber). This will give those who are with us an opportunity of praying the Council to make such alterations in their rules as will relieve candidates, as well as their relatives and friends, from the hardships to which they are exposed under the existing system.

CORONERS.

MR. R. BAILEY WALKER, in a paper recently read before the Manchester Statistical Society, alluded in strong terms to the importance of these officers. He said, "There can be no doubt that there are few more valuable public officers than coroners. They are, however, often an object of suspicion and dislike to local authorities, whose neglect of duty leads to much waste of life, and who, therefore, naturally object to a system of inquiry into the causes of death."

JABORANDI.

DR. FRANZ RIEGEL has lately administered this drug to several patients in the town hospital at Cologne, and has published an account of the results. The cases which he reports are ten in number, viz., exudation in the right pleura; chronic pneumonia, with acute nephritis; influenza (two cases); chronic muscular rheumatism (two cases); cirrhosis of the liver, with varicose veins in the leg, and chronic rheumatism; lead-colic (two cases); and convalescence from acute articular rheumatism. Dr. Riegel says that he thinks he does not go too far in asserting that jaborandi is an excellent diaphoretic and energetic sialagogue. Although it was in most of the cases difficult to produce sweating, even by the use of warm baths, etc., in every one the administration of the jaborandi was followed by abundant perspiration. To some of the patients, a hot bath was given, for the sake of comparison, some days before or after the jaborandi; and they declared that they preferred the jaborandi, on account of the less amount of inconvenience which attended its use. The sialagogue effect was distinctly present in eight of the cases; in two it was not observed; perhaps, however, Dr. Riegel suggests, there was an increased flow of saliva, but it was swallowed by the patients. (The two cases were, one of influenza, and one of chronic pneumonia.) There was no evidence of any notable increase of the bronchial secretion. The ingestion of the jaborandi was in no case followed by a great primary elevation of temperature, such as occurs when perspiration is induced by restricting the loss of heat. Observations, by means of the sphygmograph, were made on the pulse in two cases; from the results of which Dr. Riegel infers that jaborandi produces relaxation of the arteries, and increased power of the heart. As after-effects, hiccup and eructation were observed, sometimes also vomiting; these, perhaps, being consequences of swallowing the saliva. In two cases, slight *malaise* was produced; and in two there was some faintness, with transient *musca volitantes*, and disturbance of vision. There was frequently an increased desire to pass urine. All those after-effects were moderate in degree and soon passed off; so slight indeed were they, that the patients always declared themselves ready for a repetition of the dose. The preparation used by Dr. Riegel was the powdered leaves, in packets weighing about a drachm, and marked as "One dose of Dr. Coutinho's jaborandi". In one case he divided the dose into two; in all the others he gave the whole quantity after infusing it for a quarter of an hour. He promises to communicate the results of further experiments which he is making. M. Vulpian finds that the diaphoretic action of jaborandi is much reduced by the previous administration of atropia.

SCOTLAND.

DR. THOMSON OF DALKEITH.

WE regret to have to record the loss of Dr. Thomson of Dalkeith, a well known and prominent member of the profession. Dr. Thomson, while enjoying an extensive practice in Dalkeith, kept up his connection with Edinburgh and its institutions. He was a regular attendant at the Societies, and during the years 1871 to 1873 filled the chair of President of the Obstetrical Society. His many genial qualities had secured him a host of friends, who now regret his loss.

MR. CROSS'S BILL, AND HOUSE ERECTION IN GLASGOW.

MR. CROSS'S Bill in Parliament for the Improvement of the Dwellings of the Working Classes is naturally exciting considerable interest in Glasgow. It is surely honourable to the enterprise and enlightenment of the city, that this general and Government measure is moulded on that obtained by Glasgow a considerable number of years ago. The preamble of the Government measure is copied almost word for word from the Glasgow City Improvement Bill. Of course, the peculiar circumstances of Glasgow rendered a measure of this kind more urgent than in any other of our large cities, but it is surely satisfactory to find that the far-sightedness of the authorities has thus, in a manner, gained the approval of the country at large. It is to be hoped that Mr. Cross's Bill will be extended to Scotland. In Glasgow, it would considerably facilitate the future action of the authorities, whose work in the improvement of the city is by no means completed. The application of the Act to Glasgow would be an advantage in two respects. In the first place, it would enable the city to borrow money at 3½ instead of 4 per cent., and this would be a saving of several thousands annually to the community. Then it would enable the city to deal much more directly with any parts of the city requiring interference, that is, without any special application to Parliament. While powers are thus being conferred, by means of which the evils of past generations are being in part remedied, it is beginning to be all the more felt, that there are no powers in existence to prevent the production of evils only less in degree at the present day. No authority in Glasgow seems to have any power to compel builders to leave spaces for air around the houses erected. When it is remembered that in Glasgow most of the houses are four storeys high, and that these are often built in the form of a square, facing four lines of street, so that within this deep square box the air can only stagnate, it is evident that the arrangements for ventilation must be exceedingly defective. But, added to this, the inside of the square is often filled up with a fresh building or buildings, so that the ventilation is still further prevented; and yet no authority seems able to hinder such a method of procedure. Dr. Russell, the medical officer of health, has lately published a paper which brings some of these points before us in the shape of actual figures. In this pamphlet, he states: "No one can comprehend the importance of this matter of house construction to the future of Glasgow, unless by placing clearly before his mind two facts: (1) the enormous number of dwelling-houses being erected from year to year—since 1866 no less than 26,794; and (2), above all, the small size of those houses. Actually, of those 26,794 built since 1866, 25 per cent. were houses of one apartment, and 50 per cent. houses of two apartments, leaving only 25 per cent. for all sizes above two apartments, and of these 18 per cent. were houses of three apartments. One cannot be too anxious or exacting concerning the ventilation and general arrangements of such clusters of small houses." The remedy for all this may be difficult to find. Some would seek for it in an extension of the powers of the Dean of Guild Court, a court to which the plans of all houses to be erected must be submitted. If this court had power to insist on certain spaces between houses, and precautions for thorough ventilation, much would be effected. But it is felt that at the bottom of all this overcrowding in Glasgow is the high figure to which the price of land has risen. No doubt, the action of the city improvement trust has had something to do with this, by displacing a considerable portion of the community, and rendering the demand for houses unnaturally great. So long as land in the centre of the city is sold at £30 per square yard, and even in the outskirts brings not less than £1, the tendency must be to erect houses covering as small a space as possible. It is beginning to be felt, that the only effectual method of remedying this is for the authorities to obtain the power of acquiring land to be held in trust for the community. This, if properly checked, will offer two very obvious advantages. The corporation would buy up, let us say, some tracts of land around the city, and, when the time came, they would be able to free or sell portions at a moderate figure, their object not being a pecuniary one. The builder would thus acquire ground at a price which would

enable him to spread out his tenements. Then the authorities, as proprietors of the land, would be able to bargain with the builders as to the ground-plan of the buildings: they could require that free spaces should be left, and that thorough ventilation was kept in view. There is no doubt at all, that the minds of the intelligent citizens of Glasgow are coming round to some such view as this. It is only a pity, that while people are considering the evil is going on. We know of one suburban burgh near Glasgow, which is yet in great part to build, but in which buildings of the worst possible description are being run up, although the authorities would fain have it otherwise. They have no power, however, to interfere, except within narrow limits, and meanwhile the evil grows.

THE WEATHER AND THE DEATH-RATE.

At a meeting of the Scottish Meteorological Society held last week, an interesting paper was read by Dr. Arthur Mitchell, Commissioner in Lunacy, on the Effects of the Weather of the last three Months on the Death-Rate. His remarks principally applied to London, as it always yields the most suitable materials for inquiries of the kind, because of the great number of persons who live under substantially the same conditions of climate, while the published facts regarding it are fuller than the records of most other places. Moreover, the results yielded by other parts of the kingdom, both rural and urban, are very similar. The element of the weather he took into consideration was temperature, which was the one having the closest relation to the death-rate, and the one which, in the three past months, had exhibited special phenomena. The first three weeks of November oscillated now above and now below the mean temperature; but the last week showed a fall of 8.4 degrees below the average. This great depression was maintained over the whole of December, the last week showing a mean of 28.4 deg. Fahr., or 10 degrees below the average. In January, there was a considerable rise in the temperature, and the weather was warmer than average January weather by from 4.5 to 7 degrees. Such being the state of the temperature, what were the results upon the health of the population? Were any diseases specially frequent, and any ages specially affected? The death-rate generally was unusually high. Dr. Mitchell proceeded to show that certain diseases tended more than others to swell the mortality. Those which were usually most fatal in cold weather showed a high increased fatality. This was most marked in the diseases of the respiratory organs. Very striking is the inverse relation between temperature and the deaths from bronchitis. During these thirteen weeks, the deaths from this disease were 55 per cent. above the average. Pneumonia gave an increase of 32 per cent.; in this case, the effects are not so quickly seen as in bronchitis, and manifest themselves longer. Pleurisy, which in general is much less fatal than the other two, showed a higher percentage of increase on the nominal death-rate than any other disease—viz., 110 per cent. Deaths from asthma were also much increased—to as much as 60 per cent. above the average. Among other diseases, rheumatism, heart-disease, Bright's disease, and erysipelas, had their maximum during the last six weeks of 1874. Rheumatism showed an increase on the ordinary rate in these months of 94 per cent.; Bright's disease, 75 per cent.; erysipelas, 65 per cent.; and diseases of the heart, 27 per cent. The influence of low temperature on the fatality of these diseases is more marked than their general relation to weather would lead us to expect. In relation to phthisis, there are ordinarily two maxima of fatality: one in November; and the second, more marked, in March; and, though commonly looked upon as a pulmonary disease, it did not agree with the other pulmonary diseases mentioned in its behaviour with relation to temperature. This relation was preserved in the three months in question, for the increase of mortality from it was only 5 per cent. above its constant. It appears that dryness must be added as an attribute to cold to make it act most perniciously on the subjects of phthisis. Some researches made by Dr. Mitchell and Mr. Buchan showed, in relation to this disease, that, when tuberculosis kills by the lungs, the distribution of deaths over the year approaches that of other lung-

diseases, but is distinct; when by the abdomen, the distribution of deaths is nearer to that of abdominal diseases, but here also has some distinctions. In relation to the question whether any diseases were influenced by the cold weather of these months, he found some, but very few; and these were among those which are most fatal in the hottest months of the year—as, for instance, diarrhoea, which showed in these three months a decrease of 10 per cent. in its mortality. To the third question, as to the influence of the weather upon different ages, his answer would, he thought, excite general surprise. The young suffered little, the middle-aged considerably; but the old bore the great burden of the injury. Children below five years showed an increased mortality of only 6 per cent.; between twenty and forty, it rose to 15 per cent.; between forty and sixty, to 24 per cent.; over sixty, to 32 per cent. Thus, the general statement that the cold weather proved very fatal to the very young and very old, was only true of the latter. Summer is the most fatal time to children; great heat, not great cold. The reverse of this is true in adult life.

A CENTENARIAN.

THE death of a centenarian is reported from Cambuslang parish, near Hamilton. The deceased was a widow, Mary Shearer, said to have reached the great age of 105 years. She was a person of vigorous intellect, and retained possession of all her faculties till within a few months of her death. Her descendants number over 170.

IRELAND:

MR. MACDOWEL, at the recent examinations in the University of Dublin, gained first place both in the medical and surgical examinations for degrees; and, in accordance with a regulation of the Board, and as a recognition of merit, the surgical degree (Master in Surgery) was conferred on him *stipendiis condonatis*.

DISEASED MEAT: SEVERE PENALTY.

A SAUSAGE-MAKER in Dublin last week, named Sothorn, was prosecuted at the instance of the Public Health Committee for having in his possession a quantity of pork—about nine stone—so diseased as to be utterly unfit for human food. It was proved in evidence that the pig had been affected with scarlatina; and the presiding magistrate, it being a first offence, fined the delinquent in the full penalty of £20. If it had not been for the vigilance of the sanitary officers who seized the unsound food, most probably in a short time it would have been highly seasoned and sold as sausages to the poorer classes. No pecuniary punishment is too severe for an offender of this sort, and it may be doubted whether the penalty of a fine is the right one.

COLLEGE OF PHYSICIANS: NEW CHARTER.

LAST week, a meeting of the College was called, and the following resolution passed: "That, if the charter be granted giving the College the power of instituting an Order of Members, it is the opinion of the College that any licentiate admitted before the granting of the charter, who may desire it, may be transferred to the Order of Members without additional expense." This resolution will probably remove the opposition of those licentiates who objected on principle to pay anything for being elected to the higher order.

CHAIR OF CHEMISTRY, UNIVERSITY OF DUBLIN.

DR. J. EMERSON REYNOLDS has been appointed by the Board of Trinity College to this professorship, vacant by the resignation of Dr. Apjohn. The lectureship on Chemistry in the Royal College of Surgeons, which Dr. Reynolds held, and which he must now resign, will be filled up on March 18th, when the President, Vice-President, and Council will proceed, according to the provisions of the supplemental charter, to fill the vacancy. It is believed that Dr. Charles A. Cameron, City Analyst for Dublin, and Lecturer on Chemistry at the Ledwich School of Medicine, will be appointed in Dr. Reynolds's place.

THE HUNTERIAN ORATION.

THE Hunterian Oration, now biennially delivered in the theatre of the Royal College of Surgeons, in memory of John Hunter, the founder of the collection bearing his name, was delivered on Saturday by Mr. Frederick Le Gros Clark, F.R.S., President of the College. This discourse does not appear to lose any portion of its attractiveness, judging from the very large attendance assembled to do homage to the memory of Hunter, and to show their respect to the orator.

The large portrait of Hunter, considered the *chef d'œuvre* of Sir Joshua Reynolds, had been brought from the Council-room, was suspended in front of the audience, and subsequently alluded to by Mr. Clark, who, after paying a short but eloquent tribute to the memories of some of the most distinguished members of the College who had passed away since the last oration—Partridge, Jordan, Bishop, Cutcliffe, Turner, Wormald, Wyatt, Cutler, Swan, Martin, and Kiernan—men who, in the words of the founders of the oration, "have contributed by their labours to the improvement or extension of chirological science"—proceeded to address his audience to the following effect.

After a few observations as to our indebtedness to Hunter for exemplifying, in all his pursuits, the true spirit of our greatest of modern philosophers, he said he did not suppose that Hunter had studied Bacon, and yet there never was a more faithful exponent of the inductive method of reasoning than Hunter. His perception of its value in the investigation of the works and laws of Nature was intuitive; his foundations were broad and deep; and caution and vigour were conjointly exercised in raising his superstructure. Every line he wrote, every preparation he made, attest its truth. After acknowledging the services of all those engaged in the onerous trust of the vast collection, Mr. Clark briefly referred to an important matter which for a considerable time past had occupied the earnest attention of the Council, adding that the present was a crisis in the existence of the College. Through good report and evil report, the College had advanced to eminence and to usefulness commensurate with its prosperity, and was now about to surrender an independent agency it had long exercised, to co-operate with other public bodies in constituting an Examining Board for a qualification to practise. He sincerely trusted that this arrangement might realise all that was expected of it; for the past history of the College and its early struggles for independence, its noble aspirations, its great achievements, were most dear to him. Who should forecast its future history, when that independence was gone? Whatever it might be, the College would need the support of all holding the diploma, and claim the chivalrous exercise of their franchise by the constituents of an institution which, in its traditions and as a home and nursery of scientific surgery, was second to none in the world.

Mr. Clark showed how much Hunter's writings had influenced the labours of his successors in the development of surgery, by raising it from an empirical handicraft to a scientific art; for he exemplified, in a way and degree which had never before been attempted, the natural association, the necessary alliance, between physiology, pathology, and the treatment of disease; and might justly claim, by his logical demonstration of this relation, to have stimulated the cultivators of medical as well as of surgical practice to seek for a more just interpretation of the phenomena of disease, and thus to conduct its management on more enlightened principles. The truly philosophic example of Hunter was the highest and most lasting title he had established to our recognition of the wide-spread service he had rendered to the medical profession in all its branches. After speaking on the phenomena of disease, the attendant signs and symptoms, and changes in type of disease, the orator proceeded to dwell more fully on surgical diseases, paying well-merited tributes to Mr. Hilton, a former President of the College, for his philosophical essay on the *Influence of Physiological and Mechanical Rest in the Treatment of Surgical Diseases*, and to ex-Presidents Sir William Fergusson and Mr. Hancock for their work in conservative surgery in saving limbs by excision of the diseased joints, Mr. Clark proceeded to point out that, in Hunter's time, but little was known with exactness either as regards the functions, the minute structure, or the morbid changes in organs or tissues; but organic chemistry, the microscope, and carefully conducted experiments, had placed within reach a vast amount of ascertained facts, to which our therapeutic mastery over disease bore but a modest proportion. Indeed, it was since Hunter exemplified the close alliance between these sister sciences, and their true relation to practical medicine, that some of our most distinguished surgeons had gained their legitimate laurels by their joint cultivation.

A more conspicuous illustration of this was afforded by the teaching and published writings of Sir James Paget, the senior Vice-President of the College.

Mr. Clark afterwards discussed a subject which had occupied much of the attention of the medical corporations throughout the United Kingdom—viz., education—adding that the prejudices and the obstacles to the diffusion of practical knowledge which Hunter had to combat were not yet extinct, and that teaching was not entirely blameless in the matter. He freely and thankfully admitted the beneficent change which had been wrought of late years in the character of medical teaching generally, and in the moral tone and preliminary education of students. Yet the system of instruction was not perfect; indeed, it might be questioned whether the efforts to make it so had not overreached their mark in the invention of facilities for learning, and to the prejudice of the students' best interests in after-life. It seemed as if the hurried competitive life now being led were uncongenial to reflection. It was impossible for those whose duty it was to test the attainments of students to ignore the fact that knowledge was acquired too often without reflection; that even the more intelligent were sometimes satisfied to store their minds with facts, without seeking for an explanation of them. Mr. Clark was, he said, jealous of the artistic illustrations which were scattered broadcast through anatomical and surgical text-books; for he feared that their abuse too often lured the student into the fatal error of believing that he could thus acquire that which should be learned only in the dissecting-room and by the bedside. What would John Hunter, whose life was spent in intercourse with Nature, have said to this? The prepared College dissections were copied to facilitate their recognition; selected museum-specimens were studied that they might be identified; written questions were stored for the instruction of future candidates for the diploma, as if this were the *Ultima Thule* of their aspirations or responsibilities. Suggestive writing, personal dissection, and even clinical teaching, had not the popularity which was accorded to exhaustive or dictatorial instruction, because the latter saved the learner the trouble of reflecting on what he was taught, of seeking for a meaning in what he witnessed, of pondering on the relation between cause and effect.

Possibly the time allowed for study was not commensurate with the extent and variety of the information now required of candidates for a medical degree; possibly the student preferred that method of learning which cost him the smallest expenditure of time and energy, and yielded the readiest return in his success at his examinations. Whatever the explanation might be, the result too often was a quickened memory, but an otherwise undisciplined intellect; and, as a natural sequence, where such was the case, in the responsibilities of practice, the frail reed of precedent was leaned upon, because the sustaining resource of sound principles had never been properly appreciated, and the learner had not cultivated the habit of thinking for himself. In making this observation, Mr. Clark directed the attention of his audience to the well known and truthful portrait before them (that by Reynolds of Hunter, before alluded to), and asked, "Was meditation a trouble to him it represented? There was no difficulty in crediting the exclamation attributed to Hunter, 'It is a pleasure to me to think'."

In conclusion, Mr. Clark, in speaking of the late Bishop of Winchester, a trustee of the Hunterian Collection, observed that "he was indefatigable with the indefatigability which has been called one of the truest signs of genius". Such words were spoken with equal propriety over the mortal remains of an eminent divine, whose sudden death was a shock that vibrated through the length and breadth of the land; and in this characteristic, evinced and exercised in such different spheres of labour, and with tendencies and acquired tastes in which there were few other points of contact, there was a near resemblance between John Hunter and Samuel Wilberforce. And, in the close of their long day of toil, they were alike; for, "when the night came upon them, it was as with the sun of the tropics; there was no twilight". The interest taken by the late trustee in the museum, and his frequent presence on these commemorative occasions, would justify this passing tribute to the memory of one whose character endeared him to all who knew him, and of whom, as an accomplished Christian gentleman, Englishmen were justly proud.

"Great deeds cannot die;
They, with the sun and moon, renew their light
For ever, blessing those that look on them."

But pre-eminently was John Hunter's life imbued and characterised by a love of Truth. It was the "mystic altar" before which he ever knelt, the energising impulse which determined and regulated his every aim and purpose, the guiding star of his existence; and it is also the most precious legacy he has left to us, who delight to honour him, or desire to emulate his virtues, and to tread, however humbly, in the footprints of his fame.

THE TREATMENT OF HABITUAL DRUNKARDS.

REPORT OF THE COMMITTEE OF THE BIRMINGHAM AND MIDLAND COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

We are requested to publish the following report, to which we invite the attention of the Branches.

Your Committee, appointed in October last "to consider the best means of furthering legislation for the care and restraint of Habitual Drunkards", having held several meetings, and having put themselves into communication with members of Parliament interested in the subject, have come to the conclusion, that the best steps to be taken at the present stage are to present a petition from the profession at large to the House of Commons, and to send a deputation of the British Medical Association to the Home Secretary.

With this end in view, they have drawn up a circular, with the intention that it should be forwarded to the secretaries of all the Branches of the Association.

At the last meeting held by the Committee, the following resolution was moved by Dr. Russell and seconded by Mr. West, and carried unanimously; viz.:

"That the circular drawn up by the Secretary be adopted by this Committee, and presented to the Branch, with a recommendation that it should be printed and forwarded to all the other Branches of the Association."

The circular referred to in the foregoing resolution is as follows.

"Sir,—The Birmingham and Midland Counties Branch of the British Medical Association, at the ordinary meeting held on October 5th, 1874, passed unanimously the following resolution; viz.:

"That a Committee of the Branch be appointed to consider the best means of furthering legislation for the care and restraint of Habitual Drunkards."

"The Committee have since held several meetings, and have come to the conclusion that, at the present stage, the best steps to take for effecting the object in view would be to present a petition to the House of Commons from the medical profession at large, and to bring the question under the notice of the Government by means of a deputation of the British Medical Association to the Home Secretary.

"With this view, they desire to obtain the co-operation of all the Branches of the Association, and request you to have the kindness to bring the matter under the notice of your own Branch at the first possible opportunity.

"They will feel much obliged if you will do this, and communicate the result to them as soon as you can; so that they may be enabled to frame a petition embodying the views of the Branches, and may make such arrangements as may seem desirable for organising a deputation to the Home Secretary. Meanwhile, they propose drawing up a draft petition, to be submitted to the Branches for consideration by publication in the JOURNAL of the Association, or otherwise.

"They beg to state that, in their own view, it is desirable to adopt, as the basis of any future legislative measure, the 'Bill for the Better Management of Habitual Drunkards', brought in by the late Mr. Dalrymple in the House of Commons in 1873, which Bill was itself based upon the report of the Select Committee appointed to inquire into the best plan for the Control and Management of Habitual Drunkards', which sat in 1872, and of which Committee the late Mr. Dalrymple was Chairman.

"For further information, and for details supporting the views held by the Committee, they beg to refer you to the above mentioned report published in a Government Blue-book in 1872, to Mr. Garman's Presidential Address at the last annual meeting of the Birmingham and Midland Counties Branch, published in the JOURNAL of July 25th, 1874, and to a paper read by Dr. Russell before the same Branch, which appeared in the JOURNAL of November 14th, 1874.

"On behalf of the Committee,

"W. C. GARMAN, *Chairman*."

BIRMINGHAM MEDICAL INSTITUTE: ADMISSION OF "HOMOEOPATHS".

[FROM AN OCCASIONAL CORRESPONDENT.]

A MEETING of the Committee appointed, at a general meeting of the profession, to settle the first list of members, was held on Friday last week. The fact, that several homoeopathic practitioners had applied for admission gave great zest to the proceedings. The discussion, though pointed and animated, was conducted with temperance and good feeling. This would scarcely have been the case a few years ago.

The arguments against their admission may be summarised as follows:—That the voice and influence of all our masters and leaders had always been given to discountenance any association, still more any such amalgamation as that proposed; that, as societies were to meet in the institute, they would be entitled to, and might justly claim, the right of joining such societies; that they would want homoeopathic books; that they did not believe what they practised, or practise what they professed to believe; that, had their therapeutical opinions been known to the corporations from which they had obtained their diplomas, those diplomas would not have been granted; that such a recognition would, in the eyes of the public, give a sanction to their principles and practices; that it would deter ordinary practitioners from joining the institute, the utility of which would be thereby impaired; that the honour, dignity, and status of the profession would be seriously damaged.

These arguments were thus combated:—That we are quite capable of forming our own opinion as to what it is right to do in such a matter, and are not to be bound by any such authority as that invoked; that to exclude any qualified member of the profession from a library where no one person is bound to speak or associate with another would be ascribed by laymen to a pure *odium medicum*; that it would be inconsistent with freedom of opinion, the battle for which had already been fought in the streets of Birmingham by Dr. Priestley, under the shadow of whose statue we were assembled; that it would damage and imperil the honour, status, and dignity of the profession, in the eyes of laymen, to perpetuate such exclusiveness; that the societies meeting in the institute would pay rent for the privilege of so meeting, and could, therefore, exercise their own discretion as to whom they would admit or exclude; that the admission of homoeopaths to medical societies, and the propriety of meeting them in consultation, were foreign to the question at issue, and might be dealt with at the proper time and in a proper place; that homoeopaths had relinquished many of their positions, dynamisation was gone, *similia similibus* was admitted by them to be a partial and not an universal principle; that, in fact, as a body, they were disintegrating, and were kept together to a very large extent by the quasi-persecution to which they had been subjected; that their ostracism kept alive a feeling of sympathy with them; that it was really, therefore, politic on the part of those who disliked them to absorb them, and so hasten that process of dissolution which had already set in; that it was ignoble on the part of so powerful a majority as we are to continue to punish a feeble minority by cold-shoulderism and contumely, the endurance of which was strong evidence of the genuineness of their faith, as was also their relinquishment of those dogmata which they had found reason to consider untenable; that, in a complete library, as we hoped ours would be, we must have heterodox as well as orthodox books, or submit to the imputation of condemning that which we had not taken the trouble to understand.

Sixteen voted for the admission of the homoeopaths, and six against it. Two, I believe, remained neutral. Of the country practitioners, I think I am right in saying that but one voted in the minority.

ASSOCIATION INTELLIGENCE.

SOUTHERN BRANCH: SOUTH HANTS DISTRICT.

THE next ordinary meeting of this District will be held on Tuesday, February 23rd, at 8 P.M., at the School of Science and Art, Portsmouth: W. H. GARRINGTON, Esq., J.P., will preside.

Notice has been received of the following communications.

1. Dr. W. H. Axford: On Dysmenorrhoea.

2. A Case of Resection of Knee-Joint; etc.

J. WARD COUSINS, *Hon. Sec.*

STAFFORDSHIRE BRANCH.

AN ordinary meeting of this Branch will be held at the London and North Western Hotel, Stafford, on Thursday, February 25th, at 6 P.M.

VINCENT JACKSON, } *Honorary Secretaries.*
RALPH GOODALL, }

February 16th, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: PATHOLOGICAL AND CLINICAL SECTION.

AN ordinary meeting of the above Section will be held at the Midland Institute, on Friday, February 20th, at 3 P.M.

VINCENT JACKSON, } *Honorary Secretaries.*
ROBERT JOLLY, }

Birmingham, February 16th, 1875.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 12TH, 1875.

SIR WILLIAM JENNER, Bart., K.C.B., M.D., F.R.S., President,
in the Chair.

President's Address.—There was a very large attendance of members and visitors, who listened with marked attention and frequent applause to the inaugural address of the President, which is published at page 233.

Dr. GREENHOW said: The proposition that I have to submit to you is one that you will most cordially accept. Our President, at the commencement of his address this evening, said he had felt some misgivings, on accepting the presidency, as to his ability to give us an inaugural address. I need not say to you, gentleman, that his misgivings were entirely unfounded, for we have heard this evening a most admirable address. This Society has been fortunate, so far, in having as its President always some gentleman in the very forefront of medical science and medical position. We have had in succession the very ablest men that could be selected to fill the office. I have myself sometimes felt misgivings as to whether it was wise to go on inviting our President from year to year to give an inaugural address. We all know how difficult it must be for gentlemen to go on addressing us on the self-same topic. We can all feel how difficult it must be to deliver a Harveian or Hunterian Oration; but it so happens that our Presidents have all been men possessed of a peculiar idiosyncrasy, which they have impressed upon their addresses. Whilst it would be far from me to say that one address was better than another, I venture to say that from the day when Sir Thomas Watson gave the first address at the opening meeting of this Society to this evening, our addresses have all been of first-rate quality, such as to reflect honour on those who gave them and honour on the Society to which they were delivered. It would be presumptuous in me to say more on this subject; I therefore merely beg to propose that the cordial thanks of the Society be given to the President, and that he be requested to hand his address to the secretary for publication in the next volume of the *Transactions* of the Society.

Mr. BARWELL seconded the motion, which was unanimously agreed to.

Paralysis of the Serratus Magnus Muscle.—Dr. POORE exhibited a patient with this disease. The man, aged 43, stained his right arm on the 19th of May, 1874. He suffered greatly from pain and other symptoms indicating neuritis of the brachial plexus, but the pain was quickly removed by the use of the galvanic current, combined with the rhythmical exercise of the muscles of the arm. On August 20th, three weeks after the disappearance of the pain, and three months after the injury, paralysis of the right serratus magnus came on, and still remained. The phenomena presented were the following. With the arms at rest by the side, there was nothing obviously amiss, except that the inferior angle of the right scapula approached the middle line somewhat more closely than that of the left; when, however, the serrati were brought into action by holding the arms forward, the spinal border of the right scapula started away from the chest-wall like a wing, and the upper end of the spinal border was drawn slightly upwards and inwards; there was no difference in the level of the shoulders, and no difficulty in raising the arm above the shoulder; the digitations of the serratus were visible on the sound, but not on the paralysed side. By means of diagrammatic sections of the thorax taken with the leaden cyrtometer, Dr. Poore was enabled to show the effect of this paralysis on the thoracic wall. When the serrati were not in action, the sections were nearly bilaterally symmetrical; when, however, the left serratus was brought into play, the section showed that on the healthy side there was lateral bulging of the thorax, due to the pulling upwards of the ribs by the serratus magnus, while on the paralysed side there was no such bulging, but the projection backwards of the scapula was strongly marked. During deep inspiration, the want of symmetry became still more strongly marked. The phenomena presented by the patient differed from the description given by Duchenne, since there was no depression of the shoulder and no tilting upwards of the inferior angle of the scapula when the hands were held forward. The phenomena were at variance also with Niemeyer's description, since that physician stated that paralysis of the serratus magnus rendered the raising of the arm above the level of the shoulder impossible. The cause of the paralysis was doubtful. Had neuritis of the median or musculo-spiral nerve crept slowly up the limb and fallen with undue severity on the nerve supplying the serratus? Dr. Poore thought not, because, early in the history of the case, the patient had complained of

pain when the serratus was put in action, although there was no paralysis, a fact which would indicate that the posterior thoracic nerve was implicated. It was possible that the paralysis had been the price, as it were, paid by the patient for his relief from pain. The removal of the pain had enabled him to use his arm, and possibly the movement when rest was indicated had changed his pain into paralysis. Dr. Poore was not aware that the effect of this paralysis on the chest wall, though obvious enough, had been previously demonstrated.

Lepra Anæsthetica.—Dr. SOUTHEY exhibited a patient who was suffering from this disease. The patient, a male, aged 25, had been under Dr. Southey's care at St. Bartholomew's Hospital. He was of a fairly healthy complexion, and in a state of moderately good muscular nutrition. His most characteristic peculiarity was in his hands, which were cold and wasted looking, with shrivelled wrinkled skin; and the peculiar bird's talon-like position assumed by the fingers, and the incurvature of the back of the hand when he opened it, at once attracted attention, and served as a means of diagnosis. The skin and tissues of both his hands and feet were affected, and this affection was due, not merely to absorption or diminution of the ordinary subcutaneous fat, but to generally impaired nutrition. The tactile sense had almost altogether disappeared, and the organs by which it was carried on had especially suffered; thus the skin at the finger tips and on the palmar surface was nearly quite smooth, the concentric rows of papillæ being scarcely discernible. Here and there upon the fingers were scars of old burns and injuries, produced by his holding mugs, cups, and plates, which were too hot, and which blistered him without his being conscious of the fact. On the plantar surface of his right foot was an ulcer, now looking nearly healed, which he stated was the result merely of an injury from his boot, and, though not exactly in the ordinary spedasked ulcer site, appeared ominous both by situation and appearance. The history of the case appeared to confirm the diagnosis. He was born of English parents, and had resided, up to November 1873, in the hill country of Southern India, upon a cinchona and coffee plantation. In 1869, he had contracted some venereal affection, which was followed by a severe crop of boils and by two whitlows upon his fingers. Soon after this, he noticed some impairment of sensation, first in one finger, which gradually extended over both hands. At or about the same time, a large patch of discoloration of the skin, occupying an area of some twelve or fourteen inches, about the right knee, made its appearance; it was of a dusky red colour, felt a little thicker than the rest of the skin, and itched slightly. Loss of sensation in the patch soon became apparent to him, so that he could prick or scratch it without evoking the slightest pain. Subsequently, several similar patches showed themselves in different parts of his body, the most recent having involved his right ear; this organ, however, was certainly not anæsthetic, but he stated that it was so some seven months ago, when he left India, and that it had recovered sensation since his sojourn in England. Fourteen months ago, he had first noticed wasting of the muscles and deformity of the hands, and this had been accompanied by dull, heavy, aching, and occasional dragging pains in his fingers and up the forearm to behind the elbows. The patient had been treated with mercury (though never to salivation), arsenic, liquor potassæ, and iodide of potassium, but without deriving much benefit. His change of habitat, however, to this country had been attended with some amelioration. It was interesting to note that he had lived all his life in the hill district in India; that both his parents were born and lived in India; and that his grandfather was the original settler or migrator from this country. Thus two generations of acclimatisation had in this instance sufficed to confer such an altered habit or idiosyncrasy upon an European body, as to enable it to acquire a specially indigenous disease.

Dr. BUZZARD proposed that, as the usual time of the meeting had expired, the discussion on both the above papers should be deferred until the next meeting of the Society. This proposition was adopted, and the meeting terminated.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, FEBRUARY 2ND, 1875.

GEORGE D. POLLOCK, F.R.C.S., President, in the Chair.

Aneurism of the Heart.—The report of the Morbid Growths Committee on Dr. Southey's case of aneurism of the heart was read. They agreed entirely with the description given by Dr. Southey (see p. 61).

Elongation of Bones from Disease.—MR. HOWARD MARSH exhibited a case of elongated bones of the lower extremity in a case of diseased knee (living specimen). The patient was of phthisical family. In August 1869, the left knee became painful and swollen from serofulous inflammation of the synovial membrane. By means of a splint,

Scott's dressing, and cod-liver oil, she improved much, and in the summer of 1870 was nearly well. The condition of general struma was marked, and the knee gradually again grew worse. Small incisions became necessary, and the limb was laid on a back splint. She was three years in bed with it. Three years ago, the limb was first observed to be longer than its fellow. From the abnormal vascularity of the parts, the femur had become one inch and a half longer than that of the sound side. Motion was interfered with.—Mr. WAGSTAFFE said that this was a case of great interest. Nevertheless, the condition was not very rare. In five cases of similar disease of the knee-joint, now in St. Thomas's Hospital, two had elongated limbs, either in the tibia or femur, or both. In one case, the elongation amounted to five-eighths of an inch, in the other to one and a half inches. In one case, the limb was shorter than the sound one. After excision of the knee-joint, the limb was often found less short than had been anticipated, owing to this elongation.—Mr. HORTHOSE thought this morbid change not quite so common as Mr. Wagstaffe suggested, or it would be more commonly met with. Apparent elongation in such cases, by the lowering of the pelvis of the affected side, was far from unusual; but it was a different affair with real elongation.—Mr. HOWARD MARSH asked if any of the Fellows could tell where a case of real elongation was described anywhere in surgical works. Neither in the works of Paget nor Dupuytren could he find an account of this change.—Mr. WAGSTAFFE said the change was not described anywhere. In the cases he mentioned, the elongation was actual, not apparent. In the case of shortening, the tibia was defective.—The PRESIDENT observed that these cases were very rare; he had only seen two.—Mr. DE MORGAN had not seen many such cases. At present, he could only remember two, and could not say whether the elongation was in the femur or in the tibia.—Mr. HULKE said such cases were, in his opinion, neither so rare as Mr. Marsh supposed, nor so frequent as Mr. Wagstaffe would infer. In a case of a child thirteen years of age, which came under his notice, there was great overgrowth of one lower limb; this, however, was not from joint-disease, but from teleangiectasis. He had also noticed a curious form of disease where one bone of a limb outgrew its fellow. In three cases, he had seen the radius so outgrow the ulna that it became quite arched. In these cases, there was no chronic disease nor afflux of blood.

Leprosy.—Dr. PYE-SMITH showed a case of leprosy. The boy was sixteen years of age, born in India. His father was a Scotchman and his mother a half-caste. There were spots of anaesthesia on the arm. The disease affected the palate and larynx. On laryngoscopic examination, the left vocal cord showed one or two nodules.

Tumour of the Arm.—Mr. DE MORGAN exhibited a case of tumour of the arm, the nature of which was not quite clear. It was evidently connected with the nerves. It occurred in a young lady aged fourteen, quite healthy, and of a healthy family. The tumour was of some years' standing. There were several tubercles under the hypertrophied skin, which formed bead-like bodies. There was also a general fullness of the arm. The growth was not in connection with the muscles. There was good movement of the arm, and the owner could play the piano freely. The limb perspired profusely. There was some irregularity observed in the limb at birth, and the swelling gradually increased, and became painful on pressure. The skin was movable over the tumour. There was pain felt over the thumb. In January last, the swelling had increased, and the bead-like surface was more pronounced. Movement was diminished; an operation was therefore decided upon. The radius had become eroded and had given way. There was found a cyst full of dark tenacious fluid. The musculo-spinal nerve was as thick as a finger. The muscles were expanded over the tumour. The nature of the tumour was doubtful, but it appeared to be connected with the nervous system, and was possibly some form of neuroma. At first, he had been inclined to think it might be a form of lymphatic growth.

Sarcomatous Tumour of the Eye.—Mr. GEO. LAWSON exhibited an eye which he had removed on account of a sarcomatous tumour, which grew from the sclerotic and cornea. The tumour first appeared as a small black speck on the conjunctiva at the inner side of the eye, two years previously. It continued to grow, until August last, when it had attained such a size that the patient was unable to close the lids over it. Up to this time, he had refused to submit to any operation, but he then permitted Mr. Gooch of Windsor, under whose care he was, to excise it. The tumour, however, immediately reappeared, and continued to increase, until early in November, when Mr. Lawson first saw him. There was then a large warty excrescence springing from the sclerotic and adjacent cornea on the inner side of the eye, overlapping the cornea, so as to cover the greater portion of the pupil. It was very painful, and repeated hemorrhages took place from the surface, so that the patient was becoming exhausted from the frequent small losses of blood and the pain. Mr. Lawson excised the eye; and, on making a section of it, the growth was found to be a round-celled sarcoma, confined to the sclerotic

and cornea, and not involving the iris or ciliary processes. The patient made a good recovery, and there had been no recurrence of the disease.

Melanoid Sarcoma in a Cod-fish.—Dr. HOGGAN exhibited microscopical specimens of melanoid sarcoma in a cod-fish. The tumour was black and nodulated. Under the microscope, it was found to consist of round and oval pigment-cells, amidst fibrous trabeculae.

Sarcomatous Growth of Omentum.—Mr. KNOWSLEY THORNTON related the case of a female, aged thirty, who first suffered from abdominal troubles during her first year of married life. Then there was fluid in the peritoneum. She was tapped, and eleven pints of greenish ovarian-like fluid came away. The patient died. On microscopical examination of a growth seated on the omentum, it was found to be a form of sarcoma, fibre-celled chiefly, though round cells were numerous. One ovary was infiltrated with a similar growth, and there was a nodule of it in the liver. The diagnosis in life was exceedingly obscure and difficult.

General Sarcoma.—Dr. HOGGAN showed microscopical specimens from a case of general sarcoma. The different organs in the abdomen were greatly affected. Under the microscope, the lining membrane of the uterus was found to be disorganised. There was a cancerous mass in the pylorus.—Dr. COUPLAND said that it had been announced that the specimens exhibited were put up after a new process. He asked what it was.—Dr. HOGGAN replied that the process was invented by a lady, and that it would not be fair to divulge it.—Mr. HULKE said that it might be as well if Dr. Hoggan had an opportunity afforded him to describe the method adopted. He could scarcely imagine that any member of that Society would purpose to describe a method and then decline to do so.—Dr. HOGGAN replied that if the lady, who possessed a medical degree, were made a member of the Society, doubtless she would explain her process. Not to possess her process was a loss to science.—The PRESIDENT thought the matter hardly a subject for discussion.

Incomplete Direct Inguinal Hernia.—Dr. DOWSE exhibited an incarcerated portion of bowel in the inguinal canal, which formed an incomplete direct inguinal hernia. The subject of it was an old woman aged 79. The bowel where constricted had become sphacelated, and by progressive ulceration an artificial anus resulted. A month previous to the patient's admission into the Central London Sick Asylum, she was seized with obstinate vomiting and constipation, which continued for a fortnight. After this, the bowels were relieved, but a hard and painful swelling showed itself in the right groin. When Dr. Dowse first saw her, there was neither vomiting nor constipation of the bowels; but upon examining the abdomen there was diffuse cellulitis of the right abdominal wall, with great hardening about Poupart's ligament; and over the internal abdominal ring, midway between the antero-superior spinous process of the ilium and spine of the pubes was a large bleb, which soon ruptured, and the aperture gave exit to fecal matter. The patient sank from an exhaustive attack of diarrhoea. At the post mortem examination, all the parts in the abdomen were healthy, but the lower free border of the ileum was found invaginated in the inguinal canal, and adherent to the internal abdominal ring. There was free communication between the bowel and the skin.—Mr. WAGSTAFFE asked if by an invaginated intestine an intussusception were meant.—The PRESIDENT asked if there had been no vomiting.—Dr. DOWSE replied that there had been vomiting before the case came under his care. There had also been constipation. It was not an intussusception.—Mr. H. MORRIS asked if it were not an incarcerated hernia, running on into intussusception.—The PRESIDENT thought a portion of intestine might have dragged away and dilated, or it might have been an imperfect diverticulum.—Dr. GREENFIELD inquired if one side was partially nipped. The answer was in the affirmative.—Dr. H. GREEN said that, when fresh, it appeared like a diverticulum.

Syphilitic Ulceration of the Rectum.—Dr. DOWSE showed two specimens of syphilitic ulceration of the rectum. The first was taken from a patient aged 37, who was admitted into the Central London Sick Asylum in July 1874, and died the following December. When Dr. Dowse first saw her, she was suffering from well marked tertiary syphilitic sores and cicatrices. There was extensive ulceration around the labia of the vagina, and mucoid elevations around the anus. About twelve months previously, she complained of pain when passing a motion, which was usually attended with hemorrhage. The bowels soon began to act very irregularly; sometimes there was persistent diarrhoea, with blood and pus, at other times there was distressing constipation, with colicky pains and tormina. Around the anal aperture, were to be seen the cicatrices of old fistulae. There was a stricture of the bowel just beyond the internal sphincter, which would admit the forefinger. The ulceration commenced at the verge of the anus, and was continuous up the gut, the wall of which felt rough and uneven, like a worn-out nutmeg-grater. At the necropsy, the rectum, when slit up, was found to be diseased throughout its entire course. It presented an irregular surface of a greyish green colour, with here and there somewhat pendulous-looking

masses of almost vermilion redness. The second specimen was taken from a patient aged 27, who for the second time was admitted into the Central London Sick Asylum in September 1874, and died in the following December. The history of the case was similar in most respects to that just narrated. There were, first, acute pain upon defecation; second, irregular action of the bowels, with hæmorrhage and severe colicky pains with tormina. The hæmorrhage was succeeded by the discharge of a dark-coloured fluid of blood and pus. This patient died from lung-disease, albuminuria, waxy liver, and kidneys. The state of the rectum was in most parts as that just shown. Dr. Dowse remarked that in his experience relative to syphilitic disease of the rectum, one did not, as a rule, find chronic periosteal disease with caries and necrosis of bone, but rather a determination to the skin, connective-tissue, and mucous membranes. Hæmorrhage from the air-passages and albuminuria were associations by no means uncommon, as were also psoriasis of the tongue, hands, and feet, condylomated thickening about the anus, and diffuse cicatrizations of the skin from previous ulcerations.

Enlarged Liver and Spleen.—Dr. PYE-SMITH exhibited an enlarged liver and spleen without leukemia. The patient was a cabman aged 46, who came into Guy's Hospital in November last. There was a history of syphilis. The veins of the face were enlarged, as if there also existed intemperate habits. There were purpuric patches on one leg. The spleen and liver were much enlarged. Double pleuritic effusion came on. The diagnosis was cirrhosis of liver, with fatty deposit and granular kidneys. There was no albuminuria. The man died with nervous symptoms, low delirium, and albuminuria. The temperature was rather below the normal than above it. The *post mortem* examination only made the case more unintelligible. The kidneys were diseased in their structure (microscopically), and the surface was granular. The heart presented evidence of old pericarditis, and altogether weighed eighteen ounces. The valves were healthy. The liver and spleen were smooth. The liver weighed eighty-eight ounces and the spleen eighty-three ounces. It was the spleen of leukemia. Nevertheless, under the microscope the blood was seen to be perfectly healthy. The absence of blood-change made the diagnosis difficult.

Hæmorrhage in the Joints in Gout.—Dr. PYE-SMITH showed a specimen of hæmorrhage into the joints in a case of gout. The man died six weeks ago. There were no peculiarities in life, and no albuminuria. It was a case of gout; the man had been ill several weeks, and had been ailing for four years. When he came into hospital, he had a bed-sore which had healed. There were no sudden symptoms. Urates of soda was found in all the joints; there was interstitial nephritis. In all the joints there was extravasated blood. A cupful (shown) came from a knee-joint. Many joints were equally full of blood. Such a case was rare. The patient had not had purpura.—Dr. HILTON FAGGE related a somewhat similar case, where there was extreme congestion of the knee-joints in a case of dropsy with bronchitis. The man had tophi in his ears. There was gout in the great toe. There was also pus in the forefinger. In the knees there was urate of soda, with much synovial fluid. There was no complaint made of the knees in life. Suppuration in the joints was rare in gout.

Cancer of the Breast and Liver.—Dr. PEARSON showed a case of cancer of the breast and of the liver from a female aged 64. The interesting part of the case was the skill with which the sufferer had concealed her open cancer of the breast from her friends and her medical man. It was only discovered after death.

TUESDAY, FEBRUARY 16TH, 1875.

GEORGE D. POLLOCK, F.R.C.S., President, in the Chair.

Inguinated Intestine.—The Report of the Morbid Growths Committee upon Dr. DOWSE's case of inguinated intestine was read. There was a diverticulum of the intestine caught in a direct inguinal hernia, in which a fecal fistula had formed from ulceration.

Ovarian Tumour.—The Report on Dr. MURRAY's Ovarian Tumour was read (see p. 61). It was a lobulated tumour, of the size of a man's head, consisting of several cysts, one considerably larger than the others. There was no clear fluid in any cyst, but a soft kind of new growth. The cysts were scarcely true cysts. In the more recent parts, the new growth was cellular, the cells being round, oval, or irregular in shape, so that it resembled in character the tissue of sarcoma. In the old portion, the cells were smaller and finer, and the stroma was hardened. The cells resembled leucocytes, and were about a third of a lymph-corpuscle in diameter.

Congenital Defect of Clavicles.—Dr. DOWSE exhibited a case of congenital defect of the clavicles (living specimen). The girl, aged 17, was the eldest of eleven children, all of whom were perfectly healthy. During the intrauterine existence of this girl, her mother went into the country for the first time in her life, and was much alarmed at a large number of frogs there existing. She stepped upon these frogs from time

to time, which increased her alarm. The child was born at the full time, and at birth some deformity was observed. It also performed frog-like movements. Such was the story of the child's grandmother. The child went through the troubles of infancy quite smoothly; at nine, it commenced to have epileptic fits. One point Dr. Dowse wished to point out strongly was, that this child could do all that perfectly developed persons could do—and more. The child could bring the shoulders together over the chest.—Mr. WAGSTAFFE inquired if there were any bone at the outer end of what should have been the clavicle, or if there was a joint in the clavicle. He should also like to know at what time during pregnancy this fright was received, as the clavicle was a bone that ossified early.—Dr. DOWSE replied that there was no central joint, and no true acromion process. The fright occurred during the third month of pregnancy.—The PRESIDENT suggested that some of the surgeons in the room should examine the child. This was accordingly done; and, after some other communications had been made to the Society, Mr. HENRY SMITH said it was a difficult task, and it was very fortunate that they were not being examined before the Lord Chief Justice, as it might not have been easy to agree. There was, doubtless, bilateral distortion, and spaces on each side where the clavicles finish. What were the bones at the acromial end? Were there intrauterine fractures, and not an arrest of development? Disagreement was very easy.—Mr. MORANT BAKER thought that Dr. Dowse was right, that there was arrest of development. The coracoid process could be felt, but not the acromion process. The patient could bring the shoulders together in front, and that went against Mr. Smith's view. For his part, he was glad that they were not being examined before the Royal College of Surgeons.—Mr. CAMPBELL DE MORGAN agreed with Mr. Smith. He thought he could feel the acromion process on the left side, and possibly also on the right side. This case furnished a new view of clavicles: the patient had more power than those who possessed clavicles—could do all that others could do, and more. Were clavicles useless vestigia?—Dr. PYE-SMITH supported Mr. Baker's view. On the right side the fibres of the coraco-brachialis could be felt to be attached to the bone, whatever it was, and from that he thought it hardly likely to be an acromion process. There was an arrest of development resembling what is found in the carnivora. The external ends of the clavicles were not developed.

Double Thoracic Aneurism.—Dr. BURNEY YEO read an account of a double thoracic aneurism. The patient died in King's College Hospital last week. There were two aneurisms. One was easily recognisable in life, the other was only suspected. The suspected one was the cause of death. The first was in the ascending aorta, and was of the size of a hen's egg; it communicated with the aorta by a large opening. Its walls consisted of several layers of fibrin, and it was adherent to the cartilages of the second and third ribs. The aortic arch was normal. There was an aneurism in the descending aorta, of a dissecting character. The posterior wall of this aneurism consisted of the bodies of the fourth, fifth, sixth, and seventh dorsal vertebrae, which were much eroded. There was an ulcer at the point of contact with the oesophagus, and a hole of the size of a sixpence. There was no general inflammatory adhesion betwixt the aneurism and the oesophagus. The aneurism fell away from the oesophagus on the parts being lifted. There was much atheroma in the aorta. The valves and walls of the heart were quite healthy. The stomach was full of blood-clots. The symptoms in life were pain in the right side, cough, and dyspnoea. The man stooped forwards, for when he stood straight up there was pain, and stridulous cough induced. He was thirty-eight years of age, unmarried, and had had syphilis. He had had a fall some months ago, and had had much cough since Christmas last, when he had a bad cold. The chest was emphysematous; there were dulness and pulsation at the ascending aorta, and a systolic murmur at the base of the heart. The pupils were equal. After fourteen days' rest in bed, he was much easier. On the 2nd of the month, he could swallow food without difficulty; on the 9th, he wished to go out of hospital. On the 11th, he sat up in bed and had some food, when he felt faint, and blood came up freely without cough. In the afternoon the hæmorrhage returned, and was fatal. The opening into the gullet was sharply cut, and had a punched-out appearance. There was no dysphagia, except occasionally, and then it was only slight.—Dr. THEODORE WILLIAMS had seen many aneurisms, but only one case of double aneurism in the same arterial trunk. The second aneurism might easily be overlooked. If the patient had lived, doubtless the second aneurism would have pointed. He thought the case a very interesting one.

Fatty Degeneration of Muscles.—Mr. CRIPPS brought forward a case of fatty degeneration of the muscles of the thigh, from a body which came into the dissecting-room at St. Bartholomew's. All the muscles of the leg and some of those of the thigh were affected. The fatty degeneration extended from below upwards in the muscles. The muscles

affected were those supplied by the great sciatic nerve. The short head of the biceps, however, was unaffected. The opposite limb was affected in a precisely similar way. The limbs had been too much cut about to permit of a careful search being instituted as to the possibility of some abnormal nerve-supply to the short head of the biceps. The old woman had had paralysis for some time. The sciatic nerve was not affected.—The PRESIDENT thought a report of the state of the nervé desirable. He had seen a similar change in a horse, where the nerve was caught and pressed by the aorta.—Mr. WAGSTAFFE thought a microscopic section of the muscles desirable. Fatty degeneration in voluntary muscles was rare. Fatty infiltration after fracture was common.—Mr. CRIPPS replied that by fatty degeneration in this case he meant that there was no trace of muscular fibrille to be found.—Mr. MORRIS disagreed with Mr. Wagstaffe's remarks as to the rarity of true fatty degeneration in the voluntary muscles.

Contraction of the Coronary Arteries.—Dr. GREENFIELD showed a specimen of contraction of the coronary arteries. At the commencement of the aorta, there was a band of atheroma, by which the orifices of the coronary arteries were much obstructed. On section, the aortic wall was found to be much thickened. The patient, a female, aged 27, was brought into hospital dead. She had felt queer and sick, and died on the way, being ill altogether about half an hour. There was no distinct history of syphilis. The heart was healthy, and the left ventricle contracted. There was no microscopic examination made when the parts were fresh. The muscle was of good colour, and there was but slight fatty change. The interest of the case lay in the youthfulness of the patient, and the absence of symptoms. There was no other disease of the vascular system. Was there syphilis? He was not certain about it.—Dr. HILTON FAGGE inquired if local patches of disease were associated with obstruction of the coronary arteries. He had had no personal experience of such cases. Did muscular changes necessarily follow obstruction of the coronary vessels?—Dr. GREENFIELD replied that we could not assert that almost complete obstruction of the coronary arteries was necessarily followed by fatty degeneration of the muscular structure of the heart. In old persons, these changes were commonly found together. When an arterial trunk was cut in two, molecular necrosis of the parts supplied followed. There were cases on record where, when one coronary vessel was diseased or obstructed, fatty degeneration of the part supplied by it followed. Mr. MORRIS inquired, if one coronary vessel was obstructed, why the parts were not nourished by the anastomoses of the terminal branches of the coronary arteries. Hyrtl said that such anastomoses did not exist, but that day he had seen a case to the contrary.

Obstruction of the Renal Arteries.—Dr. GREENFIELD showed two cases of obstruction in the renal arteries, due to atheroma. The first was from a man, aged 49, who had been in hospital for some time with slight albuminuria and slight jaundice. There was a systolic murmur over the heart. The aorta was rigid and roughened, and there were plates of atheroma. The right renal artery was much diseased, and the right kidney weighed only one ounce and a half. The vessels of the kidney were thickened; the capsule came away easily, and the surface was very granular. The left kidney weighed ten ounces and a half; it was smooth; one lobe was atrophied from atheroma of the artery supplying it. The second case was that of a female, who had an ovarian tumour. There were no symptoms, no albuminuria, but great ascites. The left kidney weighed four ounces and a half; its artery was obstructed. The right weighed three ounces and a half, and was slightly granular, of a yellowish white colour, and the pyramids had white rings in them like sections of vessels. There was a coagulum in the obstructed artery, extending into the aorta. In the right kidney there was some wasting of the cortex, and acute changes in the epithelium like those found in fatty kidney. These cases showed the effects of complete and of incomplete obstruction. One kidney was atrophied, and the other enlarged. When there was thrombosis, there were acute necrotic changes.

Fibroid Disease of Heart.—Dr. GREENFIELD exhibited a case of fibroid disease of the heart, from a man, aged 43, who died suddenly, after being a few hours in hospital. The symptoms were those of advanced heart-disease, with albuminuria and dropsy. The interest of the case lay in a roughened patch on the posterior wall of the left ventricle, to which was attached a honeycomb clot. This was a rare cause of death. There were numerous emboli in the renal arteries, which were indeed stuffed with them. Was death due to the changes in the heart, or to those in the kidneys?

Fatty Tumour in Groin.—Mr. BUTLIN showed a fatty tumour removed in the course of herniotomy. It came from a woman, who was admitted into the West London Hospital in September last, with a hernia. There was a history of hernia for some years, always so far easily reducible. She was forty years of age. There was a large

tumour in the left inguinal region, and much pain. The tumour was quite irreducible, and gave no impulse of cough. In operating, he cleared the sac, but failed to obtain reduction. He then opened the sac, and found the tumour. It at that time was smooth and dark, like a piece of congested lung, and light on the outskirts. A pedicle sprang from it, which was attached to the interior of the abdomen. He cut this, and removed the tumour. The microscopic examination showed that it was a fatty tumour, containing a rather large amount of fibrous tissue. The dark colour was due to blood effused into the tumour in the attempts at taxis.—Mr. WAGSTAFFE asked if it was not a low form of connective tissue tumour.—Mr. BUTLIN replied that at first he thought it might possibly be a diseased ovary, but he had found that it was an enlarged appendix epiploica.

CORRESPONDENCE.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

SIR,—By direction of the College, I send you the following copy of a resolution which they adopted unanimously at their meeting yesterday.

Resolved—That, if the Charter be granted, giving the College the power of instituting an order of members, it is the opinion of the College that any licentiate admitted before the granting of the Charter, who may desire it, may be transferred to the order of members without additional expense. I am, sir, yours faithfully,

Dublin, February 13th, 1875.

J. M. FINNY, M.D.

SIR,—The Licentiates of the King and Queen's College of Physicians are much indebted to you for bringing prominently forward the principal features of the Supplemental Charter which is sought for by the President and Fellows of that College; and I shall feel obliged by your giving me space to point out some of the reasons why this Charter, or some modified form of it, is essentially necessary to the well-being, nay, even to the existence, of the College.

There are but two points really involved in the Charter; viz., that of membership, and the power to elect Fellows and Officers by ballot. As to the former, so long ago as 1867, a Committee of the College recommended that an order of "members" be instituted. The Committee was influenced, in coming to this resolution, mainly by the fact, that very many public appointments in England and Scotland were open only to "Fellows or Members of a College of Physicians"; and, there being no such grade as that of "member" in the Irish College, its licentiates were necessarily excluded from such, and, therefore, occupied a disadvantageous position. It is indeed difficult to understand on what grounds the five dissentients oppose this step, evidently necessary for the well-being of the licentiates. This is more remarkable, as no fewer than three out of the five dissentients signed the report recommending the institution of the order of member.

Since the publication of your article, letters have been received by the Registrar of the College from licentiates resident in various parts of the kingdom, in favour of the proposed order of member; and it is desirable that such as feel interested in the question should express their opinion on the point. The College has always contended that its licentiates should be considered on a par with the members of the sister colleges, inasmuch as they are prohibited from selling medicines, and have to pass a very stringent examination. Consequently, the Committee recommended that, in the event of the power of instituting members being obtained, all persons admitted licentiates prior to the institution of the grade, who had not forfeited their title to it by the commission of some improper act, should be admitted members; this was a mere act of justice to the existing licentiates, and will, doubtless, be acted on.

The question of the Ballot is more open to discussion; but, if the Ballot be necessary for the protection of voters where thousands poll, is it not still more necessary where a comparatively few are called on to decide whether an individual having probably an extensive connection is worthy the honour of the Fellowship? And, as the Colleges of Physicians of London and Edinburgh elect to their Fellowships by ballot, the Irish College claims the same privilege.

The Irish College of Physicians is peculiarly circumstanced. Its Fellowship previously to the year 1861 was restricted to graduates of the Universities of Oxford, Cambridge, or Dublin, and a very stringent limitation this proved. In 1861, the College, at its own request, obtained the power of electing others to the Fellowship, under such limitations as to the President and Fellows seemed fit. Those "limitations"

have never been defined, but their very vagueness could, and, in my opinion, should, be used by the College to extend its basis, and elect out of its numerous licentiates a considerable number of Fellows.

But this desirable course is prevented by the action of the five dissentients, who, by siding with some others who openly admit their wish to limit the Fellowship, have prevented what otherwise would have been the majority from taking the steps necessary to effect this reform.

In the Irish College of Physicians, there is no Council. The Fellowships having been hitherto restricted in number, the Fellows at large exercised the functions of an Executive Council, such as exists in the sister colleges.

The five dissentients who oppose the Ballot also oppose the formation of an Elective Council.

I ask you, sir, would it be possible for a corporate body, consisting of some two or three hundred Fellows, to discharge its functions without the intervention of a Council? The Charter Memorial Committee, of which I was a member, recommended that powers to form an Elective Council should be sought for by the College. This was opposed by the dissentients, they being the leaders of the opposition; yet these gentlemen now declare that we, who urged the adoption of the only course which rendered a considerable extension of the College possible, are narrow-minded, influenced by religious animosity and by a desire for personal aggrandisement.

As it is, the College is too large for the efficient transaction of business; already its meetings are turned to account for the purpose of delivering carefully prepared speeches. A few weeks ago, a Fellow read a speech, which occupied in the reading over half an hour, and which next morning appeared in one of the daily papers. At a more recent meeting, another gentleman, also one of the dissentients, made a speech which occupied forty-five minutes in delivery; the motion in favour of which he spoke was, *inter alia*, for the admission of reporters to the meetings of the College; and, though introduced by so long a speech, it fell to the ground for lack of a seconder. Imagine nearly an hour wasted on the introduction of a motion which no one would second; but, nevertheless, an allusion to this motion was given a prominent place in one of the morning newspapers. I am aware that, in making these statements, I leave myself open to the charge of holding up the College, or at least some of its Fellows, to ridicule; and I regret being obliged to mention these facts; but it is necessary to do so, in order to show that the proposed new Charter, or, what I would much prefer, a modification of it, assimilating the Irish College of Physicians to those of London and Edinburgh, in both of which a Council exists, is essential to the well-being, nay, the very existence, of the College.

I am, etc., LOMBE ATTHILL.

11, Upper Merrion Street, Dublin, Feb. 14th, 1875.

DIPSOMANIA.

SIR,—In my letter on Dipsomania, in the JOURNAL for February 6th, I find that the name of Dr. Harrington Tuke is omitted from the list of those distinguished friends who kindly signed the document referred to in my letter. The omission occurred through an error of my copyist in the first instance, and my own carelessness in not having noticed it before it was sent to press.

I am, etc., CARSTEN HOLTHOUSE.

3, George Street, Hanover Square, February 12th, 1875.

THE CONTAGIOUS DISEASES ACTS.

SIR,—You will perhaps permit me to send one more letter on the influence of the Contagious Diseases Acts, as the statistics given in it seem to me very strong. I am enabled to give them by the kindness of Surgeon-General Mouat, C.B., V.C., and of Surgeons Ambrose and Macnamara, of the 58th and 106th Regiments respectively.

The two regiments named above arrived from India in the early part of 1874, and each brought with it, as usual, a considerable sum of money, which, as usual, passed in large measure into the hands of publicans and harlots before the end of the year. The 58th Regiment went to a station (Portsmouth) under the Acts; the 106th Regiment went to Parkhurst in the Isle of Wight, a much better station than Portsmouth in all sanitary particulars, except that it is not under the Acts.

The 58th Regiment arrived at Portsmouth from India on March 30th, 1874; and, from that date until December 31st, the mean strength was 720 men, and there were admitted 31 cases of primary syphilis, and 37 cases of gonorrhoea. The 106th Regiment went to Parkhurst from India on January 13th; and, from that time to the end of the year, the

mean strength was 561 men; the admissions from primary syphilis were 65; and from gonorrhoea were 61. In each regiment, exactly the same number of recruits (*viz.*, 6) were taken in the year, so that that source of fallacy is avoided. In the 58th, there are 54 men married with leave, and about 12 without leave; in the 106th, there are 70 men married with and without leave.

If we now calculate out what number of admissions there would have been, in the same period of time for each regiment—*viz.*, in a year, and take the mean strength as above, we have the following table:

Regt.	Strength.	Total Admissions per Annum.		Admissions per 1,000 of Strength per Annum.	
		Prim. Syphilis.	Gonorrhoea.	Prim. Syph.	Gonorrhoea.
58th...	720	40.84	48.75	56.72	67.71
106th...	561	67.21	63.66	119.8	112.4

The astonishing difference in the number of admissions in the protected and the unprotected stations is most striking, and must, I should think, impress anybody who is capable of being influenced by figures. But, lest it should be said that the small number of men introduces an error, let us see what the error arising from the small numbers is. In the case of primary syphilitic admissions, the error is in the 58th Regiment $\pm .024382$ to unity, and in the 106th Regiment $\pm .039173$ to unity. In other words, the ratio of admissions per 1,000 might have been in the 58th, the protected regiment, anything between 32.34 to 81.1; and in the 106th, the unprotected regiment, anything between 80.63 to 158.73. So that the highest possible limit in the protected station is nearly identical with the lowest possible limit in the unprotected station. We can only conceive the admissions from syphilis to have been identical in the two stations on the almost impossible supposition that the error arising from the small number was entirely in one direction in one station, and entirely in the other direction in the other station. In gonorrhoea, the range of error lies in the 58th Regiment between 43.29 and 94.19 admissions per 1,000, and in the 106th between 74.69 and 150.13 per 1,000. The case here is almost as strong.

Can, then, any one doubt that the unlucky 106th, by being sent to the unprotected station, has had, in proportion to its strength, more than two cases of syphilis to one case in the fortunate regiment in the protected station? Considering, now, the facts stated in this and in previous letters, and in the army and navy returns, I think I have a right to call on those members of our profession who oppose the Acts to review their position. If they do so, and still oppose the Acts, it can only be, I conceive, on grounds altogether unconnected with statistics. If figures can prove anything, they prove that the Acts have greatly lessened disease; and whoever aids in repealing the Acts, ought to recognise the responsibility thereby resting upon him of increasing, by his action, the amount of venereal disease.

I am, etc., E. A. PARKES, M.D.

Netley, February 11th, 1875.

SIR,—The following facts, derived from a study of the medical history of my late regiment (the 34th), may throw some light upon the vexed question now under discussion, and the utility or otherwise of the above Acts.

We left Shorncliffe, a protected district, in September 1871, embarking at Dover for Ireland, our average strength during the year being 824.41. The head-quarters proceeded to Newry, a half battalion to Enniskillen, and detachments to Kavan, Drogheda, Newtonstewart, Armagh, and Monaghan—all unprotected districts. We lay in these quarters from January 1st, 1872, until July 1st, 1872, when we marched into the Curragh camp, a protected district.

Rate per 1,000 of Admissions.

Disease.	No. of Cases.	Average Duration.	First Six Months, Newry and Detachments; Average.		Second Six Months, Curragh Camp; Average.	
			320.77.	No. of Cases.	272.71.	No. of Cases.
Gonorrhoea.....	48	22.9 days	21	17.86 days	13	28.62
Primary syphilis.....	17	33.32 ..	4	29.25 ..	4	29.25 ..
Secondary syphilis.....	4	32.25 ..	4	29.25 ..	4	29.25 ..

Total, protected districts...69 Protected...38

The average annual strength throughout the year was 871 non-commissioned officers and men.

On referring to my notes, I find that in 12 cases of primary syphilis admitted into hospital at the Curragh, January 1st to May 1st, and shown in the returns as having been admitted in a protected district, 10 were contracted elsewhere, only two at the Curragh (1 at Newbridge, 1 at Kells, 1 at Rath, 1 in London, 1 in Brownstown, none of which places were under the Act). Statistics would show all these as having occurred in a protected district.

In June 1873, the regiment was again divided.

Head-quarters, 380 non-commissioned officers and men, Curragh Camp, protected district; admissions during month, 13.	Left half battalion, Dublin, 374 non-commissioned officers and men, non-protected district; admissions during month, 35.
--	--

Veneral, { Balanitis 1 Gonorrhoea 2 4 { Primary syphilis (soft) ... 2	Veneral, { Bubo 1 Gonorrhoea 11 20 { Primary syphilis 6
---	---

I volunteered for the Gold Coast shortly afterwards, and cannot trace the medical history of the regiment further, but, believe that, upon its concentration in Dublin, the admissions for enthetic disease largely increased. My personal experience of two protected districts, Shorncliffe and the Curragh, was, that the disease was milder in form, more quickly brought under notice, and more easily cured, than in stations not under the Acts; also, that most of the hard or infecting chances were contracted in the latter. The moral tone of the unfortunate women was undoubtedly vastly better in stations under the Acts, and many of them were reclaimed. The statistics which I have quoted favour Dr. Parkes's view of the beneficial effects of the Contagious Diseases Acts, at least as far as the experience derived from the charge of an individual regiment is concerned.

I am, Sir, yours, etc.,

ALBERT A. GORE, M.D.,

Surgeon-Major.

Dublin, February 15th, 1875.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, February 11th, 1875.

Pharmaceutical Society in Ireland.—In reply to Mr. Errington, Sir M. H. BEACH said he hoped to be able to introduce a Bill this session for the establishment of a pharmaceutical society in Ireland.

Consolidation and Amendment of the Sanitary Laws.—Mr. SCLATER-BOTH moved for leave to introduce a Bill for consolidating and amending the Acts relating to Public Health in England, and in doing so he asked the House to favourably receive the measure, which both Houses of Parliament had frequently expressed a desire to see accomplished. The report of the Sanitary Commissioners of 1869 contained a very interesting account of the subject, going back to the reigns of Henry VI and Henry VII, but for practical purposes the consolidation would be confined to legislation since 1848. The Public Health Act of that year was passed under pressure of considerable alarm arising from the approach of cholera. Both previously and subsequently to that date, innumerable local Acts had been passed, but since that time public attention had been more and more directed to this subject, and efforts had been made yearly to improve and facilitate local administration in the country. Many of them had been of a permissive character, and others had contained clauses partly permissive and partly compulsory, but cast upon different models, and they had approached the subject from different points of view, and contained provisions which touched, and in some cases conflicted with each other. The object of this Bill would be to amend and reconcile many of them. Since the Provisional Orders Bill had been in operation, a number of Bills had been passed which contained provisions of law most objectionable to the whole of the community, and the Sanitary Commissioners stated that the number of statutes that had been passed, and the way in which they had been framed, had rendered the state of the sanitary law unusually complex, arising from the progressive and experimental character of modern legislation, without any attempt at reconstruction or classification. The law was frequently unknown, and when studied was difficult to be understood. It was found impossible in passing the Act of 1872 to comprise within it any consolidation of the law, but after two years' experience of its working an amended Act was passed last year of a more uniform character. In fact, it would have been impossible to have worked the Act of 1872 if a digest had not been prepared by the officials of the department. The time had now arrived for making a clean sweep of these Acts; and twenty-nine Acts, passed since 1846, would be more or less dealt with by this Bill, with the exception of five or six clauses contained in them. And the few remaining provisions would be dealt with in future years. It was proposed to consolidate in this Bill the Public Health Acts of 1848, 1850, and 1872; the Sanitary Acts of 1866, 1868, and 1870; the Nuisance Removal Acts; the Local Government Acts from 1858; the Sewage Utilisation Acts; the Towns Improvement Acts, and many others; and, therefore, he asked the House to allow the consolidated clauses to pass without much discussion and without opposition, and take them on the responsibility of his department; and, with regard to clauses where the construction was doubtful, and the law was in apparent conflict, he would make known to the

House the grounds upon which the proposed construction was placed upon them. The Bill would make better provision as to the construction of sewers, and the local authorities would be empowered to obtain provisional orders under the Gas and Water Facilities Act; but it would not involve any question of competition with private companies, nor interfere with existing compulsory action. Powers would also be given for providing mortuaries in certain cases, and the meaning of overcrowded houses would be defined, which might be the case of one family only. Power would be given to the Local Government Board to group districts for the appointment of medical officers of a less clumsy and difficult nature than at present existed. Some provisions would also be introduced dealing with nuisances arising from smoke and offensive smells, to enable the present law to be more effectually put into operation, and the local authorities would be empowered to take such proceedings as were allowed under the present law whether the nuisance arose within or without their respective districts; and a person who contributed to a nuisance would not be allowed to escape the penalty, upon proceedings being taken against him, by pleading that he was only one of many parties who were guilty of the nuisance. The Bill would in no way interfere with the provisions of the law that had been passed in the interest of trades and manufacturers, but there would be an amendment so as to make the law reach those smoke nuisances that were exempt from the operation of the present law.—The motion was then agreed to.

Friday, February 12th.

Adulteration of Food and Drugs.—Mr. SCLATER-BOTH obtained leave to bring in a Bill to repeal the Adulteration of Food Acts and to make better provisions for the sale of food and drugs in a pure state.

Monday, February 15th.

The Artisans' Dwellings Bill.—On the order for the second reading of this Bill, Mr. STANSFELD expressed his pleasure at the fact that the Government had begun to attempt to legislate on this matter, and said he believed that, consistently with the principles of political economy, a great deal could be done towards improving the dwellings of the working classes. The clauses of the Bill, in their present shape, failed to give effectual power to deal with single houses or groups of houses, and seemed to apply only to large areas. He approved the proposal to limit compensation to the fair market value, and as the property to be acquired would be mostly in a condition that the existing laws condemned, a deduction should be made from the *prima facie* value on the hypothesis that it was fairly chargeable with the cost of putting it in the state the law required. With such amendments as he had suggested, the Bill might leave the House in a practical shape, and form a piece of sanitary legislation creditable to the Government and satisfactory to the country.—Sir S. WATERLOW, while cordially supporting the second reading, hoped to see the Bill amended in various directions. It was to far too great an extent of a permissive character, and rested on the initiative of the medical officers and the vestries.—Mr. RITCHIE thought the Act should apply to small towns and villages as well as to the larger districts; and, in case of the failure of the medical officer or local authority to take action, the ratepayers should have some appeal. There should also be a clause similar to that in the Glasgow Bill, that people must not be ejected without adequate accommodation being provided for them elsewhere.—Mr. WADSWORTH said that, as far as it went, the Bill was admirable; but it did not deal practically with those people whom it was proposed to eject from the terrible rookeries of large towns, for a large portion of them could not pay the rent, for instance, of such places as the Waterlow dwellings. The Bill provided no means of action except by an urban sanitary authority totally neglecting the rural districts. While there were only sixty-four towns with a population above twenty-five thousand, there were five hundred and seven with a population above two thousand; and in the lower rank were places which needed cleansing quite as much as any part of London.—Sir J. HOGG thought that the scheme in respect to the granting of provisional orders was cumbersome. The provision of a standing arbitrator, and that of a fair market value being given for land taken, were most excellent.—Mr. KATHORNE believed that no place more needed such a Bill than Liverpool; and the need of that place had probably had a good deal to do with the framing of the measure. The Bill had anticipated, to a great extent, a memorial which the associated municipalities had resolved to present asking the Government to take steps to amend the present costly and difficult mode of proceeding to acquire such property as ought to be pulled down. The Bill required modification in some respects, and that a greater boldness should be infused into it. Too much, perhaps, had been done in the way of merely pulling down houses, and too little in the direction of improving those that were really habitable. Experiments conducted in London had shown that a great deal could be done in this direction.—Mr. SALT did not see where the

strength lay which was to bring the clauses into practical operation. He alluded particularly to the clause which enacted that the medical officer was to be the person to bring the Bill into working order. As the Bill now stood, it was impossible to form an idea of what expense would be incurred under its provisions.—Mr. S. LEFLVRE expressed general approval of the Bill, but suggested one or two points which he thought required amendment. For example, he was afraid local authorities would be too much exposed to the same sort of opposition as had now to be encountered by private Bills.—Mr. GRIEVE appealed to the Home Secretary to extend the Bill to Scotland.—Sir S. FITZGERALD thought that, in cases where the alterations were positively necessary in the cause of health, they should be insisted on; and that the ratepayers who would benefit by them should contribute largely to the expense. There were portions of large towns where plague spots existed surrounded by houses of a superior description on the same estates, and the same compulsory powers should be given to the owners of these large estates as was proposed to be given to the local authorities, so that they might be able to carry out improvements instead of strangers being called upon to do so. He felt satisfied that the great bulk of medical officers entrusted with the discharge of sanitary duties discharged them zealously and actively, and were not at all likely to become the creatures of local boards.—Mr. JAMES thought the object aimed at should be secured by private commercial enterprise and a vigorous enforcement of the sanitary laws. He was afraid the effect of the Bill in some cases might be to drive the poor from bad dwellings to worse, and to encourage pauperism and ignorance rather than a feeling of independence.—Lord R. MONTAGU regretted the absence of compulsory powers to acquire land outside the towns. It should not, moreover, be left to town councils to execute the Bill, because the most unhealthy buildings generally belonged to town councillors or their friends.—Mr. ANDERSON expressed the hope that the Bill would be extended to Scotland.—Mr. KAY-SHUTTLEWORTH gathered from the debate that the general principles of the Bill were approved by the House. He was only afraid that in London and other towns the authorities would be too much restrained in their operations; and he knew that in Glasgow the persons by whom improvements had been carried out believed it would have been better if they had been able to conduct them over a wider area. The Home Secretary was quite right in entrusting the initiative to the medical officers, who were best acquainted with the fever dens of the large towns. He did not agree with the member for Barnstaple, that this Bill would benefit the wrong classes. The third clause provided for the setting of the Act in motion. It seemed to him that, although the medical officers of health were the proper parties to be entrusted with the initiative, there might be districts in which they were less independent than in other districts; and he thought it would be desirable to have an alternative, and name the medical officers or the local authority. In Liverpool and other large towns there might be no difficulty with respect to the action of the medical officers, but there were other towns in which those officers would shrink from putting the Act into operation. In London, it would be absolutely necessary that the Metropolitan Board should have the power of appointing a medical officer to report where improvements were most needed, but by the Bill that Board had power to appoint such officer only where a special inquiry was instituted in a particular district. And, with respect to the country generally, he saw no reason why, if the medical officer did not set the Bill in motion, the Local Government Board in the country or the Government Board should not send down a medical officer to report. The medical officer was directed to report about a certain area, and no power was given to go beyond that area. Now, he did not think that the medical officer was a proper person to define the exact area, and he would suggest the introduction in the third clause of words giving the local authorities power to include in the scheme such other lands in the immediate vicinity as might be necessary for the improved scheme. He considered the provision with regard to providing dwellings in large towns for those who were dispossessed a very desirable one, but did not consider it absolutely necessary in smaller towns.—Mr. DALRYMPLE joined in the appeal made by other members for Scotland, that the Bill should be extended to that country.—Dr. L. PLAYFAIR joined in urging that the Bill might be extended to Scotland. For the last thirty-four years, owing to various measures of improvement, there had been no deterioration in the mortality of England, but in Scotland deterioration had more than overtaken the improvements. In the chief towns of Scotland, the death-rate averaged, from 1858 to 1859, 26.9, and from 1860 to 1871, 28.2. In other large towns in the same periods it was 23.9 and 24.6. The first principle of the Bill was that it should not be put in operation for civic improvements, but to promote the health of the people. But by what motive power was it to be brought into operation? By the fourth clause, it provided that it should begin on the report of the medical

officers of health. He would be the last to insinuate that they would not perform that duty. Their professional zeal and their known effort to ameliorate the dwellings of the poor would induce the medical officer to take a lively interest in the measure, and to try to put it into operation. But, suppose those efforts met no co-operation from the local authorities, what then? Take the case of Over-Darwen. There they had a local board returned upon a promise of inaction to the ratepayers—a promise not to spend the rates in the improvement of the town. In such a place, what would become of the zeal of the medical officer? Suppose he did move, he would be snubbed, and be told that his interference was not wanted. Being the servant of the local board, his efforts could not possibly be of any use. What made Over-Darwen stir itself at last? A sudden outburst of fever, but, still more, the publicity which its scandalous condition obtained, forced the parishioners to give up their opposition to sanitary improvement, and forced the local board to improve the state of the town. He would suggest—and he intended to put an amendment on the paper to that effect—that, if any medical officer of health reported on the bad state of a locality, and showed that it was unhealthy, and the local board took no action, the local board should be compelled to send that report to the confirming authority, whatever that may be. In the result, an inspector would be sent down to the district to consult with the local medical adviser. The result of that would be that public opinion would be brought to bear upon the nuisance, and the public would benefit. His belief was that the ratepayers throughout the country required to be educated upon the subject; and that, until full knowledge were disseminated, the whole of the advantage to be derived from the Bill would not be reaped. By way of illustrating the vast amount of good which the measure was capable of conferring, he declared that no less than thirty-eight per thousand people died annually in Liverpool from preventable diseases; and that in towns where the dwellings had been improved, consumption had decreased from 40 to 42 per cent. He thought they ought to accept the modest and moderate provisions of the Bill as a step in the right direction.—Mr. CROSS had certainly no cause to complain of the manner in which the Bill had been received. The Bill had very fairly been described as one whose object was the demolition of the fever dens of large towns. All the Bill proposed to do, was to enable the local authorities to get rid of the pestilential dens, and then the rest could be accomplished by means of the existing standing orders. Some honourable members complained that the Bill did not go far enough, while others complained that it went too far. The same remedy would not apply even in the case of all large towns; for instance, there was a difference between London and Liverpool, and different machinery must be applied to meet varying cases. As to the question to whom the authority is to be given to put the power in motion, when he first considered the question, many of the observations that had been made occurred to him. He had had placed in his hands the reports of the medical officers from London and the large towns in the country, and he found they had discharged their duties. He did not think that either the town councils or the medical officers would refuse to do their duty. Those who refused to put the Bill into action took the narrowest view of their own wants and necessities. He thought there should be power given to enlarge the area on the recommendation of the medical officer. He had purposely left out Scotland, because he thought Glasgow and Edinburgh had enough to do under their Improvement Bills, but he had been strongly pressed to apply this Bill to Scotland, and he would take the opportunity of consulting the Lord-Advocate, and, if it could be done, he (Mr. Cross) should have no objection. This Act should be put in force in the best possible practical way. He implored the House not to carry the Bill further than it was intended to go, and not to seek to apply it to purposes for which it was not intended, but he hoped it would be passed very much in its present form.—The Bill was then read a second time; and the Committee fixed for March 4th.

ASSOCIATION OF HEALTH OFFICERS IN LANCASHIRE.—A conference of medical officers of health, convened by the Manchester and Salford Sanitary Association, was held in Manchester on the 12th inst., under the presidency of Dr. Noble, the chairman of the association. Officers of health were present from the chief towns of Lancashire and Cheshire. Derbyshire and Yorkshire were also represented. The object of the meeting was to consider the propriety of establishing an association of officers of health for the north-west of England, with the view of obtaining united action in sanitary matters, and furnishing legislation as to the public health. Such an association was formed under the name of the North-West Association of Officers of Health, under the presidency of Dr. Trench of Liverpool; Dr. Vernon of Southport being the Vice-President.

MILITARY AND NAVAL MEDICAL SERVICES.

INDIAN MEDICAL SERVICE.—The following medical candidates were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School, Netley, February 1875.

1. Stoker, R. H. N.	5290	9. O'Keefe, J. L.	4145
2. Bonford, G.	5222	10. Adams, A. F.	4100
3. Barclay, A.	5206	11. Hume, T.	4087
4. O'Hara, W.	4785	12. Parakh, D. N.	3887
5. Totell, E.	4780	13. Oliver, J. P.	3795
6. Gray, H. A. C.	4410	14. Lewis, J. C.	3734
7. McCarty, C. J.	4348	15. Sweetnam, M.	3515

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Deputy Surgeon-General T. Moorhead, M.D., has been appointed Principal Medical Officer at Hong Kong, on promotion, *vice* Deputy Surgeon-General A. Crocker, who is to be provided for on a home station.—Deputy Surgeon-General T. E. White, M.D., C.B., has embarked on a tour of service in India.—Deputy Surgeon-General Inglis, M.D., C.B., is to proceed from Meerut to Bombay, to succeed the late Surgeon-General O'Flaherty, as Principal Medical Officer of the Bombay Army.—Deputy Surgeon-General Fyrrer, M.D., C.S.I., joins the Senate of the Army Medical School, Netley, by virtue of his appointment at the India Office.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentleman passed his examination in the science and practice of medicine, and received a certificate to practise, on Thursday, February 4th, 1875.

Johnson, William Boyter, 145, Bishopsgate Street, Without.

The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, February 11th, 1875.

Cotton, Herbert, Silent Street, Ipswich
Wye, John Henry, Upper Pitt Street, Liverpool

The following gentlemen also on the same day passed their primary professional examination.

Jackson, Philip John, Guy's Hospital
Mount, Walter, Guy's Hospital
Turner, Walter Pickett, Guy's Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

ALDERBURY UNION.—Medical Officer for the Fourth District and the Workhouse.

ARMY MEDICAL DEPARTMENT.—Surgeons. Applications to be made to the Director General of the Army Medical Department.

PARONY PAROCHIAL HOSPITAL, Barnhill, Glasgow.—Dispenser.

BECKETT HOSPITAL AND DISPENSARY, Earsley.—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coal.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Salary, £80 per annum, with board, washing, and attendance. Applications to be sent in not later than March 3rd.

BRAMPTON UNION.—Medical Officer for the Union and Workhouse. Salary, £50 per annum, and extras, £31 15.

CITY OF LONDON UNION INFIRMARY.—Assistant Medical Officer and Dispenser. Salary, £100 per annum, with board, residence, and washing. Applications to be made on or before the 2nd instant.

CLINICAL HOSPITAL AND DISPENSARY FOR CHILDREN, Manchester.—House-Surgeon. Salary, £60 per annum, with board and residence. Applications to be made on or before March 6th.

COVENTRY AND WARWICKSHIRE HOSPITAL.—House-Surgeon and Dispenser. Salary, £100 per annum, with board, lodging, and attendance. Applications to be made on or before March 2nd.

DERBYSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Board, lodging, and washing, but no salary. Applications to Secretary.

DOVER UNION.—Medical Officer for the St. Mary's District and the Workhouse. Salary, £150 per annum.

DOWNHAM UNION.—Medical Officer for No. 6 District.

DURHAM COUNTY ASYLUM.—Assistant Medical Officer.

EMSWORTH.—Certifying Factory Surgeon.

FLAX MILLS FRIENDLY SOCIETY.—Medical Officer. Salary, £110 per annum. Applications to A. McKeeman, 7, Hunton Square, Johnstone, N.B.

FILLIAM UNION.—Medical Officer for the Fifth District.

GRANTHAM UNION.—Medical Officer for the Ropsley District. Salary, £26 10 per annum.

HALLSHAM UNION.—Medical Officer and Public Vaccinator for the Parish of Heathfield. Salary, £44 per annum, and fees. Applications to be made on or before March 6th.

HARDINGSTONE UNION.—Medical Officer for the Bradfield District. Salary, £45 per annum.

HARRIS, Parochial Board of.—Surgeon. Salary, £66 per annum, including vaccination and medicine for the poor. The gentleman elected will get £200 per annum for attending the ratepayers and cottars within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.

HEADINGTON UNION.—Medical Officer for the Wheatley District. Salary, £70 per annum.

HENDON UNION.—Medical Officer for the Willesden District. Salary, £40 per annum.

HOSPITAL FOR WOMEN, Subo Square.—Physician and two Assistant-Physicians. Applications to be sent in on or before March 2nd.

KILBURN DISPENSARY.—Assistant Resident Medical Officer. Salary, £80 per annum, with apartments.

LANGPORT UNION.—Medical Officer for the Babercy District. Salary, £27 per annum, and fees. Applications to be made on or before March 2nd.

LONDON FEVER HOSPITAL.—Resident Medical Officer. Salary, £200 per annum, with residence, coals, gas, and attendance. Applications to be made on or before March 6th.

MANFIELD UNION.—Medical Officer for the First District, and the Workhouse. Salary, £50 and £40 per annum, respectively.

MILFORD UNION, Co. Down.—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.

MORVEN, Par. sh. of, Argyllshire.—Medical Officer. Salary, £100 per annum. Applications to H. A. Fraser, Morven, N.B.

NAAS UNION.—Medical Officer for the Clane and Tunahoe North Dispensary District. Salary, £125 per annum, and £15 as Sanitary Officer. Applications to be made on or before the 27th instant.

QUEEN'S HOSPITAL, Birmingham.—House-Surgeon. Salary, £50 per annum, with board, lodging, and washing. Applications to be sent in on before March 11th.

REDDITCH AND DISTRICT MEDICAL ASSOCIATION.—Medical Officer. Salary, £150 per annum, with fees and unfurnished house.

ROYAL INFIRMARY FOR WOMEN and CHILDREN, Waterloo Bridge Road.—Physician.

SAFFRON WALDEN UNION.—Medical Officer for the Seventh District. Salary, £86 per annum.

SOUTHPORT INFIRMARY.—Resident House-Surgeon. Salary, £100. Applications to be made on or before March 1st.

ST. BARTHOLOMEW'S HOSPITAL.—Two Casualty Physicians. Applications to be made on or before March 3rd.

ST. JOHN'S WOOD and PORTLAND TOWN PROVIDENT DISPENSARY.—Surgeon. Applications to be made on or before the 24th instant.

ST. LUKE'S HOSPITAL FOR LUNATICS.—Second Clinical Assistant. Board and furnished apartments.

SALOP INFIRMARY.—Assistant House-Surgeon.

SEAMEN'S HOSPITAL.—House-Physician. Salary, £120 per annum, with furnished rooms and attendance. Applications on or before the 22nd instant.

SOUTH ESSEX DISPENSARY.—Surgeon.

ULVERSTONE UNION.—Medical Officer for the Hawkshead District. Salary, £20 per annum.

UNIVERSITY COLLEGE, London.—Curator of the Museums of Anatomy and Comparative Anatomy. Salary, £200 per annum. Applications to be sent in on or before March 6th.

UNIVERSITY COLLEGE HOSPITAL.—Resident Medical Officer. Applications not later than February 13th.

UNIVERSITY OF EDINBURGH.—Additional Examiner in Medicine.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

CONNOLLY, P. R., L.R.C.P.E., appointed Resident Medical Superintendent to the Waterford District Lunatic Asylum, *vice* R. V. Fletcher, L.R.C.P.E.

***Cook, John, M.D.,** elected Out-patient Physician to the Great Northern Hospital.

DAVISON, Francis V., M.B., appointed Resident Medical Officer to the Bridgewater Infirmary, *vice* D. L. Parry, L.R.C.P.E., resigned.

***FITCH, Charles, M.B.Lond., M.R.C.S.Eng.,** appointed Assistant Surgeon-Accoucheur to the Norwich Lying-in Charity.

FLETCHER, Robert V., L.R.C.P.E., appointed Medical Superintendent to the Ballinasloe District Lunatic Asylum.

HAYES, Thomas C., M.B., appointed Physician Accoucheur to the St. Marylebone General Dispensary, *vice* C. E. Squarey, M.B., resigned.

HIGGINS, Wm. H., M.B., appointed Assistant Medical Officer to the Derby County Lunatic Asylum.

HYATT, James T., M.R.C.S.Eng., appointed Medical Officer to the Shepton Mallet District Hospital.

***MAHONEY, F. H. H. Akbar, M.R.C.P.,** appointed Medical Tutor and Demonstrator of Pathology at St. Mary's Hospital, *vice* S. J. Knott, M.R.C.S.Eng., resigned.

SINGLETON, F. E. C., L.R.C.P.E., appointed Resident Medical Officer to the Royal Hospital for Sick Children, Edinburgh, *vice* W. D'O. Grange, M.B.

SMITH, Frederick P., M.B., appointed Medical Officer to the Shepton Mallet District Hospital.

WALKER, William C., M.R.C.S.Eng., appointed Consulting Medical Officer to the Shepton Mallet District Hospital.

WRIGHT, Edward A., M.B., appointed Junior House-Surgeon to the Huddersfield Infirmary, *vice* John Irving, M.B., promoted.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

DEATHS.

***DR NIGEL, Ath-nodore, M.B.Lond.,** at 192, Belsize Road, St. John's Wood, aged 35, on February 3rd.

NICOLSON, Charles Patrick, M.A., M.B., B.Sc.Edin., aged 31, at Forest Hill, on February 9th.

IN consequence of the rejection of the Compulsory Vaccination Bill by the Jersey States last week, a Bill for facilitating voluntary vaccination by the appointment of public vaccinators, was ordered to be considered in a fortnight.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAYSt. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Royal College of Surgeons, 4 P.M. Mr. W. K. Parker, "On the Structure and Development of the Skull".—Medical Society of London, 8.30 P.M. Mr. Spencer Watson, "On the Obstructions of Lacrymal Sac and Nasal Duct"; Dr. C. Theodore Williams, "On a Case of Temporary Paralysis in a Young Female".

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Wm. Marcet, "Contributions to the History of Laryngeal Phthisis".

WEDNESDAY.—Royal College of Surgeons, 4 P.M. Mr. W. K. Parker, "On the Structure and Development of the Skull".—Hunterian Society, Council Meeting at 7.30 P.M. General Meeting at 8 P.M. Dr. Sedgwick Saunders will give his Presidential Address. Dr. R. Clement Lucas, "A Case of Excision of the Ankle-joint"; Mr. N. Davies Colley, C.M., "Two Cases of Diffuse Palmar Ganglion treated Antiseptically".

THURSDAY.—Harveian Society of London, 8 P.M. Dr. J. Milner Fothergill, "On the Treatment of Primary Disease of the Heart".

FRIDAY.—Royal College of Surgeons, 4 P.M. Mr. W. K. Parker, "On the Structure and Development of the Skull".—Clinical Society of London, 8.30 P.M. Adjourned Discussion on Dr. Vivian Poirer's Case of "Paralysis of Serratus Magnus", and Dr. Southey's Case of "Lepra Anaesthetica"; Mr. Pugin Thornton, "Case of Exceeding Infrequency of Pulse"; Mr. John W. Teale, "Case of very remarkable Elevation of Temperature (to 120° F.) after Injury to the Spine"; Dr. Whipple, "Fatal Pleuropneumonia in an Opium-eater".—Quekett Microscopical Club, 8 P.M. Mr. B. T. Lowne, "On the Histology of the Eye".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

J. F. S.—To Abernethy, we believe, is due the sole honour of establishing the anatomical school of St. Bartholomew's. The immortal Harvey was long on the medical staff of the hospital.

THE NEW CHARTER OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS.
SIR,—I must certainly add my protest against the unauthorised declaration that has been made by certain Fellows of the College, dissentients from the proposed new Charter, on behalf of the Licentiates, and am quite of opinion that a new charter, such as has been drawn up by the Committee and approved by the College, is urgently needed. The dissentients, in asserting that it is "an unfounded pretence to put forward as a reason for seeking a new order", "that there are numerous valuable medical appointments in England which can only be held by Fellows or Members of a College of Physicians", assert that which every one knows to be no unfounded pretence whatever, but a fact clearly recognised; that, as a rule, Licentiates of a College of Physicians are excluded from valuable public appointments, for which Members and Fellows are alone eligible.

I think some expression of the feelings of the Licentiates upon a matter which so closely affects their interests might now very opportunely be made through the medium of your valuable columns.—I am, sir, your obedient servant,

NIL TEMERE CREDIDERIS.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

SYPHILITIC INFECTION.

SIR,—Can any of your readers inform me whether instances of syphilitic infection have ever been known to occur through the use, in common, of spoons, cups, glasses, etc.? What would be the effect of drinking from a cup after a man suffering from secondary or tertiary sores on the lips and tongue? We know that nurses' nipples are infected by syphilitic children, but sucking is a more intimate process than drinking.—I am, etc.,

FREDK. J. BROWN, M.D.

H. A. asks: "Which are the two best books on 'Sudden Death and its Causes?' Dr. Granville's work on the subject does not go into causes, or give cases." He adds: "I also want information on the subject of the International Medical Congress to be held at Brussels this year. What is the exact date of its commencement? Who is the secretary, and his address? What are the terms of subscription? And will any account of the arrangements be published soon in the medical journals of this country? I shall feel greatly obliged for information on all the above questions."

ON THE INFLUENCE OF TEMPERATURE DURING CHILDBIRTH.

SIR,—Assuming that labour has commenced, but has not been summarily brought to a close by the kind of preparation referred to in my previous letter, let the patient lie down and cover herself up warm, and go to sleep, if possible, between the pains. Now is the time for absolute quiet and repose: now is the proper time, also, for darkening the room: everything, in short, should be done to encourage warmth and sleep. Better, far better, that she be left entirely alone, than that the slightest noise or conversation should for a moment be tolerated. Now I verily believe that if these conditions were religiously and universally fulfilled, we should hear very much less than at present about difficult and dangerous cases—cases of tedious labour requiring instrumental delivery, and cases of *post partum* hæmorrhage requiring injections of perchloride of iron. Among certain classes of society it is customary for the patient to be delivered in her daily attire. There is an advantage in this which should not be lost sight of. The warmth of the body (especially between the shoulders and around the upper parts of the arm) is thereby better sustained than when the patient is throwing about her arms, covered only by a night-dress—a consideration, according to my view of the matter, of very great importance; so much so, that I have frequently had occasion to advise the patient to put on a warm jacket, for, although she has complained of being oppressed by heat, I have found the upper parts of her body to be cold and clammy. On the other hand, no greater mistake is likely to be committed than that which is sometimes done at the suggestion of the nurse—namely, for a patient, in an interval of labour, to get out of a warm bed and walk about the room in her night-dress. So far from expediting delivery, the adoption of this method, by chilling the surface of the body, is pretty sure to retard the progress of labour for several hours.

Still further to illustrate the all-pervading influence of temperature, I may mention that in cases of retention of the placenta, whether arising from spasm or inertia, I have found it an excellent plan to get the patient to stand before a fire, and thus to warm and dry her body back and front. I have then succeeded in removing the placenta without force, and therefore without hæmorrhage.—I am, etc.,

Harlesden, February 8th, 1875. M.D.

PRACTICE IN THE COLONIES.

The following is something of a curiosity.

Practice resumed.—Dr. Frederick Beer begs to announce that he has resumed practice; and, being a Doctor of Medicine, Doctor of Surgery, and of the art of Midwifery, he is fully qualified to become the medical adviser of families, institutions, etc. As a physician, coming from the most enlightened continental school, he is unapproached by any practitioner in the Colony—a fact which is borne out by the *Lancet* of 1st July, 1871. He will in the prosecution of his duties be guided by fixed principles, of which the following is a summary.

1. His rooms will not be carpeted, nor adorned with hangings, in order that he may keep them absolutely clean and free from the *debris* of fallen morbid matter from cutaneous and other diseases, and thereby prevent them from becoming a hothead for the propagation of disease.

2. His consulting-rooms, as soon as a more suitable dwelling can be obtained, will be in a central but secluded part of the city, free from the incessant noise of traffic, and where alone it will be possible to make correct and minute diagnoses of diseases of the chest.

3. He will not make his practice a mere routine one, nor call oftener on patients than is required; nor will he unnecessarily recommend consultations in the cases of people of means; nor will he consent to consult with any practitioner (though the said practitioner may be legally qualified) whom he knows from the nature of the case to be incompetent to form an adequate opinion thereon. For example, he will not meet a mere surgeon in a medical case, or *vice versa*.

4. He will not accept from druggists a per-centage on medicines supplied by them, nor will he compel his patients to have their prescriptions dispensed in any particular establishment by giving advice therein.

5. He will not attempt to attract and gain support from the vulgar by any external display; such as dazzling equipages, liveried lacqueys, etc.

6. His charges will be regulated by the claims on his time and attention. The following scale will indicate them:—For visits in the city and its immediate suburbs; in medical cases, one guinea; for surgical visits, same distance, half-a-guinea; for full topical examination of the thoracic viscera, with written diagnosis, prognosis, and indications for treatment, one guinea; for ordinary medical and surgical consultations, at his residence, half-a-guinea; servants, on weekly wages, half-price.

As soon as more eligible premises can be obtained, Dr. Beer will give due notice thereof.

2, Cambridge Terrace, College Street, Sydney, 3rd April, 1874.

DR. CAMBELL.—For several centuries the diseases of the eyes were treated by quacks. The late Martin Ware was one of the first who made the ophthalmic branch of the art a peculiar study. The Romans had their oculists—Attius Attimetis and Lyrius being royal oculists, as appears by the following inscriptions on stone: "P. Attius Attimetis, Augusti Medicus ab oculis. Tit. Lyrius, Tiberii Medicus Ocularius."

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

SPIRITUAL MANIFESTATIONS.

THE Eddy Brothers, who live near Rutland, Vermont, have for a long time excited much public comment. Dr. George W. Beard, whose exposure of "Brown, the mind-reader," we published recently, paid them a visit not long since. He writes: "The sum of the matter is, that all of the performances of the Eddy family, except the materialisation of a variety of forms, are old exploded tricks. The key-point of the deception is the physiological flexibility of the family." With regard to the "materialisation phenomena," he says: "They always take place in a light which is almost darkness, and in which no thing but outlines can be discovered. In such a light, practised contortionists, such as the Eddys, could pass themselves off as dwarfs; or, by the addition of a high head-dress and a little stretching, might personate a giant." Dr. Beard unhesitatingly qualifies the "spiritual" phenomena observed as pure trickery. The *successes* are qualified as light, dark, and materialistic. The chief trick in the light *science* is the production of music by supposed spiritual hands. An individual is acted on in each instance. "The medium clasps the arm of the individual in both his hands. A shawl hides the hands of both, and the screen divides the two from the table, upon which the musical instruments lie within easy reach of the medium. This circle completed, a jangling of guitar-strings and tambourine makes a poor apology for heavenly music, and during the interlude a spirit hand is passed gently across the face of the passive party." The individual is convinced that the grasp of the two hands is never once released from his arm, and so concludes that spirits agitate the guitar-strings. "The success of this trick," Dr. Beard observes, "depends on an interesting well known physiological fact—namely, that when the arm is bared and cold hands are clasped on it and pressed hard, the sensation is so benumbed that, if the lower hand be removed, the person operated on will not know it." "The key-points of the deception are the physical flexibility of the family, and the benumbing of the arm-trick in the light *science*. All those who deal with the insane and with criminals know that there are persons so flexible and limber that they cannot be kept handcuffed or tied in any way."—*Philadelphia Medical and Surgical Reporter*.

MEDICAL DEGREES AND TITLES.

SIR,—As one of the much-abused L.R.C.P.E.s, let me draw the attention of the profession to the fact, that while execration is heaped upon us by the fretful M.D.s, not one word is said about the use of the "Dr." by M.B.s. Now, if we have no right to the title of Dr. (which I deny), no more has any M.B.; and yet no one appears to think of questioning the right of these gentlemen to the prefix. I know of several instances where M.B.s are stated to be Drs. in hospital lists, and also in the regulations of medical schools. If we are not legally entitled to the "Dr.," the sooner parliamentary powers are obtained by the Royal College of Physicians the better.—I remain, yours truly,
January 28th, 1875. PISISTRATUS.

SIR,—As custom and courtesy are set on one side by those who write against the Licentiate using the title of "Dr.," and a wish expressed to adhere strictly to the legal view of the case, I would ask if a simple surgeon, or surgeon-apothecary, has a right to the title of "Esquire," or even the prefix of "Mr.," and if a minister, of any sect, to that of "Reverend"? If not, we had better drop them, and hereafter designate the holders of such qualifications as plain John Brown, surgeon-apothecary; or W. Robinson, minister, as the case may be. If ancient usage, custom, and courtesy, do not confer a privilege in one case, it cannot in another. At page 17 of the *Register for K. & Q.C.P.L.*, 1866, is the following: "By ancient usage in this country, analogous to the title of 'Rev.' in the case of a clergyman, and 'Esquire' in that of a barrister, the title 'Dr.' has always been applied to a physician as distinguished from that of 'Mr.' in the case of a surgeon; accordingly, this College applies the title of 'Dr.' to its Fellows and Licentiates whether graduate Drs. or not."—Yours faithfully,
February 1875. THOS. PARKINSON, L.R.C.Q.C.P.L., M.D., M.S.

SIR,—I have just read with some interest a letter in your valuable *JOURNAL* of the 6th instant, signed "A Physician." He has endeavoured to elucidate some points under discussion on the above heading, so far as his side of the argument is concerned. He refers in quite a legal manner to the rights of F. & L.R.C.Q.C.P.L.s—a reference which, I think, is as unnecessary as it is unimportant, since his quotations have been already made use by your correspondents without any weight, and with, no doubt, the same intention. As to the London College of Physicians, it is plain that the worthy Council of that distinguished and most respectable body forbids the assumption of the title of "Dr." by its non-graduate Licentiates—an amendment which was never added to its bye-laws without the mature and decisive consideration of said Council, most of whom, I can confidently state, are luminaries of the profession. As to the opinion which he quotes from the Edinburgh College respecting the title of Licentiates of a College of Physicians, I am "at sea" to know what more convenient distinction could be accorded to them except that of Dr., the possession of which by mere Licentiates of a College would cause University education and graduation to be of no further value, as the Licentiate-Doctors, one and all, would enter upon practice with all the *prestige* of educated gentlemen. I willingly admit that there are Licentiates at present in practice who, both in gentlemanly conduct and professional acquirements, outstrip many graduates of the leading Universities; but I do not mean to convey that they are all of such composition. According to your correspondent, the *Lancet* has some time ago addressed the general practitioners of the United Kingdom in very inviting terms respecting the Edinburgh College of Physicians during the year of grace—a year which, in my opinion, would have been more appropriately termed the year of disgrace. It was a year which caused many L. & M.R.C.S.s to become registrable physicians, many of whom, you will admit, could not have satisfied the most lenient Board of Medical Examiners in the United Kingdom. The year referred to was a fortunate occurrence to many surgeons practising as general practitioners; but, I may add, on the other hand, that it was the reverse to the patients, who are daily placing their lives, when in imminent danger, under the care of such gentlemen, who, they believe, are thoroughly informed on everything connected with the practice of medicine. Your learned correspondent has wound up his letter in a dialogic, but by no means a conclusive, manner. He says that Licentiates do not object to M.D.s calling themselves physicians, and he cannot see why M.D.s should be so severe on Licentiates calling themselves Doctors. Now, the title of Physician is intended to convey that the person who uses such title is duly qualified to practise the science of medicine. The title of Dr., in addition to the foregoing, is also a distinction implying that the possessor of the

same is learned in the highest degree in everything pertaining to the practice of a physician, so that a Doctor of Medicine is plainly more entitled to the prefix "Physician" than a Licentiate of a College—that is, if any preference be given; but it would be thoroughly absurd to answer in the affirmative to the interrogation of a non-graduate Licentiate as his being a Dr. If he can inform me as to what a non-graduate Licentiate is Doctor of, then I will say that I am wrong. All your readers know (at least I expect so) that the assumption of the title "Dr." is illegal *simpliciter* graduation. If a man obtain a Licentiate in Arts Diploma, is that any reason why he should represent himself as having obtained the highest degree in that Faculty, admitting that the acquirements of the former may be equal to those of the latter?

I will not enlarge any further at present on the subject of Medical Degrees and Titles; but if your learned correspondent think he is capable of refuting the opinion which I have set forth, I will be most happy to reply to his communication, just for the purpose of enlightening him and others of his opinion, as I think it the better mode of bringing to a close the correspondence which you have kindly afforded space for in your truly valuable *JOURNAL*.—I am, etc.,
Merthyr Tydfil, February 1875.

THE GOULSTONIAN LECTURES ON PUERPERAL FEVER.

Delivered at the Royal College of Physicians, London.

By ROBERT J. LEE, M.D., F.R.C.P.,

Assistant Physician at the Hospital for Sick Children, Great Ormond Street.

LECTURE I.

MR. PRESIDENT,—The disease generally known as puerperal fever is distinguished by characters which render it peculiarly suitable as a subject for the consideration of such an audience as I have the honour of addressing on the present occasion.

We can trace its history in the literature of medical science more or less continuously from the present time to periods so remote, that we possess now only scanty records of them. In the progressive stages of historical inquiry, we find that puerperal fever, though comparatively a modern introduction into nosological classification, has retained a degree of exactness in its nature which can be claimed by few other diseases, which enables us to recognise it without difficulty in the descriptive works of various authors. It has shared the same fate—or perhaps we ought to say, has enjoyed the same privilege—as those to which I refer, in that it has afforded the student of history the means of determining the character of mind, the method of investigation, the degree of accuracy in observation, and the practical skill which were possessed and exhibited at any particular point of time within the compass of historical records.

Lastly, it may be regarded as the most recent and not least grateful recipient of the favour and advantage which every branch of our science and practice derives from the progress of physical knowledge.

If puerperal fever be thus distinguished, it would seem an easy task to entertain you without fatigue in any one of the lines of research which I have indicated. I am obliged, however, to request that the standard which I regard with deep respect, and you with satisfaction, may be reduced to meet an unusual demand for judgment and caution in dealing with materials so abundantly afforded by past history and recent important researches as to make the satisfactory treatment of them a matter of more than common difficulty.

There is a particular mental attitude, if I may use the expression, which we must assume, in order to arrive at just conclusions regarding the value of the contributions of others to our stores of knowledge of any particular branch of science. It is not easy to avoid a tendency to become partisans of a theory under the influence of evidence which rests upon data beyond our immediate power of verification. To observe and record with accuracy the phenomena of disease, both clinical and pathological, requires much more than ordinary caution and patience when those observations are made for the express purpose of testing the credibility of the opinions of others.

It is desirable to keep in view the general principle that those facts are most valuable which contribute to the practical treatment of any malady, including of course in the term treatment the knowledge of etiology and the best means of prevention. It may be necessary to mention some of the various methods of treatment which have been at times in general repute, though with few exceptions I shall omit those which were of empirical character and ephemeral duration, and cannot be classed with remedies rationally suggested by etiological and pathological considerations, and fairly tested by experience.

It shall be my aim, therefore, when perusing the history of this fever, to prefer those records which contain practical information, and which tend to the elucidation of the origin and real nature of the disease. And, while pursuing this plan, we may with advantage notice instances in which contemporary neglect apparently rewarded most important researches. The effect of thus ascertaining the reception which was accorded to new and original views will be to render us less liable to the disparaging charges which posterity may make against us when present time has become the past—a time which, there are good reasons for believing, will prove not the least distinguished epoch in the future history of the progress of medical science.

I shall attempt to place before you such evidence as is necessary to show that puerperal fever existed very much in the same form as in the present day, at that period which we generally term “classical”, when

nosological distinctions were based upon symptoms, and the modern science of pathology had not been developed, or was entirely unknown.

I may assume, for the sake of convenience, the date of the foundation of this college (A.D. 1518) as the commencement of the modern era, through which we shall trace the successive additions which were made to the general and special knowledge of our subject.

Within the last few years, very considerable modifications have been brought about in our views of contagious agents, in which of course those on puerperal fever have to some extent participated. It is to the chemical investigator and the scientific physiologist that we are chiefly indebted for a series of observations and suggestions which have thrown more light upon the real nature of the fever than we should ever have obtained from ordinary clinical and pathological methods. In fact, it may be said that those sources of information were exhausted. As the conclusions deduced from the observations alluded to are of great practical value, and are receiving constant additions now that so many are engaged in research, it will be necessary for us to examine with patient care the facts presented by the most reliable authorities, and endeavour to ascertain whether they will bear the test of general experience, and how far they afford satisfactory explanations of the causes which produce the phenomena which characterise the disease.

There is one point which must be noticed when we compare in detail the descriptions which we possess of the fever as given by some authors, with the general symptoms which it usually presents in the routine of daily practice. It is the fact that the disease has often appeared in a more acute form, and has been attended by more serious results, than we observe now. Those epidemics, as they were called, which occurred in some of the large cities of Europe and in this country, particularly in the middle and latter part of last century, afford us considerable assistance in explaining these apparent discrepancies, though a complete solution is only to be supplied by an accurate determination of the etiology of the fever. It may seem paradoxical to assert that the disease is a definite one, and yet that we are to be prepared to meet with various descriptions by authors of its symptomatic and pathological characters. If it were not for the fact that many have formed their own ideas of its nature from personal experience alone, and have obtained only a limited view of the many phenomena which it exhibits, it would have been unnecessary for me to direct attention to the reason why we should make some allowance for the difference in details and in opinions which I allude to. There is one way in which we may yield in this respect without going too far, and that is by separating the points of resemblance from those of difference, under the guidance of experience; and by not insisting too strongly on the introduction of the latter into the terms of a definition, we may agree that, both in a scientific and practical point of view, there is sufficient positive evidence to justify us in regarding the disease as one of specific nature.

The Hippocratic treatise known as the *Περί Γυναικείων* contains a general description of puerperal fever, which has been quoted by most writers on the subject. We may supplement it by references to the *De Morbis Vulgaribus*, or *Epidemics*, in which a few cases are related with such clearness and detail as to afford the evidence we require to prove the point in question.

Hippocrates says: “If the lochia do not occur in the puerperal condition, it is very probable that fever and abdominal swelling will supervene. The whole system, but particularly the abdomen, will be highly sensitive to touch. Sometimes there will be intense abdominal and lumbar pain, dislike of food, insomnolence, and irritation of the surface of the body. On the fifth or seventh day after these symptoms, the patient will be attacked with disturbance of the alvine and urinary secretions. If the lochial discharge return, the patient may with proper care soon recover; but, if not, there is great danger that diarrhoea will ensue, and the lochia be arrested. The arterial pulse is weak, though sometimes quick and varying in force. Thus the early stage of the disease is characterised. After a time, the hollows of the face become distended. In this condition, the diet must be light. If there be delirium, laxatives must be given to drink, and other remedies, according to the indications of bilious or mucous secretions. Fomentations and poultices are to be applied daily. If, however, the lochial purgation appear to affect the head, thorax, and lungs, for that may happen, the patient always very soon succumbs.” (Hippocratis *Opera*, Ed. Foes., p. 603, secs. 40, *et seq.*)

This general description applies, as we see, to one particular form of puerperal fever, and, though it is followed by an account of some other forms of disease which we know to be nearly allied to it, and to depend upon the same cause; yet there is no strong indication that they were associated for any reason of that kind in the treatise referred to.

To illustrate the above, in the first book of the *Epidemics*, the history is related of the case of the wife of Philinus, who was seized on the

fourteenth day after delivery with pain in the hypogastric and pubic regions, consequent on the cessation of the lochia. The first symptom mentioned is rigor, or in the original: "She was seized with fever attended with rigors." On the eighth day after this, the rigor returned; on the fourteenth day, she had subsultus and incoherent wanderings, and on the twentieth day she died. (*Op. cit.*, p. 976.)

This case is followed by one still more accurately described. "The wife of Diomedes, having been delivered of a female child, and all other matters progressing favourably, on the second day after was seized with rigor and acute fever. She began to have pain in the hypochondrium and nausea; was incoherent and sleepless for many hours; respiration was long and irregular, and she suffered from thirst, cold sweats, and epistaxis. On the sixth day, she expired." The third case is that of a woman who "was seized with fever soon after the birth of a son. At first, there was thirst, nausea, and cardialgia; the tongue was dry, the bowels disordered; she had slight rigor, acute fever, and a faint cold sweat about the head. On the third day, she was in great pain, and there was diarrhoea; on the fourth day, she had rigors again, and all the symptoms were increased in severity. They continued with slight variation till she died with epistaxis on the fourteenth day." (*Op. cit.*, p. 987.)

Some remarks on the conditions of the atmosphere which existed at the time of the occurrence of this case contain the observation that erysipelas, in a malignant and non-malignant form, was prevalent. There is generally some reason for the introduction of such a fact as this, which is left to the reader to explain as he pleases. The way in which Hippocrates quietly mentions it without remark, still leaves the impression that he had noticed a connection between atmospheric conditions and the occurrence of certain diseases which he could not explain.

There is another important case, which is compared by the commentators with that of the wife of Philinus. The symptoms are regarded as very typical in both instances of the consequences of arrested lochia: a theory, I need hardly mention, which satisfied the minds of the physicians of that day, and indeed for centuries later.

But I do not mention this case, which commences *ἐν Θάσῳ τὴν κατακείμενην*, etc. (*Op. cit.*, p. 1096), for any other reason beyond the fact that, during the period of eighty days of illness terminating in death, we have those symptoms detailed which clearly mark the case as one of phlebitis or inflammation of the cellular tissue of the right limb. The woman was attacked on the third day after delivery with the usual symptoms of puerperal fever, such as were mentioned in the other cases I have related. On or a little after the twentieth day, the symptoms of phlebitis commenced, and the febrile variations which are so commonly met with in this form of disease are simply and clearly stated; they were of a wandering and paroxysmal character (*πελαγημέναι δὲ παροξυσμοῖσι*), which exactly describes them.

Before disposing of the Hippocratic works, it may be allowable to refer briefly to two cases of abortion (*Op. cit.*, pp. 1078-79)—cases, at least, in which febrile symptoms followed immediately on that occurrence. It is right to mention that they are referred to in the annotations of the edition of Foësius as instances of fever producing abortion. There is, however, this peculiarity in the account of the cases which we can hardly regard as without intention. It is, that they both commence somewhat thus:—"This is a case in which acute fever attacked a woman immediately after abortion," etc.; or, "This is another case in which acute fever followed abortion at the fifth month," etc.; and both cases terminated fatally on the seventh day. As it is not the purpose of Hippocrates, in his clinical histories, to connect cause and effect, but to leave the simple facts to speak for themselves, we are not obliged to submit to the conclusions of commentators who have looked at them through the medium of a theory. We are told of the events and symptoms in order of time, and we are permitted to consider the occurrence of abortion related in those cases as certainly presenting a different aspect in connection with the symptoms than if it had been mentioned later in the history.

Independently of these cases, we have the distinct statement, that abortion might be followed by puerperal fever; for we find, in the treatise *De Morbis Mulierum*, such remarks as the following:—"This (puerperal fever) may happen after abortion"; or, again, "Abortions are more dangerous than ordinary parturition, for the uterus is liable to ulceration or inflammation—a condition not serious". It is from such extracts as these and others that most modern authors satisfy themselves of the existence of puerperal fever among the maladies of ancient times. In a treatise by Hulse in 1772, the point seems to have been settled in the opinion of the authors of last century, and his concluding remarks are interesting enough to be quoted as the general expression of opinion at the time referred to. "We have here", he says, "a pretty accurate and plain description of the

puerperal fever, as observed by Hippocrates, which in most parts exactly corresponds with what has been said of it in the first part of this treatise, inasmuch that, had both descriptions been written about the same time, it might have been disputed which author had borrowed from the other. But the truth is, neither of them in the least title copied from the other, but from Nature alone. Hence it is similarity arises; from which also we may learn that the operations of Nature are the same in Britain as in Greece, and continue the same in this day as they were above two thousand years ago. This is likewise a clear proof of the immutability of the puerperal fever, that it is an original disease, and hath been prevalent at all times and in all climates, and yielded to the same method of cure as hath been prescribed above." (Page 95.)

We may assume, then, that there is no great difficulty in establishing the first question of identity in all important particulars. There are one or two points deserving of further notice. It may be observed that Hippocrates omits all mention of treatment in his clinical examples, so that we are unable to determine the extent to which he practised the instructions contained in his general treatise, nor do we feel at all certain that we understand the views which were taken of the essential nature of this fever. It is asserted by his commentators that Hippocrates referred puerperal fever to an arrest of the lochia, the grounds for that assertion being his statement that this is the first symptom of the disease in the puerperal state. There is no doubt that he did entertain some such idea; for he remarks that, "if they"—that is, the lochia—"return, it is a favourable symptom". But the question of the cause on which the local and general disturbances depend is not limited by any means, as some suppose, to the arrest of the lochia alone. There are distinct pathological conditions assigned as causes in a certain number of cases; namely, inflammation and ulceration of the uterus, and retention of placental structures. There is no point more carefully set forth than this, and there is no hesitation in referring the symptoms which follow such retention to the effects of decomposition. "There may be ulcerations in the uterus from the decomposition of the lochia (*Γίνεται δὲ καὶ ἕλκος ἐν τῇ μήτρῳσι οἷα τῶν λοχείων σαπέντων*)" certainly implies this. The word here used we have found necessary to introduce into our own language when we wish to indicate in a special manner the process of decomposition, though it appears to have been commonly used by the Greeks: as, for example, when Hector reported of Hector's corpse:

δαδεκάτῃ δὲ οἱ ἡὺς
Κείμενος οὐδὲ τι οἱ χρῶς σήπεται, οὐδὲ μιν εὐλαί
ἔλθουσι.

"This the twelfth evening since he rested there,
Untouched by worms, untainted by the air."

(*Iliad*, xxiv, 414, Pope's Translation.)

We shall see that the principle involved in our modern term "septic", though clearly appreciated by the ancients, was to some extent lost sight of till almost the present day.

So far as the arrest of the lochia was considered one principal cause of puerperal fever, the theory was naturally applied to the explanation of the various constitutional symptoms noticed in the disease; that is to say, they were simply regarded as of metastatic origin, and their cessation on the return of the lochia was explained by and supported that idea.

Only one other circumstance remains to be mentioned under which the symptoms of puerperal fever may occur, and that is the possibility of inflammation at the ordinary period of menstruation. From what has been extracted thus briefly from the Hippocratic works, we may conclude that several causes were recognised by Hippocrates as capable of producing the series of symptoms which we term puerperal fever, and that amongst those there is evidently a clearly conceived notion of infective agency.

It is not probable, it is quite certain, that the more carefully we scrutinise the classic authors, the more they appear to have known of the symptoms of disease; and their accuracy and acuteness of observation, and, above all, their singular simplicity and truth, command our respect and attention. It is only by some such general expression of appreciation that we can fairly excuse ourselves from a more elaborate analysis than I have offered above. The same kind of sensation steals over the mind in perusing those authors which the works of art of that period produce upon the senses. They exhibit a subtleness of intellect and perception which so astonish and delight, as to make comparison with contemporary efforts never occur to our thoughts, and which hush all feelings of envy into tranquil admiration.

It is not unprofitable, you will agree, to cherish the feeling I have described. It seems long since the Hippocratic writings were seriously studied in this country. We have perhaps been advancing, or at least moving so rapidly, that we have not cared to look back. Yet there

never was a time, I believe, since the period of Grecian excellence, when such true appreciation of its wonderful productions would be developed by a more intimate acquaintance with them than at the present day. Though the knowledge of the phenomena of disease may never have been so complete, their origin and cause so profoundly investigated, as now; though we have the assistance of mechanical, optical, and chemical science to aid in a thousand ways, and may be too much occupied with the present to think of the past—yet we may learn much by studying the too few relics we possess of ancient wisdom and knowledge, as in an equal degree we may acquire taste by contemplating those ruined monuments—silent proofs of genius and skill.

In stating that we are in a position to judge of their merits, I mean to imply that there does not appear to have been any fair critical power exhibited even by the commentators of comparatively modern time. The annotations in the edition by Foesius of Hippocrates's works published in 1621, enable us to ascertain the exact state of knowledge during the long interval; and I may be excused for omitting to make any mention of a period in which science suffered at the hands of her enemies, and was adorned, consistently with Gothic feelings and ideas, in most unbecoming and uncomfortably restricted garments.

From the quotation in Dr. Hulme's treatise, and from those cases to which he omits to refer, it is clear that, so far as symptoms are concerned, all the important phases of puerperal fever were so well described by Hippocrates as to admit of no considerable addition or improvement. It is to the progress of morbid anatomy and pathology that we are chiefly indebted for recent information on the value of symptoms, and their relation to, or origin in, pathological processes. As examples of this, we are able to explain the various local and constitutional symptoms produced by those particular forms of the disease and their occasional complications, which we are accustomed to designate by distinct terms, *e.g.*, phlegmasia dolens, phlebitis, metritis, thrombosis, and others. When I said that we might assume the date of the institution of this College as an approximately correct and convenient starting-point of the modern era, it was intended to fix the attention upon one or two illustrious names which will always in this country be associated with anatomical and physiological science, and which retain their influence in the preservation of our national character of scientific thought and practical purpose.

For the present, we may limit our inquiries to the gradual evolution of the theory now daily gaining ground, that there is a particular cause for the various forms of puerperal fever; *viz.*, the existence of a specific poison in the human system, either introduced or self-developed. It matters not for our purpose what the nature of the evidence was which first led to this belief, provided only that, so far as they went, the data were strictly true and the deductions logical. Our knowledge of the general principle, that we are all more or less under the influence of theories in our practical views of disease, enables us to discern to some extent from the method of treatment the particular theory which any individual maintains on any particular subject, without knowing directly from other sources what that theory may be. Supposing that we have to determine the view entertained by some author of reputation on the nature of puerperal fever, we may ascertain from his directions as to treatment what his theoretical views were, whether chemical, mechanical, physiological, or pathological. This is not perhaps true of most of us, as we rather follow example than theory, and are more under the influence of education than those to whom we are indebted for original ideas. But, as we find there is often antagonism in the mind between the suggestions of a theory and the influence of habit, it becomes necessary to apply the test of treatment to determine how far any individual believes in his theory. In this question of the origin of the belief that puerperal fever depends on a specific poison, we find that the idea is by no means so recent as might be imagined; but, as it was regarded in such a doubtful way as not to influence treatment to any beneficial extent, we cannot admit that it deserves such serious notice as when we meet with those who have entertained the belief so strongly as to have used every endeavour in their power to arrest the influence of the poison, and to prevent its contagious effects. This is the reason for the above remarks. Time has proved that many explanations of the cause of puerperal fever have been erroneous, and that the belief in a specific poison is entitled to general acceptance. Now, if we limit ourselves to tracing its development, which has been sufficiently gradual, we shall be better occupied than in the criticism of erroneous doctrine, and we can perceive that, with such a limited object in view, we may unravel the tangles of history, and, by following one thread, do better than by attempting to begin without an end in hand on this or that knotted loop of conjecture.

In its present form, our idea of the specific nature of the poison which produces puerperal fever is somewhat different from that which

was involved in the "*σῆψις*" of the Greeks; but to what extent it differs, and why, depends of course on our knowledge of the properties of the poison, and that point we need not consider at present. We are not obliged to meet the request to define what we mean by contagious; we should not allow an argument on the meaning of words to interrupt our attention to facts.

I now propose to examine how far the contagious theory of puerperal fever is supported, or contradicted, or neglected by the authorities of the seventeenth century. The theory of a poison generated in the process of the decomposition of organic matter involves the assumption that, *pari passu* with the process of decomposition, there is a simultaneous and equivalent one of generation. This, perhaps, may be going a little too far; but there is no doubt that decomposition and disintegration have always been clearly distinguished. To those who do not reflect upon such questions, the contrast would not seem so striking as to the mind of the scientific inquirer. It is the one, however, which called forth such a request as the following from the pen of Harvey, whom we may regard as the exponent of the most advanced opinions of his day.

"What shall we say of the animalcules which are engendered in our bodies, and which no one doubts are ruled and made to vegetate by a peculiar vital principle? Of this kind are lumbrici, ascarides, lice, mites, syrones, acari," etc.; and then quoting from Aristotle: "For in almost all dry things growing moist, or moist things becoming dry, an animal is engendered." (Page 282, Trans. Harvey: *On Generation* (Sydenham Society's Works).)

In another place, he exclaims: "Let physicians, therefore, cease to wonder at what always excites their astonishment; namely, the manner in which epidemic, contagious, and pestilential diseases scatter their seeds, and are propagated to a distance through the air, or by some *fomes* producing diseases like themselves, in bodies of a different nature, and, in a hidden fashion, silently multiplying themselves by a kind of generation, until they become so fatal, and, with the permission of the Deity, spread destruction far and wide among man and beast" (p. 322, *op. cit.*). There can be no doubt of the views of the author of these passages regarding the development of minute independent organisms in the human body; and, though we have made considerable progress in our powers of demonstrating forms of life of minute dimensions since his time, yet, for practical purposes, he had so clear an idea of the probability of the existence of almost atomic germs, that he would not only have believed the statements of Professor Tyndall, but have followed that distinguished experimentalist to the extreme limits of imagination. He would have agreed with the description of the poet:

"Unfinished things one knows not what to call,
Their generation's so equivocal:
To tell them would an hundred tongues require,
Or one vain wit's, that might an hundred tire."

Essay on Criticism, part i.

There is all the proof which we require of Harvey's belief in the effects of a poison generated by decomposition to be found in a subsequent passage in his work *Generation*; and, as it is an important one in many ways, particularly in a practical point of view, I shall with your permission quote it at length.

"Women, as they alone have a menstruous, so have they alone a lochial, discharge; added to which, they are exposed to disorders and perils immediately after birth, either from the uterus, through feebleness contracting too soon, or from the lochia becoming vitiated or suppressed. For it often happens, especially in delicate women, that foul and putrid lochia set up fevers and other violent symptoms; because the uterus, torn and injured by the separation of the placenta, especially if any violence have been used, resembles a vast internal ulcer, and is cleansed and purified by the free discharge of the lochia. Therefore, do we conclude as to the favourable or unfavourable state of the puerperal woman from the character of these excretions.

"For, if any part of the placenta adhere to the uterus, the lochial discharge becomes fetid, green, and putrid; and sometimes the powers of the uterus are so reduced, that gangrene is the result, and the woman is destroyed. If clots of blood, or any other foreign matter remain in the uterine cavity after delivery, the uterus does not retract nor close its orifice, but the cervix is found soft and open. This I ascertained in a woman, who, when labouring under a malignant fever, with great prostration of strength, miscarried of a fetus exhibiting no marks of decomposition, and who afterwards lay in an apparently dying state, with a pulse scarcely to be counted, and cold sweats. Finding the uterine orifice soft and open, and the lochia very offensive, I suspected that something was undergoing decomposition within. Whereupon I introduced the fingers, and brought away a mole. . . . The woman was immediately freed from her symptoms, and in a short time recovered." (*Op. cit.*, p. 544.)

On the principle advocated by Harvey, that we do well to treat with respect the opinions of the past, I have made these extracts from his work on *Generation*. He observed that "respect for our predecessors and for antiquity at large inclines us to defend their conclusions to the extent that love of truth will allow. Nor do I think it becoming in us to neglect and make little of their labours and conclusions, who bore the torch that has lightened us to the shrine of philosophy." (*Op. cit.*, p. 432.)

In order to ascertain how far the ideas of Harvey on the connection between puerperal fever and decomposition were entertained generally, we cannot refer to a better authority than the celebrated French obstetrician François Mauriceau. In his remarks on the suppression of the lochia, and the symptoms which are produced by it, he says that "those putrefying humours, by reason of their prolonged detention in the cavity of the uterus, produce for certain considerable inflammation, so that the suppression of the lochia may be one of the most dangerous symptoms which can happen in the puerperal condition". (Ed. 1681, p. 284.)

The most important pathological effects of inflammation are described by Mauriceau, nor does he omit to mention the symptoms of puerperal phlebitis, attributing that also to the suppression of the lochia. This idea led him to depend upon bleeding as the chief remedy for the disease: so that we can hardly say he had any conception of the existence of a poison generated in the process of decomposition as the prime cause of these symptoms. As a clinical observer, however, he mentions in detail the most minute as well as the leading symptoms of nearly all the forms of puerperal fever with which we are acquainted; at least of those which occur in the puerperal condition, properly speaking. It is rather in his character of a practical physician that we must regard him than in that of a scientific pathologist.

I have already indicated to what extent simple clinical observation is able to explain the etiology of puerperal fever; and, for the reason that pathological analysis had not been brought to bear upon it till a century or more after Mauriceau's time, we have no important addition to notice in the works of intervening authors.

Changes had taken place, however, in the general doctrines of medical science during that period, and these necessarily more or less influenced general opinion on the etiology of our subject. I have used the term *pathology* in the sense in which we employ it at the present time, or at least in that sense which we attach to the term *morbid anatomy*. It had a different signification, however, a century ago, when Cullen said, in his lectures, "The pathology that I am to deliver is properly to be referred to two heads— that of causes and that of symptoms;" and again, "When we speak of the pathology of a disease in the institutions or in the practice of medicine, the disease is considered in its symptoms, causes, and effects." The term thus may be seen to have included the etiology as well as all the phenomena of disease.

As far as puerperal fever is concerned, we have only to notice in Cullen's works certain views which he entertained on the general question of the difference of fevers and their causes, and which were intended to apply to puerperal fever amongst others of contagious nature. It is his theory of contagion that we are induced to examine, and not any additions to the morbid anatomy or the symptoms of puerperal fever by himself or his immediate predecessors, that deserve our attention. The term *fomes* was used by Harvey to describe a minute organic particle, one of the products of decomposition, possessing very active properties, though certainly indefinite in its character. This term is also used by Cullen in much the same sense. He assumes the existence of different kinds of fomites, of different specific nature, and suggests the employment of the term *effluvia* "rather than the general ones of contagion and miasma". By *effluvia* he meant the products of the decomposition of any animal matter, as distinguished from contagion and miasma; miasma being the product of the decomposition of vegetable matter, and contagious being a term used to distinguish such diseases as scarlet fever, measles, and others, not originating in a decomposing process. Such I conceive to have been the meaning of *effluvia*, contagion, and miasma: "Substances", in his own words, "thus imbued with an active and infectious matter may be called fomites; and it appears to me probable that contagions, as they arise from fomites, are more powerful than as they arise immediately from the human body."

"The miasma", he says, "so universally the cause of fever is that which arises from marshes or moist ground acted upon by heat;" the word fever, as arising from miasmata, being restricted to the intermittent species. He defines "contagions as arising directly or originally from the body of a man under a particular disease, and exciting the same kind of disease in the body of the person to whom they are applied." (*Præticæ*, vol. i, p. 80, *et seq.*) From these passages, it is not

difficult to understand Cullen's idea of fomites, though, as far as having proved the existence of such particles, he was not the least more advanced than his predecessors; that is to say, his reasons for believing in such germs of disease rested entirely upon clinical observation.

He found some difficulty, however, in dealing with a class of fevers or pyrexia known as "continued", jail, or hospital fevers, and in this class he included puerperal fever. He attributes their origin to a common cause. On this point, it will be seen that there was a definite opinion regarding the effects which may be produced by the effluvia from the living human body, which, "if long retained in the same place without being diffused in the atmosphere, acquire a singular virulence, and, in that state being applied to the bodies of men, become the cause of a fever which is highly contagious. The existence of such a cause is proved by the late observations on jail and hospital fevers, and that the same virulent matter may be produced in many other places must be sufficiently obvious." With respect to these contagions, Cullen observes in another place: "Though we have spoken of them as a matter floating in the atmosphere, it is proper to observe that they are never found to act but when they are near to the sources from whence they arise; that is, either near to the bodies of men, from which they immediately issue, or near to some substances which, as having been near to the bodies of men, are imbued with their effluvia, and in which substances these effluvia are sometimes retained in an active state for a very long time."

With such views of the origin of what we now term septic causes of disease, we may expect that the treatment recommended by Cullen was consistent with those views. There is so little empiricism in his admirable works, and he always leads up to the subject of treatment in the most logical manner after a careful analysis of the symptoms and probable nature of any disease, that we are not surprised to find that he avoids those discussions which many of his contemporaries indulged in. It was not a question for him whether to bleed or not to bleed was right, nor would he have recognised any statistical contributions to the determination of that question as of much value. While as for special remedies, unless they were known by experience to produce such effects as would theoretically assist in the consistent working of his idea of the cause of the fever, would he have paid attention to them.

Cullen was not the man to be deceived by the representations of success which were reported to have followed the use of ipecacuanha in puerperal fever, in a memoir by Dr. Doulet of Paris, the publication of which was made the year before Cullen's last edition was issued. His own directions for treatment, which we will notice presently, were based upon the view, "that the cause of death in fevers may be a poison; that is, a power capable of destroying the vital principle; and this poison may be either the miasma or contagion which was the remote cause of the fever, or it may be a putrid matter generated in the course of the fever. In both cases, the operation of such a power appears either as acting chiefly on the nervous system, inducing the symptoms of debility, or as acting on the fluids of the body, inducing a putrescent state in them." (Section 101, *op. cit.*) In other words, a "strong tendency to putrefaction in the fluids" was "the direct cause of all the phenomena of these fevers." (Section 102, *id.*)

Thus far I have advanced by rather rapid strides in the history of the most important part of our subject. I have referred to original sources for information, and have not attempted, under the influence of any feeling, to make it appear that the authorities referred to knew more or less than they could fairly claim to have known. I have omitted almost all mention of a great deal that has been slowly dismissed from that total of data which we feel is more essential to correct conclusions than the assistance of the most powerful logical reasoning. We have arrived at a time when our modern system of medical science was beginning to develop itself; when attention was being directed to those new and unexplored regions which the researches of the morbid anatomist and pathologist have since exposed to our view. To what extent those new methods of inquiry modified the general ideas concerning the etiology of puerperal fever, I shall proceed to consider in the next lecture.

ANIMAL VACCINATION.—Since 1872, there has existed in the *abattoirs* of Bâle a vaccine establishment, headed by a veterinary surgeon, which is used by all classes of society. Bulls are inoculated with vaccine from children, and in their turn serve as foci for vaccination. After having shaved the posterior face of the testicles of these animals, about twenty superficial incisions, from two to three centimètres long, are made with the instrument charged with vaccine matter. If done carefully, the operation always succeeds, and, at the end of the sixth day, it is possible to collect vaccine, which, mixed with glycerine in the tubes, preserves its properties longer than human vaccine.

THE ETIOLOGY OF PUERPERAL FEVER.

By ROBERT E. HUNTLEY, M.D., Jarrow-on-Tyne.

I AM induced by the letters signed "Obstetricus" and "Junior" to offer a few observations on the above subject.

In the BRITISH MEDICAL JOURNAL of August 5th, 1865, I gave details of a number of cases of puerperal fever, which had occurred in my practice a few months previously. It was manifest that the outbreak was in some way associated with me, for it was exclusively confined to my practice, notwithstanding there were four other practitioners in our town. I took all the precautionary measures usually adopted to eradicate the disease, such as baths, changing of clothes, but all to no purpose. I eventually went over to Ireland, and remained there six weeks, after which time I returned, in the confident hope that no chance of my transmitting the disease remained. Nevertheless (and "Obstetricus" should note this), the first two or three cases that I attended showed unmistakable signs of infection, and I was compelled, by the serious consequences, to cease the practice of this branch of the profession for a further period. From my sad experience, then, it was apparent that the obstetrician should relinquish practice during not less than two months. But, when such fearful consequences are involved, it is safer to overestimate rather than underestimate the time; and such was the advice I gave to a midwife who recently lost, to my knowledge, not fewer than four cases within two or three weeks. The frequent ablutions which medical men necessarily undergo make it absurd to suppose that for weeks the *materies morbi* can be communicated by the hand of the accoucheur; and, when a change of clothing takes place, we may reasonably conclude that all chance of infection from this source is avoided. As further proof of the fallacy of this belief in the production of the disease by this means, I may cite the rarity of our ability to trace puerperal infection distinctly to these causes.

I left under the charge of my *locum tenens* several cases when I went from home, yet not a single case occurred among all those he attended in my absence. I find that there is a chimerical fear prevalent among physicians regarding this method of contagion, which oftentimes impels them to act inhumanely. Lately, I was called in to see two cases attended by the midwife abovementioned. I found that the friends had already sought the assistance of medical men, who decidedly refused to attend, because the cases were of this nature. I and my assistant took charge of these patients (one of whom died after a few days; the other, though still under treatment, is slowly recovering); and I see no reason to regret placing them on our list, as no evil consequences have followed to any of the confinements since attended by us. Hence, and from repeated experiences of this kind, I infer that such a mode of contagion is rare. That it does happen occasionally, I have no doubt; but, with due caution, as by abluion on leaving a patient thus affected, and by allowing some time to elapse between visiting patients where there is a possibility of infection, the risk is exceedingly small. The cases related in the JOURNAL of February 13th, by Dr. Fenton, would seem to disprove this opinion; but it is by no means certain that the bedclothes in the instances related by him were the source of contagion. I rather incline to the belief that the midwife afforded the fell influence, or was the source from which the poison was derived. Otherwise, burn the bedclothes and set the woman free.

From these considerations and facts, it seemed plain to me then, and I see no reason why I should change my opinion now, that we must look for some other means of communication of the *materies morbi* than that generally accepted by the profession; and, guided by the experience then gained, I advanced the only theory which commended itself to me, viz., that the contagious influence was somehow intimately associated with the *person* of the obstetrician, and not with his surface or clothing only. It is true that I was unaware of any morbid condition then existing in my own constitution which would be likely to give rise to any morbid exhalation, and fortify me in the belief entertained. Still, it is possible that, unobservable to myself, there may have been present some defect in the assimilating process, some error in the secretory or excretory systems, which would generate a morbid material capable of producing septicæmia. It may be, however, that the toxic matter is not generated *de novo* in the system; but, being received from external sources in the first instance, becomes propagated by some unknown means. What I seek, however, mainly to establish is, that the clothes theory is untenable. As to whether the obstetrician can communicate this disease without vaginal examination, I have no definite opinion, not being able to call to mind any instance in which it has happened; but, with views such as mine, such an occurrence would appear by no means unlikely, indeed, nearly as likely as if the whole process of delivery had been under the superintendence of the ac-

coucheur, *i.e.*, presuming that he had been at any time in close contact with the patient.

It is of vital import that the obstetrician should recognise at the very earliest stage the true character of the malady; and the points to which, in my opinion, attention ought to be directed, are the various causes from which puerperal fevers originate. These may conveniently be divided into three classes.

1. Those originating in the patient herself, as general unhealth giving rise to inflammation of the uterine and peritoneal structures, or such as spring from intrauterine causes, putrescence of the infant or of the other contents of the uterus.

2. Such as spring from atmospheric influences, and give rise under ordinary circumstances to fevers, as scarlatina, typhoid, and typhus.

3. That lamentable and malignant form mysteriously communicated by the accoucheur.

Cases of the first class are frequently easily diagnosed, though cases will arise from this cause which may baffle the most expert. As regards the second class, a good, and perhaps the only reliable, guide, is the prevalence in the district of fevers of an epidemic nature. I am of opinion, however, that the epidemic or typhoid form of puerperal fever does not always coexist with the prevalence of typhus or typhoid, but that there is some meteorological condition conducive essential to its production. In all these cases, though the *materies morbi* may not be identical, yet blood-poisoning is the result, and the symptoms are only modified by the constitutional peculiarities and condition of life of the patient.

It has occurred to my mind that, assuming this theory of the production of puerperal pyæmia by the obstetrician, as asserted by me, to be true, it would be matter for serious thought, whether, in the event of a second outbreak in the practice of one man, he should not entirely relinquish obstetric practice, the second event arousing suspicion that there might be some special disposition existing conducive to the production of this fatal disease. I should so act myself.

As most important in preventing the spread of the disease, it is evident that some efficient and organised system of espionage is imperative.

I have become aware in my short experience that many deaths have occurred through want of knowledge and due appreciation of the gravity of the consequences likely to follow from persistence in midwifery practice, in the vain hope from day to day that the disease will disappear. Ignorant midwives, and young practitioners who may not have been taught to recognise the peculiar features of this special form of disease, are very prone to fall into this error. Now that officers of health are (or ought to be) generally established in every district throughout England, it should be deemed by the Privy Council one of the chief duties of such officers to investigate the true nature of any epidemic of puerperal fever coming to their knowledge, and to consult with, or advise, the propagators of the mischief. A stumbling-block would, I suspect, be often placed in his way by the fact that the most important means of information—the books of the Registrar of Deaths—do not always furnish a true record of the cause of death, when it is puerperal pyæmia. This is no idle statement, but one which I have verified by reference to the returns in this district, when I have found only two deaths returned as from this cause during two months, when I have had satisfactory knowledge of the occurrence of at least eight. The tendency to observe secrecy in such cases is a fact intelligible, and to some extent, perhaps, excusable. From this point of view alone, I regard the late Sanitary Act as a wise measure, calculated to prevent much human suffering, and to save many valuable lives.

When, ten years ago, I enunciated the theory I have expressed above, the proposition did not elicit any discussion. Possibly, it was deemed unworthy even of notice; yet I feel confident that in the future it will be recognised as by no means so improbable as superficially it may appear to be.

There are many occult problems connected with the etiology of disease, which suggest themselves every day, that are not less strange than that now propounded, and yet they meet with favourable consideration. The theory of transmission from extraneous sources, I grant, at first sight would seem most probably true; yet, in the minds of those who may unfortunately have the opportunity that experience affords, I feel certain that grave doubts of its validity will arise.

THE Ryan Prize, value £100, offered about two years since by the Board of Trinity College for the essay that would produce from the Bible the best argument for the truth or Divine origin of Christianity, has been awarded to a member of the profession, Dr. Isaac Ashe, Medical Superintendent of the Londonderry District Lunatic Asylum. Dr. Ashe obtained the second Carmichael prize, value £100, in 1868; and the first Carmichael prize, value £200, in 1873.

ANOTHER CASE OF POISONING BY HOMŒOPATHIC CAMPHOR.

By GEORGE JOHNSON, M.D., F.R.S.,

Professor of Medicine in King's College; Physician to King's College Hospital.

I AM indebted for the particulars of the following case of poisoning by homœopathic solution of camphor to my friend Mr. Gooch of Eton. He had read my last paper on the subject in the JOURNAL (Feb. 6th, 1875), and, thinking that the case of an Eton boy whom he had attended some time since would interest me, he has been so good as to send me a brief report, with permission to publish it in the BRITISH MEDICAL JOURNAL. The following is Mr. Gooch's narrative.

"About three years since, I was called to see an Eton boy, aged 14, who was supposed to have fainted. I found him lying on his bed, almost pulseless, and quite insensible, with his extremities cold, and his face and lips pallid. He had shortly before had his dinner, and I thought that, perhaps, he might be suffering from an attack of indigestion. Whilst I was administering stimulants, and applying hot bottles, etc., to his feet, a servant accidentally found a small bottle on his table, which was labelled, 'Rubini's Homœopathic Camphor'; and, thinking that he might have taken some of its contents, I gave him, with difficulty, an emetic. This had the immediate effect of causing him to vomit his dinner, which was mixed with an immense quantity of camphor, which scented the whole room most powerfully. In about half an hour, he became sensible, and told me that he had a cold, for which he had purchased the camphor; but, instead of dropping two or three drops upon a lump of sugar, as directed, he poured it out on the sugar, and after taking it, immediately became insensible. In the evening, all the effects of the drug had gone off; he passed a good night, and had no unpleasant symptoms afterwards.

"He was a strong, healthy-looking boy. The bottle found in his room was very small, holding about half a drachm, and it was about half full when I saw it; so that he may have taken about fifteen drops of the solution, if an ordinary lump of sugar would hold so much."

This is the seventh case of poisoning by the homœopathic concentrated solution of camphor that has come to my knowledge during the last two years. I suspect that, if all the cases of this kind that have come under the notice of the profession within the United Kingdom during the same period were published, the list would be a very long one, and it might serve as a warning of the danger which attends the incautious use of this highly concentrated poison.

Since the above was written, I have read with much interest the two cases published in the last number of the JOURNAL (p. 243), by Dr. Legat and Mr. Ellerton.

ON SOME POINTS IN THE DIAGNOSIS OF BRIGHT'S DISEASE.

By CHARLES MACLEAN, M.B., Applecross.

It may appear a work of supererogation to speak of the powers of the microscope in the investigation of renal disease, but we really cannot be too much impressed with the value of that instrument in diagnosis; and the chief object of this paper is to show how it can be made the principal medium in the performance of a delicate test towards the detection of true albuminuria when the urine contains blood. Bright's disease may easily be complicated with hæmaturia—indeed, it is often so; and it frequently becomes a question, whether the albumen in the urine of a patient is or is not to be explained by the presence of effused blood. We have, in fact, to find out how much blood-albumen the urine contains, and how much albuminuric albumen. The former can be estimated by counting the number of red blood-corpuscles to be seen on a given extent of the microscopic slide; it being known how much albumen, say in the ounce of urine, shall correspond to a given number of discs. The amount of albumen in the urine is easily found by coagulating, filtering, and drying that contained in a like quantity of urine (an ounce), and weighing it.

I find that, when forty blood-discs are to be seen in the whole field of an "Oberhauser" microscope, using object glass No. 7 and eyeglass No. 4, if there be effused blood in the urine, the albumen contained in an ounce, on being dried, weighs one grain; therefore, whatever there is of dried albumen from the ounce of urine, over and above the proportion of one grain to the forty blood discs, seen as above, must be the product of true albuminuria. I have a case of granular disease of the kidney in which the albumen obtained from one ounce of the urine, independently of blood, weighed eight grains when I saw it first.

It would be as fallacious to look upon coagulation by heat and nitric acid as conclusive of a case being one of albuminuria, without taking other circumstances, such as the presence of blood, etc., into account, as it would be to exclude the possibility of that disease being present merely because of the urine containing blood. It may be mentioned, that the urine has a distinct tinge of blood when as few as ten discs are to be seen on the field of the microscope. I had occasion to examine the urine of a lady, a visitor in this neighbourhood, who, before she left home, received a note from her medical attendant saying that she had had a severe attack, in which the noticeable symptoms were dark smoky-looking urine, which contained blood-discs, and which coagulated distinctly on the application of heat—essentially a tautological statement. The coagulation was twice referred to as an important point; whereas I think it quite likely that, if a test of the kind described in the foregoing remarks had been applied at the time, it would have been found that hæmorrhage sufficiently accounted for all the coagulation. I found the urine quite natural in every way, except that it contained great numbers of crystals of oxalate of lime; and the conclusion to which I came was, that the bleeding had been caused by a concretion of oxalate of lime forming in the kidney.

The importance of examining the urine in the diagnosis of disease cannot easily be exaggerated. The facility with which we obtain evidence in this way, and the certainty of the information when obtained, make the omission on our part of this means of diagnosis the more inexcusable. I was recently called to a case, in which the only observable symptoms were epigastric pain, nausea with feeling of great weakness, and a subacute bronchial affection. As the latter complaint did not appear to me to be capable of accounting for the constitutional symptoms, I examined the urine and found it loaded with albumen; and the microscope revealed numerous granular casts. All doubt as to the nature of the disease was thus at once dispelled. There was here not the least lumbar pain complained of, and no unusual feeling on micturition.

I had an instance of the great value of the microscope some time ago in a case of hæmaturia. It was an alarming case; and life seemed at the time in danger from the large quantity of blood lost, for pint upon pint of bloody urine (or, more properly speaking, of diluted blood) was passed. I gave the patient gallic acid to begin with, until I should examine the urine microscopically. This treatment made little or no impression, however; and, when I brought the microscope into use, I found crystals of the ammonio-magnesian phosphate in abundance. Thereupon I combined sulphuric acid with the gallic, and the almost immediate result was an abatement of the bleeding. The mineral acid probably dissolved any irritating particles of the triple phosphate that may have formed. The patient had a milder attack afterwards, but it yielded readily on the application of the same remedy.

THERAPEUTIC USE OF THE CONTINUOUS GALVANIC CURRENT.

By THOMAS E. CLARK, M.D.,

Late Physician to the General Hospital, Bristol; and formerly Surgeon to the Royal Infirmary, Bristol.

I SEND three cases treated by myself by the continuous galvanic current, believing that it is a subject of interest to the profession.

CASE 1. *Endometritis cured by the Continuous Galvanic Current.*—S. H., aged 39, a married woman, has had four children. After her fourth confinement, she suffered severely from leucorrhœa, bearing-down pains, tenderness in the left iliac region, and dysmenorrhœa. This continued for six months, when she was able to go about the house; this was in 1870. I saw her in June 1871, and, upon examination, found the fundus uteri lying obliquely and to the left, the os uteri patulous, and superficially ulcerated; and, during the introduction of the speculum, a porter-coloured fluid of a very offensive character flowed from the os. Under the local use of nitrate of silver, and the internal use of bromide of potassium, iron, and sumpul, with rest, she became very much better, and indeed reported herself well. However, in the November following, she caught a severe cold, and all the old symptoms recurred. She was now confined to her room and bed, and no treatment seemed to have any beneficial effect upon her case. I saw her in June 1872, and ordered her away for a time to recruit her shattered nervous system, and at intervals of a week, applied the nitrate of silver: she also continued the bromide of potassium and iron mixture. At the end of August she returned home, and I recommended the continuous current, with the idea of altering the secreting property of the lining membrane of the uterus. Accordingly, I introduced a partly insulated wire into the cavity of the uterus, and attached

it to the negative pole; the positive was connected with a moistened sponge, and applied over the pubes for twenty minutes. This was repeated three days; after which treatment, I had the satisfaction of finding that the offensive discharge ceased, and never returned. It was some months, however, before the hysterical condition subsided; but now, after two years, she has continued perfectly well, and is able to undertake all her usual household duties.

CASE II. Lipoma cured by Electrolysis.—A. A., aged 66, had a fatty tumour over the left shoulder. Thirty years ago, a fatty tumour was removed from the upper part of the left shoulder, and soon after the healing of the wound, a small swelling was observed close to the cicatrix; this caused no pain, and grew very slowly till within the last eighteen months, when its growth was more rapid, the skin becoming thin and shining, and two ulcers formed, one of the size of a two-shilling piece, and the other of the size of a shilling. In 1868, the patient had the appearance of being deformed, having a large swelling over the left shoulder, extending from the spine of the scapula upwards, and outwards to the acromion, measuring twenty-one inches in circumference, and fourteen inches transversely from base one side to the base on the other. There were two ulcerated patches as above stated, the skin appearing extremely thin, and large veins crossed its surface. The feel was semielastic, and pressure produced a lobulated appearance. I suggested its removal by the knife, but this she declined. I then advised the continuous galvanic current, and she decided to try it. A battery of sixteen cells was the one used. Three needles were passed into the tumour at its circumference, and connected with the negative pole, the circuit being formed by means of a moistened sponge attached to the positive pole, and placed on the tumour. The application lasted twenty minutes, was repeated at intervals of a week or fortnight; and, after four applications, the size had decidedly lessened, and the ulcers entirely healed. The process was continued in all fifteen times, and varied in duration from twenty to forty minutes. The only sensation complained of was a sense of heat; there was no bleeding, and the patient, who came from a distance, was in no instance prevented from returning. The time occupied with this case was nearly twelve months, and, at the end, the tumour had entirely disappeared, leaving only a small hardened portion, not larger than half a walnut.

CASE III. Prostatorrhæa cured by the Continuous Galvanic Current.—R. S., aged 45, had suffered severe dragging pain in the perineum and around the back and groins, coming on after micturition or defæcation, and lasting several hours, although he was seldom free from a sense of discomfort; there was also a mucous discharge from the urethra during the act of defæcation and at the end of micturition, with a feeling of burning pain along the urethra, and this would continue for several hours. He had been under treatment for two years before seeing me. I examined the urethra; No. 10 catheter passed easily without pain, except over the prostatic portion. The finger in the rectum demonstrated a flattened elongated prostate. He was greatly depressed from the continual suffering. I tried a variety of treatment; suppositories of opium and belladonna; the bromides with bark, etc., but to no purpose. There were several consultations held (one gentleman saying he believed it was malignant disease of the prostate). After some months of suffering and no benefit from remedies, I determined to try the continuous current. Applying the negative pole in the rectum, and the positive, a moistened sponge, to the perineum, I continued it for five or ten minutes. This was repeated a dozen times, and the patient's trouble entirely disappeared. This was at the end of 1873, and he has since continued in perfect health.

ON THE CAUSES OF DEATH AFTER OPERATION FOR STRANGULATED HERNIA.*

By F. H. EDMONDS, L.R.C.P.Lond., Rochester.

ABDOMINAL hernia being unfortunately a common disease, and the strangulation of a hernia being sudden in occurrence and rapidly fatal in its course, we, as general practitioners, have to be prepared to meet it at once, and to undertake its treatment without the advantage of a consultation with a surgeon, fortunately permitted us in other surgical diseases. It is, therefore, necessary that we should pay every attention to the detail of all cases coming under our care. In the following four cases, the operation was performed by Dr. F. J. Brown in three, and by Mr. Nankivell in one; and I have to thank these gentlemen for their kindness in permitting me to lay them before you, and direct your attention to the points which appear to me of practical interest. My connection with the cases was that of administering chloroform and making the *post mortem* examination.

* Read at the West Kent District Meeting.

CASE I.—Amos Saywell, aged 24, admitted to St. Bartholomew's Hospital, Chatham, on September 5th, 1870, had suffered from inguinal hernia for some years, and had been once before relieved at the hospital by taxis. The operation was performed by Dr. F. J. Brown, twenty-four hours after strangulation, twenty-two hours after admission, under chloroform. The sac was opened. About one hour after the operation, the patient vomited a quantity of fecal matter, with large quantities of serous fluid. Mr. Nankivell and myself being at the bedside, we gave brandy. The vomiting continued; and, as the patient seemed to be choking, we used Silvester's system of artificial respiration for a few minutes; but the patient died, with marked symptoms of apnoea.

POST MORTEM EXAMINATION, thirty-nine hours after death.—Rigor mortis was strongly marked. Sero-feculent matters issued from the nostrils. The right pleura contained about one pint of fluid; the left pleura was toughly adherent to all the walls of the thorax. The right lung contained a quantity of fluid in its bronchi, of the same character as that vomited; the left lung contained a little fluid of the same nature. The hernia had been reduced. There was a small spot of congestion on the convexity of a convolution of the ileum near the abdominal ring. The intestines were generally hyperæmic, and were distended by what proved to be, on puncture, large quantities of fluid of the same character as that vomited. There was no complete constriction of any part of the intestinal canal. The peritoneum appeared healthy.

This case is curious from the enormous quantity of fluid secreted by the intestines in a short time. It appeared that the death was due to a continuous stream of fluid issuing from the pharynx during attempts at inspiration, and, in fact, *drowning* the patient. This view is supported by the *post mortem* appearances of the lungs.

CASE II.—William Johnson, aged 36, admitted March 27th, 1873, had had left inguinal hernia for eight years, and had worn a truss. The truss broke the day before admission, and the hernia became strangulated. Mr. Nankivell operated, opening the sac. Vomiting continued to a slight extent until death on March 28th.

POST MORTEM EXAMINATION, twelve hours after death.—Rigor mortis was well marked. On dissecting the anterior wall of the abdomen and examining the lower part, there was found an epiplocele of the right side. On the left side, the hernia had been returned from the canal; but a small piece of intestine had insinuated itself into a pouch formed by the division of the internal oblique and transversalis muscles, and was here constricted without showing any external signs, owing to the patient's obesity.

In this case, the corpulence of the patient was the cause of death. The deposit of fat in the areolar tissue between the muscles made it more easy to separate the muscular layers, and the thickness of the subcutaneous fatty layer had prevented the diagnosis during life of the tumour caused by the knuckle of small intestine found between the muscles after death.

CASE III.—Sarah Barringer, aged 47, admitted on October 10th, 1872, suffering from inguinal hernia of the right side, which had been strangulated one day. Dr. Brown operated; but the patient did not seem relieved after the operation, and continued to suffer from sickness until death, on October 24th, *i.e.*, fourteen days from operation.

POST MORTEM EXAMINATION, twenty-one hours after death.—Rigor mortis was well marked. The abdomen only was opened. The omentum was spread evenly over the intestines, and adherent by a small point to the pubic bone. The inguinal hernia was completely reduced. The right femoral ring was occupied by a small knuckle of intestine; the end of this knuckle was ulcerated, and had given vent to fecal matter. The iliac fascia was stripped off the os pubis and ischium, forming a large pouch. Fæcal matter found in the operation abdominal wound was traced to the roof of the crural canal.

CASE IV occurred in the practice of my friend Mr. Robert R. Brown of Strood. Ann Bridger, aged 42, widow, had had a right femoral hernia for two years. This had been strangulated three days when Dr. F. J. Brown operated, returning the hernia without opening the sac. After the operation, Dr. Brown, Mr. Redmond, R.N., Mr. R. R. Brown, and myself placed our fingers in the wound, and found the crural ring clear. The patient continued vomiting, and died on the third day after the operation.

POST MORTEM EXAMINATION, twenty-two hours after death.—Rigor mortis was well marked. The hands were black and shrivelled; the body thin; the abdomen distended with flatus. There were patches of ecchymosis about the lower part of the abdomen. The wound was healthy, but without any attempt at adhesion or suppuration. The peritoneum was covered with fresh lymph near the region of operation. The intestines were much distended with flatus. Through the crural ring a knuckle of intestine seemed to project, but could not be felt from the wound of operation. On tracing it from the abdomen, it was found to have got under the iliac fascia, and into the pelvis between the fascia

and the obturator internus muscle. On withdrawing it, it was found to be congested, but with its covering peritoneum still shining and intact.

In Case III, the operation succeeded in curing the inguinal hernia; but the dissection of the femoral hernia was so instructive, that it will repay our attention, and console me for one of the most disagreeable *post mortem* examinations I ever saw.

"The end of the knuckle of intestine was ulcerated." Now, if the constriction were caused by Gimbernat's ligament, the effused matter would not have passed into the abdomen: the constriction by the ligament would have prevented the return of the crural sheath even; it would, therefore, prevent the backflow of effused fluids. But, if the constriction were at the neck of the sac, or at the mouth of the sheath, as Erichsen says it most frequently is, the effusion could pass between the crural sheath and the muscles and vessels, and under Poupart's ligament, and, anteriorly, would be directed by the fascia transversalis into the inguinal canal, and thus into the wound of operation for inguinal hernia; posteriorly, it would get under the fascia iliaca, and, if that fascia were not attached to the lum of the pelvis, then into the pelvis between the fascia and the obturator muscle. As "fecal matter, found in the abdominal operation-wound, was traced to the roof of the crural canal", and "the iliac fascia was stripped off the os pubis and ischium, forming a large pouch", and also, as in Case IV we found the strangulated intestine "under the iliac fascia and in the pelvis, between the fascia and the obturator internus muscle", I conclude we here have anatomical demonstrations made for us by pathological processes.

In the American edition of Sir A. Cooper's work on *Hernia*, at p. 224, is the record of a fatal case of femoral hernia, from which the following is extracted. "Upon cutting through the integuments of the groin, the sac and its contents were entirely gone from thence. Looking at the right groin from within the abdomen, the peritoneum was seen pushed upwards to the extent of two inches on the iliacus internus muscle; and, upon examining this part, I found the hernial sac included in its fascial covering, and containing the intestines strangulated by a stricture at the neck of the sac, and by the fascia covering it." Again, at p. 222 of the same work, in a footnote by Aston Key, is another case of femoral hernia, fatal after operation, from which I will extract what bears on our cases. "On looking into the sac from the wound in the thigh, no intestine was at first perceived, but the surrounding parts being all taken out, and more perfectly examined, it was found pushed up between the peritoneum and the sheath of the femoral vessels." Looking at this last case by the light thrown on the subject by our two cases and Sir A. Cooper's one, I would suggest that Mr. Key overlooked the fascia which covered the strangulated knuckle, and which would scarcely be noticed unless detached to such an extent as it was at least in Sir A. Cooper's case, and here it was less than in either of ours.

As to the anatomical point of the attachment of the iliac fascia to the brim of the pelvis, or otherwise, I find that Ellis and Ledwich do not give any information; Gray, Wilson, and the seventh edition of Quain, say that it is attached there; but Jones Quain, in his fourth edition says, "It is connected closely to the bone, after which it descends, lying upon the inner surface of the obturator internus muscle"; and Aston Key, in the anatomical part of Sir A. Cooper's work, says, "It blends insensibly with the fascia of the pelvis". You will see that the authorities are divided, but the description of dissections by disease I have laid before you, give a strong support to Dr. Jones Quain and to Mr. Key.

In a small strangulated hernia, with the strangulation not caused by the arch, it would be no difficult matter to return the tumour to the abdomen, by dividing Gimbernat's ligament, and thereby giving room for the hernia to pass bodily through; but, as the peritoneum would be carried forcibly upwards at the level of the neck of the sac, it would be thereby stripped from the inside of the abdominal walls, and if it had, by pressure of the hernia, become attached to the fascia in its neighbourhood, or if the constriction were by the mouth of the sheath, it would carry the fascia with it; even in the healthy subject it is easier to separate the fascia from the muscles than the peritoneum from the fascia.

Sir A. Cooper's cases are related to show the necessity of making sure that the stricture is divided before the tumour is reduced; but, in his case, the error was made of mistaking the fascia propria for the sac; and, as such a mistake may occur again, I would suggest that, in all cases of strangulated femoral hernia, not relieved at once by the usual operation, the most frequent cause will be found to be a constriction under the iliac fascia, and this part should therefore be examined.

Finally, I would point out that, in my Case III, there was not even an attempt at reduction of the femoral hernia, so there was no force used, except such as the effusion of fluids might produce. The intestine was ulcerated through, the effused matter found its way by ulcer-

ation through the peritoneal sac, and separated the fasciae as described; but, since the force of an effusion seeking to escape cannot be very great, we must be more careful in applying even a slight force for the reduction by taxis of a strangulated femoral hernia.

CASE OF DIABETES MELLITUS TREATED BY THE SOLE ADMINISTRATION OF SKIMMED MILK: DEATH.

By HORACE CHALDECOTT, M.R.C.S. Eng., Dorking.

E. T., a labourer, was admitted into the Dorking Cottage Hospital, under my care, November 12th, 1874. On admission, he had a very dry tongue, great thirst, and hunger. The urine was of a pale greenish colour, of specific gravity 1032; on boiling with an equal quantity of liquor potassæ, it became of the colour of brown sherry. There was no albumen. The history obtained was that he had been emaciating for a few weeks, with increasing hunger and thirst, together with a progressive increase in the amount of urine passed.

I give below a table showing the amount of urine passed every twenty-four hours, and the specific gravity daily.

He was put on full meat diet, with greens, "diabetic biscuits", and plenty of milk; he was also ordered the following prescription:

R Liquor strychniæ ℥v; tinctura ferri perchloridi ℥x; aquæ ad ℥i. M. Fiat haustus ter die sumendus.

This treatment was continued until December 10th, when he was ordered eight quarts of skimmed milk daily; nothing else either to eat or drink. On December 3rd, his weight was 9 stone 5 lbs.; on December 10th, 9 stone 1½ lbs.; on December 18th, 9 stone 3½ lbs. Hunger left him after commencing the milk-diet. The bowels, which had previously been costive, were now moved copiously and regularly. He had heard from a visitor of the efficacy of the skimmed milk treatment, and was very sanguine that it would cure him.

The treatment was steadily adhered to, and the patient was apparently doing well until December 24th, when he was attacked with purging and vomiting. He also became somewhat drowsy; but this symptom was attributed at the time to the opium in the following mixture prescribed for him at the outset of the attack, of which he took six doses at varying intervals in about thirty-six hours.

R Tinctura opii ʒj; bismuthi oxidi ʒj; pulveris gummi tragacanthæ, ʒj; aquæ ad ʒvii. M. Two tablespoonfuls for a dose.

On December 25th, the purging and vomiting were allayed; the drowsiness was increasing.

On December 28th, at 9 A.M., the drowsiness had been steadily increasing, and he was now incapable of being aroused. His breathing was stertorous. The pupils were equal, rather contracted. The bowels were not relieved on the previous nor this day. The urine contained phosphates; no albumen. The patient died the same night at twenty minutes to twelve. There were no symptoms or signs of phthisis throughout. No necropsy was made.

OBSTETRIC MEMORANDA.

FETAL MALFORMATION.

A HEALTHY woman, aged 24, was taken in labour with her first child, at her full term, on August 16th, 1874. As the head, which presented, became impacted on the pubes, the forceps were used. The fetus when born showed the following peculiarities of development. The left elbow, as was also the left knee, was somewhat ankylosed. The thorax appeared natural, but the abdomen and its contents were greatly different. No abdominal walls were visible, but the viscera were only enveloped by a thin membrane, which in front and above was continuous with the skin of the thorax, a line of demarcation being well marked, and posteriorly was attached at some places to the bones, and at others was

continuous with the skin there. This membrane was without doubt ruptured during the act of parturition; the umbilicus, as innominatum of the right side, sacrum, and anus were all absent, as were the whole of the urinary tract and the pancreas. Only part of the genital organs were present, but they were not sufficiently well marked to determine the sex. The rectum terminated in the cord, which passed through the membrane about the usual position of the umbilicus; the left foot was deformed, talipes equino-varus being noticed. The fetus, though without doubt alive at the commencement of the labour, was still-born; it weighed, six hours after birth, four pounds nine and a half ounces. The drawing gives a good idea of the appearance presented by this unnaturally developed fetus. The mother states that she received a fright whilst pregnant.

W. H. SHEEHY, L.R.C.P., Claremont Square.

DOUBLE ARM-PRESENTATION.

I AM afraid that cases of double arm-presentation are not so rare as Mr. Karkeek supposes. I can report a case which occurred in my own practice about two months ago, and which ended fatally, but still worth reporting.

On the evening of December 16th last, I was sent for by two other medical gentlemen, who were in attendance on Mrs. M., as her case was an exceedingly peculiar one. When I arrived, I found both hands protruding beyond the vulva. Both gentlemen had tried to turn, but neither could introduce his hand far enough to catch a foot, owing to the jamming up of the pelvic cavity, nor could the arms of the child be put back. The pains had been very severe for eight or ten hours, and the arms were driven down this length before the regular medical attendant saw the case. Within the last hour, the woman's pulse had become very rapid, and she had the appearance of sinking. Without attempting to turn, I administered chloroform, and then tried it, but it

was quite impossible to introduce the hand, and still impossible to put back the arms. There was no alternative now but amputate one of the arms, which we did. After this was done, it was with the greatest difficulty I managed to turn. The woman died in about fifteen minutes after delivery. No *post mortem* examination was made, but I am of opinion that rupture of the uterus had taken place, which accounted for the sudden cessation of the pains, the high pulse, and the sinking appearance of the woman. I have turned in nearly all sorts of presentations, but this one presented difficulties which no one can think of until he has actually had a case. It is a pity that none of our obstetric writers say anything about this sort of presentation, as I feel certain that it frequently occurs.

There can be no doubt that if the case be seen early, there will not be so much difficulty in turning; or if one arm be quite down, and the other only partially so, then the usual method of bringing down the opposite leg to that arm which is advanced will cause the turning to be much more easily accomplished. But when both arms are driven beyond the vulva there is not only the difficulty of introducing the hand and causing the child to rotate on its axis, but the nates of the child rise and the feet are turned up behind the nates; so that, upon securing a foot, it is necessary to sweep it well backwards, for, if it be pulled straight down, the whole child becomes hopelessly jammed in the pelvis, and this was the difficulty with which I had to deal.

A. MILROY, L.F.P.S., Eglington Iron Works.

THERAPEUTIC MEMORANDA.

JADORANDI.

ON January 26th, I had a specimen of jaborandi given to me by Mr. Holloway of Castle Street, consisting only of the leaves of a plant. An average-sized leaf picked out of the specimen had the following characteristics. It was about $1\frac{1}{2}$ inch long and half an inch broad, of an ovato-oblong form, petiolate, with an oblique base, an obtuse emarginated apex and entire margin. The under surface of the leaf was hirsute, the hairs being small, few in number, and not easily recognised without a lens; but they were more numerous along each side of the midrib. The venation was reticulate; the primary veins coming off from the midrib at an average angle of 53 degs. on the side which had the larger half of the base, and at 56 degs. on the opposite side. These terminated within the margin by joining one another by means of inter-marginal branches. When held up to the light, the leaves were seen to be numerous dotted with small puncta, which were generally scattered over the surface, and appeared of a light yellow colour. The leaves have a faint odour when cold, which becomes stronger on warming.

On the evening of February 2nd, I made an infusion of thirty grains of the leaves; but, being prevented from taking it then, I took it at 12.15 A.M. the following night, swallowing both drugs and infusion. Previously, I had taken my temperature and observed my pulse and respirations. I then sat down in an arm-chair with the paper, to divert my attention from the experiment. The following table gives the variation of temperature (centigrade scale).

	Temp. in right axilla.	Temp. in left axilla.	Average temp.	Pulse.	Resp.
12.15 A.M.	35.3	35.1	35.2	60	16
12.30 A.M.	36.	36.	36.	66	16
12.45 A.M.	36.	35.4	35.7	66	14
1 A.M.	35.4	35.3	35.35	68	15
1.15 A.M.	35.35	35.27	35.31	71	15
1.30 A.M.	35.3	35.	35.15	74	15
1.45 A.M.	35.35	35.2	35.275	75	16
2 A.M.	35.35	35.3	35.325	76	16
2.15 A.M.	35.4	35.3	35.35	74	14

The pulse and respiration were taken every quarter of an hour for two hours. During the second quarter of an hour, I began to feel my saliva being secreted more freely than natural. This continued to increase in quantity for an hour and a half, but had reached its maximum before 2.30, by which time I had expectorated four ounces, being the total amount excreted. The drug with me had no diaphoretic action, and not the slightest effect upon my sight or pupils; probably because I had not taken sufficient. It will be noticed from the table that my pulse rose gradually up to two o'clock, at which time the amount of saliva secreted seemed to be diminishing. The temperature was taken by means of two Casella's registering thermometers, Nos. 17,401 and 17,402; the last mentioned registering .05 of a degree higher than the other. It was this I used for the right axilla. One thermometer was placed in each axilla, and, after every observation, the index was shaken down, and in five minutes returned to the axilla, so that it re-

mained ten minutes in position each time. From 12.15 to 9 A.M., I secreted twenty-one ounces of urine, of specific gravity 1020, of acid reaction, with no albumen. The drug appears to have no diuretic action.—ROBERT CORY, M.B., Carlisle.

MACKAY'S OMPHALIC MUSTARD PLASTERS.

I AM glad to read in the JOURNAL of January 23rd, under the heading of New Inventions, a description of Dr. Mackay's omphalic mustard leaflets. After using them frequently, I can testify to their efficacy as a most useful and elegant means for counterirritation. They can be applied with ease and accuracy, and they are free from the discomfort which generally attends the use of mustard poultices or plasters. Each leaflet is about four inches square, and contains from twenty to twenty-four discs or spots of mustard of the size of a large wafer, and they are placed so as to allow a considerable interspace between the discs. By this arrangement, two-thirds of the whole leaf are covered by the irritant, leaving the remaining third free. When used, the leaf is to be first dipped into water. The surplus water may be removed by shaking. It is then to be placed firmly and evenly upon the surface of the skin. In a few minutes, it produces a warm and not disagreeable feeling, and the skin beneath the spots becomes reddened. If allowed to remain for thirty or forty minutes, the whole surface beneath the plaster becomes affected, producing the benefit of an ordinary mustard application, but with the smallest possible injury to the skin. When the leaf is removed, the skin between the spots rapidly resumes its normal condition and appearance, whilst the impression from the discs will remain for some days. Any number of the spots may be applied, according to the effect desired; and they can be repeated upon the same surface at shorter intervals than is possible when using any other form of mustard irritant. In neuralgia, one or two spots of the mustard, placed over a painful spot along the course of the nerve, will frequently relieve the pain, with but little or no discomfort.

Upon the same principle, Dr. Mackay has produced leaflets composed of Spanish fly. The discs of the vesicant upon each leaf are smaller and more numerous than those of the mustard on the mustard-leaves; the idea being in each to imitate as much as possible the operations of nature, when relieved by the eruption of a number of papules or vesicles.

W. HEATH STRANGE, M.D.

SURGICAL MEMORANDA.

THE NEW OPTOMETER.

IF Mr. Jeaffreson will again read the description of the optometer in the JOURNAL of January 16th, he will there find that in "the beginning of 1873" I had proposed an instrument corresponding to the "Refraction Ophthalmoscope," described in his *Aids to Ophthalmic Diagnosis*, published in July, 1874, and which seems to me more completely and better fitted for the purposes for which both instruments were designed, in that while the powers obtained are more numerous, the obtaining of them by means of the rack moving the two discs is much easier. A description of the instrument will be found in a pamphlet, entitled *A Contribution to Ophthalmoscopy*, published by me in February 1873, and in the Catalogue of the British Medical Association of the same year, No. 410, p. 119. By means of this instrument, the ophthalmoscopist, or anyone accustomed to the use of optical instruments, can determine his own degree of myopia or hypermetropia, or that of an educated and careful observer. But, as in the determining of patients in private or in hospital practice, we have not generally to deal with such, and, as this instrument, by no yet known method, will enable us to correct an astigmatic ametropia, so as to allow of the determination of the refraction by the usual control tests, I cannot see how Mr. Jeaffreson can call the instrument described by him in 1874, and by myself in 1873, the same instrument as one in which, by the combination of + and - spherical and cylindrical lenses, arrangements are made for the determination of simple, compound, or mixed astigmatism, in addition to the simple myopia and hypermetropia corrected by the instruments abovementioned.

The objections which Mr. Jeaffreson found to his instrument from its size and the necessity of having recourse to the table of calculations, were foreseen and obviated in the new instrument proposed, by having the glasses of the usual testing size, and by the product of any combination being found opposite the combination.

The table of calculations had been formed by me on much the same plan as Mr. Jeaffreson's, but occupying half the space. It will be noted that the one-half of the calculations in Mr. Jeaffreson's table is a repetition of the other, which a slightly different arrangement of the figures would have rendered unnecessary.

W. LAIDLAW PURVES, Hanover Street.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

GUY'S HOSPITAL.

ANEURISM OF INTRAPERICARDIAL PART OF AORTA: EMBOLISM OF FEMORAL ARTERY: GANGRENE OF FOOT AND LEG: AMPUTATION OF THIGH: DEATH: NECROPSY.

(Under the care of Mr. BIRKETT.)

FREDERICK S., aged 33, an engine-driver, was admitted into the Hospital on June 15th, 1873. He gave a good family history. His own ailments had been limited to a sore on the penis contracted fourteen years previously, and followed by a bubo; to a "bad sore-throat" five years ago; and to indigestion. His usual daily allowance of beer had been four pints; and he had occasionally been intoxicated. Eight days before admission (June 7th), he had become suddenly faint, and fallen insensible; but had soon recovered. An hour afterwards, however, great pain had commenced in the right leg, and the patient could not stand upon it. The pain continued; and, on June 10th, the toes had begun to turn black. The blackness had slowly extended up the limb; and, on June 14th, there was some swelling of the right arm.

On admission, the right foot and adjoining part of the leg were gangrenous. Behind, and at the sides, the gangrene extended over the lower two-thirds of the limb; in front, it reached halfway up only. The skin on the dorsum of the foot was of a dark red colour; on the sole, it was nearly black, and the superficial veins were full of blood; on the leg, the skin was livid, and presented blebs containing a sanguineous fluid. The gangrenous part was quite insensible to the touch; but the skin of the limb immediately above it was inflamed, and exceedingly tender and painful. There was occasional pain in the foot. The dead part was not moist, and no odour arose from it. The man felt very weak; had no appetite; and the pain prevented sleep at night. The tongue was coated with a brown fur; the bowels were confined; the urine contained no albumen; the liver was enlarged. The sounds of the heart were feeble and intermittent; there was no *bruit*. The apex-beat was not perceptible. There was an unusual extent of dulness behind the sternum. Pulse, 120; respirations, 20; temperature, 99.5 deg. He was ordered

Liq. morph. hydrochl. ℞; acidi hydrochlor. dil. ℞; decoct. cinch. flav. ʒj, every six hours. Beer, two pints daily.

June 17th. He had not slept during the night; he complained of a pricking sensation in the sole of the foot. Pulse, 120; temperature, 99 deg.

June 18th. The patient had slept after a subcutaneous injection of morphia administered the previous evening. He had lost the power of extending his right hand; and could only partially use the fingers of that side. There was a little pain in the same wrist. Pulse, 120; temperature, 99.4 deg.

June 19th. He had slept again after an injection of morphia, and had regained the power of extending his right hand. The gangrene had not advanced up the leg; and the inflamed skin above the line of demarcation was rather less painful. Pulse, 120; temperature, 99 deg.

June 20th. Although morphia had been injected the previous evening, the man had passed a restless night. The leg was beginning to smell badly. Pulse, 120; temperature, 99 deg.

June 21st. He had again slept badly after an injection of morphia. Pain in the leg had increased. Pulse, 120; temperature, 101.4 deg. He was ordered pil. opii gr. i, to be taken twice a day; and to continue the mixture ordered on the 16th.

June 23rd. He had passed a better night. The bowels had not been opened for four days. The tongue was dry and brown. Pulse, 120; temperature, 101.8 deg. He had headache, and severe pain in the leg. There had been some swelling of the right side of the head and neck. He did not talk quite rationally. The gangrene was more complete, but had not extended higher up the limb. The superficial veins of the thigh looked turgid.

4 P.M. Mr. Birkett determined to amputate the limb. Upon chloroform being administered, the patient took it badly, and had several attacks of threatened apnea. The femoral artery was compressed by a weight. Mr. Birkett made lateral semicircular flaps in the lower third of the thigh. Torsion was used on the femoral artery and several smaller vessels; the flaps were united by six interrupted sutures; the stump was then wrapped in carbolic gauze, and placed on a splint.

The disorganisation of the tissues of the foot and leg was too far advanced to allow any changes in them to be usefully recorded.

June 24th. He had passed a very restless night. At 8 A.M., paroxysmal attacks of dyspnoea commenced, which much resembled epileptic convulsions, but were not accompanied by lividity of countenance. The pulse became very quick, but was not irregular; and, at the onset of the convulsion, the patient was sensible. As the fit progressed, temporary coma supervened, from which he slowly recovered with a sighing respiration. There was much pain over the mid-sternal region. In one of the above noticed paroxysmal attacks, he died at about 11 A.M.

An examination of the body was made on June 25th. The heart weighed ten ounces. The pericardium was greatly enlarged. It contained thirty-two ounces of a bloody fluid, which was not coagulated, and was evidently a mixture of blood and serum. The parietal layer of the pericardium was roughened by lymph. The visceral layer was covered by a thin, but coherent, lamina of lymph, and in places this was separated from the heart's surface by a layer of coagulated blood, especially over the posterior surface of the right ventricle, where this layer of blood was more than a quarter of an inch thick. Beneath it, and immediately in contact with the heart itself, was a layer of inflammatory material. It was, therefore, evident that the pericarditis had existed before the escape of blood into the pericardial sac; that the blood had entered beneath the layer of lymph just formed on the visceral membrane, and dissected this off; and that afterwards a fresh layer of lymph had formed beneath the blood. The heart-substance and valves were healthy. In the right side of the base of the aorta, about half an inch to an inch above the valves, was an opening (of about the size of a florin) into an aneurism about as large as a billiard-ball. This aneurism came forwards to the right side of the base of the pulmonary artery; it projected as a rounded tumour beneath the endocardium lining the right auricle; and the superior vena cava was also stretched over it. Where it projected into the pericardial sac, it was very thin; and an oblique rent existed, which was probably very small before it had been disturbed. There were some adhesions of the pericardial layers over the aneurism. The aneurism contained chiefly soft black coagulum; but the surface of this which looked towards the interior of the aorta was firm, buff-coloured, resembled chamois-leather in appearance, and had a smooth curved surface, as if it were part of a solid ball of fibrine. The aneurism extended upwards for some little distance outside the aorta, between it and the superior cava. Just below the origin of the innominate artery, there was a rough depression on the wall of the aorta, about as large as a sixpenny-piece, having some rough lymph adherent to it. The aneurism lay just outside this; but no communication could be traced. The femoral artery was plugged, just below the origin of the profunda, by a mass of disintegrating adherent fibrin of a brown colour; it occupied a part of the artery about an inch in length. The liver was healthy. The lungs contained some oedema. The spleen weighed seven ounces; in some parts it was much blacker than at others, but was of the same consistence throughout. It could not be made out that it contained embolic patches. The kidneys weighed fifteen ounces; they presented several irregular embolic patches, some of considerable size, partly pale yellow, partly crimson from effused blood. The smaller arteries were searched with care, but no coagula could be discovered.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.

EPITHELIOMA OF THE TONGUE: DEATH FROM CHLOROFORM.

(Under the care of Mr. ARTHUR JACKSON.)

H. J., AGED 56, admitted January 5th, 1875, had suffered from epithelioma of the tongue for two and a half years. The tongue was very painful and enlarged, and increased in size from the time of his admission, so as seriously to interfere with mastication. During the last three weeks, he was only able to take liquid food; and his troubles had so much increased that he willingly consented to have the whole of his tongue removed. It was decided to do this with the galvanic extirpator. The heart and lungs were carefully examined, and found to be healthy; the pulse was feeble, but fair; the urine was normal. On February 19th, chloroform was administered on lint, with a view to operation. A few minutes after the commencement of the inhalation, the pulse became slightly intermittent, but soon regained its tone. As the patient struggled a great deal, the administration was continued with increased caution. After the lapse of about ten minutes, the patient appeared ready for operation, and one needle was passed into the tongue; but it had to be withdrawn at once, as, without any stertorous breathing, failure of the pulse, or blanching of the face, the respiration became irregular and ceased, but not before the chloroform had been discon-

tinued, and artificial respiration had been commenced, together with the application of cold to the chest, ammonia to the nose, and the galvanic current to the diaphragm. These remedies, with nutrient enemata, were continued for half an hour. The pupils were dilated. The heart continued to beat for some little time after the cessation of respiration. Three drachms of chloroform were administered.

Autopsy.—Seventy-eight hours after death. The brain and heart were healthy; the left ventricle was contracted, the right relaxed, but neither contained clots. The blood throughout the body was black and liquid. The lungs were healthy, not much engorged with blood; but both pleurae were adherent to the thorax and diaphragm. The trachea and bronchi contained a large quantity of grumous mucus. The stomach was distended with air, which had a strong odour of chloroform. This was not perceived in any other part of the body. The liver and kidneys were healthy.

The whole of the disease in the tongue could have been removed without much difficulty. Death in this case appeared to have resulted from paralysis of the nervous centres of respiration.

REVIEWS AND NOTICES.

THE WEST RIDING LUNATIC ASYLUM MEDICAL REPORTS. Edited by J. CRICHTON BROWNE, M.D., F.R.S.E. Vol. iv. London: Smith, Elder and Co. 1874.

The fourth volume of Reports, which has lately been published by the Superintendent of the West Riding Asylum, is in no respect inferior to its predecessors. Of the twelve papers contained therein, seven are by officers of the asylum, chiefly upon subjects connected with insanity, while the remainder are by physicians of note, upon brain-function or brain-disease.

The now well-known experiments of Dr. Ferrier were, as most of our readers are aware, performed at the West Riding Asylum, and described in the third volume of these Reports. The first paper in the present volume is an address delivered by Dr. Carpenter at the asylum upon the physiological import of Dr. Ferrier's investigations. The latter are now so well known that we need not dwell on them here, or on Dr. Carpenter's views of them. The third paper is one by Dr. Ferrier himself, who applies the clinical bearings of his researches to certain cases of patients, as narrated in the case-books of the asylum. The first two were cases of epileptic insanity; in both were found lesions of the cortical structure of the hemispheres. Dr. Ferrier discusses the question, whether convulsive discharges proceed from the lower centres, as the medulla, or from the cerebral hemispheres themselves, and reminds us that his experiments on the lower animals showed that convulsive attacks, with all the phenomena of idiopathic epilepsy, can be caused by irritation of the surface of the hemispheres in certain places, while there are other parts, stimulation of which gives rise to no external phenomena whatever. Case 3 was an example of cerebral tumour. Case 4 was one of aphasia complicated by dementia. There was extensive atrophy of the region supplied by the anterior cerebral artery, and on this the dementia evidently depended; there was also destructive lesion of the left hemisphere. Dr. Ferrier would localise the speech-centre in the *operculum* (Klappeckel), which is included between the ascending and horizontal limbs of the fissure of Sylvius, and which immediately overlaps the island of Reil. Case 5 was one of melancholia with lesions of both hemispheres, especially the right, producing loss of power. Various motor centres were involved, those of the hand and mouth especially; and not only motor centres, but also sensory regions of the brain. The occipital lobes, too, were involved. When these were destroyed in a monkey, Dr. Ferrier observed a remarkable state of depression, with refusal of food, such as one finds in melancholies, and he raises the question whether the melancholia in this woman depended on the lesion of these parts, or on the general malnutrition of the brain.

In the paper by Dr. Milner Fothergill on Cerebral Anæmia, in those of Drs. Crichton Browne and Aldridge on Acute Dementia, and the Ophthalmoscopic Observation of it; and, to some extent, in that of Dr. Lauder Brunton on Inhibition, the attention of the reader is directed to that all-important question, the blood-supply of the brain, and the causes which interfere with its healthy function. We have been ever of opinion that, by this line of investigation, the most important results will be arrived at with regard to the pathology and treatment of insanity, and no publications have done more in this direction than the present series of Reports. For it is by the effect produced on the circulation in the brain, that such substances as ergot, Calabar bean, and nitrite of amyl, are of value; and both pathological observation and the results of drug treatment agree and lead us on to fresh

inquiries. It has been a fashion with some inquirers to fix their attention exclusively on the brain-cells, and to ignore the circulation in the organ and the nervous system which governs it; but on the rise and fall of the circulation the healthy action of the organ must depend; and this is shown more clearly, day by day, by physiology, pathology, and therapeutics. Dr. Fothergill reminds us of the peculiar mental changes undergone by the sufferer from advanced heart-disease, which, he says, go far to establish the conclusion that the vascular changes are not always the result of primitive changes in the brain-cells affecting the blood-supply as a secondary action, but that modifications in the vascular supply to the pia mater and grey matter of the convolutions, do exert a consequential action upon the functional working of the cerebral cells, and the thoughts evolved therefrom. When no muscular hypertrophy accompanies and compensates organic disease of the heart, the mental condition of the individual often becomes distinctly altered. Self-reliance and confidence give way to distrust and suspicion. Sustained thought is no longer possible, and mental irritability alternates with depression. The conditions under which cerebral anaemia is found, are enumerated as 1, general anaemia, proceeding from such causes as piles, menorrhagia, lactation, and the like; 2, spasmia from blood-poisons, malaria, or acute diseases; 3, unfilled vessels; 4, disease of the heart; 5, pressure on the arteries supplying the brain; 6, embolism; 7, venous stasis; 8, apoplexy, and other forms of pressure; 9, gouty spasm of the cerebral vessels; 10, organic disease, as syphilis, involving the blood-vessels; 11, vaso-motor disturbances of the cerebral vessels; 12, artificial production by medicinal agents, as Calabar bean and bromide of potassium. Cerebral anaemia is divisible into acute and chronic, the signs of the latter being the condition of the pupil, which is generally dilated, pallor of the face and eye, and of the optic discs; the general state of the circulation, cold hands, drowsiness, and headache, are also to be noticed, and we may also find vomiting, palpitation, sighing respiration, and constipation. In treating such cases, Dr. Fothergill gives the first place to iron, opium, and alcohol.

We have not space to give an accurate analysis of Dr. Lauder Brunton's interesting and suggestive paper on Inhibition, that difficult subject, which at present occupies much of the attention of physiologists. The effects of it on muscles, glands, and vessels, will have to be considered again and again before any definite conclusions can be arrived at. Not only must we investigate what causes inhibition: it is equally important to discover what prevents it, what inhibits inhibition. "At present, our notions of nervous action seem to be getting as involved as the Ptolemaic system of astronomy; and, just as epicycles become heaped upon cycles, so nerve-centres are being added to nerve-centres; and yet, clumsy though the system may be, it serves at present an useful purpose, and may give us real aid until a better is discovered." Dr. Brunton suggests that inhibition in the higher centres may be explained by diversion of stimuli, without assuming the existence in them of an inhibitory apparatus, such as we have in the lower ones. A stimulus may excite action in a nerve-centre which may pass off partly in motion, partly in secretion, partly in vascular change, and partly in alteration of the nervous system. And the oftener it passes along any nervous path, the more readily does it find its way along that in preference to any other. Hence we see the importance of diverting the insane, who suffer from emotional disturbance, by exercise and muscular action, which will benefit not only the mental but also the visceral condition. The emotional centres, too, are inhibited by the ideational, and the conflict between these is witnessed in lunatics who request to be restrained and prevented from suicide or homicide, and in those who are powerless to abstain from alcohol, which they know to be their ruin.

Dr. Major continues his observations on the Morbid Histology of the Brain, and in this volume presents us with the result of his examination of brains in a state of Senile Atrophy. His conclusions are, that the brain cells throughout the entire depth of the cortical layer are affected, the larger ones being usually in a state of granular degeneration, the smaller simply atrophied; that the nuclei of the cells participate, and also become the seat of granular degeneration; that the so-called hypertrophy of the cells depends on a transformation of the large pyramidal bodies, and is not confined to senile atrophy, being also found in general paralysis, and rarely in either. The vessels were most frequently dilated with enlargement of the vascular canals. The fibres were abnormally coarse and tortuous, and appeared broken down in parts; the neuroglia was atrophied and degenerate, the substance breaking down into molecular debris; the neuroglia-corpuscles were somewhat increased in number, and eventually shrunken and atrophied.

Dr. Crichton Browne contributes a paper on Acute Dementia, which he ascribes to inanition of body combined with inanition of mind, the monotony of mill-life or life in prison. The disorder and its mental phenomena are described with accuracy, especially the

automatic and rhythmical movements so often witnessed. M. Baillarger described this disease as *melancholia attonita*, which Dr. Browne renders atonic. The remarks on the diagnosis of the two disorders are instructive, but we must demur to the assertion that acute dementia most often arises out of physical causes. In our experience, the exciting cause has been most frequently a mental shock or fright, joined, it may be, to the effects of previous physical depression or starvation. The state of the brain in this disease is, according to Dr. Browne, one of cerebral congestion from vascular weakness; atony and increased califure of the capillaries and veins are established, either by constitutional weakness or by nervous exhaustion, and are followed by retardation of the blood-current; the removal of the products of combustion from the brain is retarded, and the functional activity of the organ is interfered with. Oedema occurs, then compression, then atrophy, and so acute dementia passes into chronic. These views receive confirmation from the ophthalmoscopic observations of Dr. Aldridge, who discovered marked anaemia of the disc and occasionally oedema; the arteries were small, shrunken, and straight, and the veins dark.

Those interested in ophthalmoscopic research will find a paper by Dr. Hughlings Jackson on a Case of Recovery from Double Optic Neuritis. Dr. Morson contributes Observations on the Urine of Patients suffering from General Paralysis while taking Calabar bean and alcohol, and also while under no medical treatment. Dr. Benham writes on the Therapeutic Value of Cold to the Head, which he believes to be small. Other papers are, Dr. Robert Lawson's on the Hourly Distribution of Mortality, and Dr. Benham's on the Actions of Nicotine.

SELECTIONS FROM JOURNALS.

MEDICINE.

CHOREA AFTER DIPHtheria.—Dr. Baumblatt describes in the *Aerztliches Intelligenz-Blatt*, No. 25, 1874, the case of Maria D., aged 21, who, after a mild attack of diphtheria, had choreic paroxysms which set in suddenly, lasted three or four minutes, without loss of consciousness, and ended as suddenly as they had begun. Indications of a high degree of chloenosis gradually appeared; the menses became scanty and rare, and she was extremely anaemic. She was treated by iron and morphia, also by an energetic use of the cold-water system. At the end of two months, she was sent to the iron-springs at Boklet, and returned in six months much improved in her general health. The chorea, however, continued, and did not disappear until she had made a second visit to Boklet in the following year; since which, four years ago, there has been no return of the malady.

TREATMENT OF SCABIES.—Dr. F. W. Clemens of Rudolstadt recommends inunction with arsenic as a means of destroying the acarus of itch. The following are the proportions of the ingredients in his formula: Arsenious acid, 1 part; carbonate of potash, 20 parts; soap-spirit (soap-liniment?), 200 parts; water, 2,000 parts. Some of this is rubbed into the affected parts twice daily. The carbonate of potash increases the solubility of the arsenic, and prevents too rapid desiccation; and the soap-spirit facilitates the passage of the remedy into the cuticle. Dr. Clemens says that he has tried this treatment for five years with complete success, and without having on any occasion observed gastric disturbance or any other ill effect.—*Allgemeine Medicinische Central-Zeitung*, December 9th, 1874.

SUBCUTANEOUS INJECTION OF STRYCHNIA IN INCONTINENCE OF URINE.—Dr. Kelp, director of the lunatic asylum at Wehen near Oldenburg, describes the results of subcutaneous injection of strychnia in two cases (*Deutsches Archiv für Klin. Medicin*, Band xiv, Heft 3 and 4). One case was that of a girl aged 16, who was admitted with *melancholia stupida*, and was discharged cured at the end of about a year and a half. She was small and feeble, and had been badly cared for at home. From childhood, she had suffered from nocturnal incontinence of urine. Small doses of strychnia, given internally, produced no effect. But, after the injection of one-sixteenth of a grain of nitrate of strychnia dissolved in water (one grain in two drachms) in the sacral region, the enuresis ceased, and did not return for some days. The injections were repeated from December 17th, 1867, to April 3rd, 1868, whenever the enuresis returned; it appeared at gradually increasing intervals, and at last ceased. The dose of strychnia was increased to one-sixth of a grain. During the whole time, not more than four grains were used. For a year after her discharge, she resided near the hospital, and was occasionally troubled with incontinence of urine, which was removed by a repetition of the remedy. She has

since married, and has not come under Dr. Kelp's notice; from which he concludes that the enuresis has not returned. The second patient was an imbecile girl aged 20, who had suffered from enuresis from childhood. The treatment was the same as in the former case, and the result was as good; but Dr. Kelp does not know whether the result is permanent, as he has not heard of the patient since she left the asylum. The treatment was continued for about two years, during which about ten grains of strychnia in all were used. The intervals between the attacks of enuresis varied from some weeks to a few days. The usual dose was one-seventh or one-eighth of a grain; but, even when this was used daily, no general action on the system was observed.

CADAVERIC POISONING.—Dr. Odenius of Lund, in vol. vi of the *Årskrift Med. Arkiv*, agrees with Neumann, Hüter, and Cohnheim, that infection from the dead body may take place through the sound skin through the medium of the follicles. The sweat-glands, however, in consequence of their structure, are less favourable to this than are the others. He observed some time ago that, after making *post mortem* examinations, the hands of himself and his assistants became covered with pustules; and at length it was found that this arose from the friction of the hands with cocoa-butter, which had stood in the room for a long time and had become rancid. In 1871, he made an experiment on himself, which was troublesome, but convincing. After examining a recently dead body from pneumonia, he perceived the next day a painful swelling on the anterior surface of the forearm. There was no wound; not the slightest laceration; but at the necropsy a little fluid from the body had come into contact with the arm, and had been pressed on it by the wristband of his shirt. Sloughing of a portion of skin took place at the part. While the disorder was at its height, Dr. Odenius observed that movements of the muscles of the forearm were attended with rigors, which he attributed to the increased entrance of pyrogenous material into the lymphatic vessels. During the next year, he had several opportunities of making similar observations on himself and his assistants. He remarks that similar symptoms of poisoning are produced by attendance on difficult labours, which require long continued operations and manipulations. In any case, in order to produce the effect described, there must be a certain predisposition, a fine skin, etc., or a continued and close contact of the infective material with the cutaneous follicles.

SURGERY.

TREATMENT OF MALIGNANT LYMPHOSARCOMA BY ARSENIC.—This plan is not novel. A large number of surgeons, since Lefebure de Saint Ildefond, have used arsenic either internally or as a topical remedy for cancer; and, although the majority have not published any successful results which may be exclusively attributed to that agent, they appear to have obtained some good effects from its use. Dr. Tholen reports four cases of lymphosarcoma treated by arsenic in the practice of Professor Czerny, in one of which the administration was obliged to be relinquished in consequence of serious accidents to the sight and hearing which supervened. In another case, an enormous ganglionic tumour ceded rapidly to the administration of Fowler's solution; but a serious hæmophilic condition developed itself, which rendered it necessary to suspend the treatment. At the same time, the spleen showed an increase in size, which soon made rapid progress. In the two other cases, Fowler's solution, employed internally as well as in interstitial injections, induced a cure. One especially was at first thought to be an epithelial infiltrated cancer. The author gives expression to some doubts on the exactness of this diagnosis, and is inclined to consider it a malignant lymphosarcoma. He compares these four cases with two others already made public by Billroth, and sees in them a confirmation of the opinions which were formerly held respecting the efficacy of arsenic for cancer. As to the method of administration, he recommends the greatest reserve in the employment of Fowler's solution in interstitial injections, and proposes to reserve the latter for instances of true cancer. The lymphosarcomata would be sufficiently modified by the internal administration of arsenic. The interstitial injections, possessing much greater local activity, are not devoid of danger, as two of the cases sufficiently prove.—*Archiv für Klin. Chirurgie*, vol. xvii, fasc. 1.

THERAPEUTICS.

ACTION OF EXTERNAL APPLICATION OF WATER, ETC., ON THE CEREBRAL BLOOD-VESSELS.—Schüller of Laubach has made a number of experiments on rabbits to ascertain the effect on the cerebral vessels of the external application of warm and cold water, etc. His

paper is published in the *Corresp.-Blatt der ärztl. Vereine in Rheinland, Westphalen, und Lothringen*, No. 14, 1874. The animals were trephined, and in course of time the cervical sympathetic on one side was removed. Some of them were curarised. The following were the results which he obtained. 1. Dilatation of the vessels of the pia mater is produced by laying compresses soaked in water at a temperature of 50 Fahr. on the abdomen, and in a more intense degree and of longer duration by immersing the animal in the water. If the action of the cold water be continued for five or ten minutes, the result is gradual contraction of the cerebral vessels, which often lasts half an hour. 2. The application of warm water (95 to 99.5 Fahr.) always produces strong contraction of the vessels, which lasts for a longer or shorter time. 3. Douches on the belly or back generally produce alternating changes in the calibre of the cerebral vessels. 4. The injection of water into the rectum is attended with moderate dilatation of the vessels. 5. The usual result of the cold pack is a gradually increasing and very energetic contraction of the vessels of the pia mater, which often lasts two hours. At the same time, the pulse and respiration become slower, and reflex irritability is reduced. 6. Ice laid on the intact skin of the head produces after some time a moderate contraction of the vessels. 7. Friction of the abdomen always produces contraction. The results were observed in curarised animals in a less marked degree than in those not so prepared. Section of the vagi has no influence on the changes in the vessels. Schüller makes some further remarks of physiological interest; and, with regard to the practical part of the subject, observes that the use of extreme temperatures is contraindicated in cases of cerebral hyperæmia, anæmia, and congestion, especially where the muscular structure of the blood-vessels is impaired. He attributes the beneficial influence of the various forms of baths partly to the depletion of the cerebral vessels, partly to the establishment of normal tone in the muscular structure of the cerebral vessels, to strengthening of the cardiac muscle, and to improved nutrition both of the nervous centres and of the whole organism. The chief point of interest in Schüller's communication is, that the action of baths is not limited to the temperature and the change of substance, but that changes in the distribution of the blood, in respiration, in the action of the heart, and in excitability of the nerves, form part of the physiological results of this agent.—*Allgemeine Medicin. Central-Zeitung*, No. 94, 1874.

ACTION OF CERTAIN MEDICINES ON THE VESSELS OF THE BRAIN.—Schüller (*Berliner Klinische Wochenschrift*, Nos. 25 and 26, 1874) performed experiments on rabbits by removing, with a trephine, a portion of the upper part of the parietal bone without injuring the dura mater, and generally at the same time taking away the cervical sympathetic with the superior cervical ganglion of the same side. He was thus able to observe the vessels of the pia mater, and to notice any changes in their filling. The substances with which he experimented were mustard, nitrite of amyl, ergotin, opium, and chloroform. Small sinapisms produced scarcely any effect on the vessels; the application of large ones, on the one hand, was first regularly followed by dilatation, which was followed by more or less rapidly alternating changes in the calibre of the vessels, and finally by contraction, which often continued an hour and a half after the removal of the sinapism. To explain these phenomena, Schüller supposes that at first the irritation of the sensory cutaneous nerves produces, by reflex action, a partial paralysis of the vaso-motor nerve-fibres (dilatation), and that later on the influence of the peripheral congestion exerts its influence and ultimately gains the upper hand (oscillations of calibre and contraction).—After nitrite of amyl, there was a very evident dilatation of the vessels of the pia mater, both arteries and veins. It could be observed even on the side where the sympathetic had been injured, and where there was already dilatation of the vessels; and took place both after section of the vagus and in curarised animals. This action, according to Schüller, depends on the degree of filling of the vessels, and the capability for reaction of their muscular structure. Ergotin produced a strong and long-continued contraction of the vessels of the pia mater, even on the side where the sympathetic was injured. Schüller regards ergotin as standing in a certain antagonistic relation to nitrite of amyl, inasmuch as the contracting action of the former overcomes the dilating action of the latter. Opium produced first dilatation, then contraction.—After the inhalation of chloroform, there was a commencing contraction of the vessels; but very soon they became relaxed, and well marked venous stasis was developed. Nitrite of amyl not only very quickly removed this action on the vessels of the pia mater, but, when chloroform narcosis was carried to a far more advanced stage, under the action of nitrite of amyl the laboured dyspnoic respiration and the pulse quickly recovered themselves, and in a remarkably short time reflex excitability was restored.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, FEBRUARY 27TH, 1875.

THE ARTISANS' DWELLINGS BILL.

IN our last article on this Bill, we pointed out numerous defects, and shall now state some of the amendments which we consider to be necessary for its satisfactory working.

In Clause 3, we showed that the basis on which the report of the medical officer of health is to be formed is too limited: and we therefore propose that the words contained in the preamble should be added, so as to enable him to state that an improvement-scheme is required, if the houses situated within the area be uninhabitable from want of light, air, ventilation, or of proper conveniences, or because the sanitary defects in such area cannot be otherwise remedied, in consequence of the closeness, narrowness, and bad arrangements of the streets and houses situated therein. We are also of opinion that, if there be any spaces of ground which have been, or may hereafter be, rendered vacant under the provisions of Torrens's Act, the local authority should have power to purchase the ground compulsorily, in the same manner as if it were still occupied by houses. We are also of opinion that Clause 3 should be amended by the addition of such words as would compel the local authority, in the event of their not taking action on the "official representation" of the medical officer of health within four months after receiving the representation, to forward a copy thereof to the "confirming authority", together with their reasons for not taking action.

As regards Clause 4, we think that the medical officer of health should have the assistance of a surveyor, and, in the metropolis, of the district surveyor, in coming to the conclusion (see Clause 3) "that the sanitary defects in such area cannot be effectually remedied otherwise than by an improvement-scheme for the rearrangement and reconstruction of the streets and houses", or some of them, in such area. It is manifestly unjust that "a medical officer, acting in pursuance of this Act, shall make such representation whenever he sees cause to make the same", or that he shall be compelled to inspect any area deemed unhealthy by any twenty ratepayers of the district, and make an official representation thereon, without having the assistance of a surveyor or a medical officer of the Metropolitan Board of Works, or of the Local Government Board, as the case may be. There are many places regarding which medical opinions would differ as to the necessity for reconstruction, or where the local medical officer of health, being in doubt, would not take action, unless he had the power of calling in some consulting officer of a superior Board. We, therefore, think that Section 9 should be so altered as to enable the Local Government Board for all extra-metropolitan places, and the Metropolitan Board of Works for all metropolitan places, to send a medical officer to assist the local medical officer; or, if deemed necessary, to make a special sanitary inquiry into the condition of any suspected localities. These officers should be permanently appointed, and not temporarily, as suggested by the ninth clause.

The fifth clause might be amended, as we suggested in our last, by allowing the new houses to be erected a short distance from the old area, if deemed advisable.

By Clause 6, the local authority is required to serve a notice on every owner, etc., of any lands proposed to be taken compulsorily, requiring an answer whether he assents or dissents in respect to the scheme; and it is provided that the notice may be sent by post as an ordinary prepaid letter, or served personally or at his house. Surely the sending it as an unregistered letter should not be sufficient service; and this is especially noteworthy, as by the same clause the petition from the local authority to the Secretary of State or Local Government Board shall state the names of the owners, etc., who shall dissent "in respect of the taking of their lands". What about the owners, etc., who may not have received notice, or from other cause, have not replied? Are they to be considered as affirming the scheme? Proof also is required of the serving of the notices; but it is not stated how the serving of the notices sent by post is to be proved.

Passing by some other technical objections, we notice that a provisional order made by the confirming authority, authorising the local authority to carry out the scheme, "shall not be of any validity until and unless it has been confirmed by Act of Parliament"; and, when confirmed with such modifications as shall seem fit to Parliament, it shall be deemed a public general Act. Surely there cannot be any necessity for the confirming authority to go to Parliament and put the local authority probably to the expense of a parliamentary opposition, for the sake of houses worth only a few hundred pounds. How much better would it be either that below a certain value, say £500, or when fewer than a certain number of houses were concerned, this should be unnecessary. The scheme is expensive enough without adding this burden, which may be very heavy, in addition to those previously mentioned. This clause also provides that all costs, expenses, and charges incurred by the confirming authority, or any person to whom they are allowed, shall be paid by the local authority by a given time, with interest at five per cent. per annum, should the confirming authority so determine. This power of charging interest should not be allowed, especially as the order may be made a rule of one of Her Majesty's superior courts, and be enforced accordingly.

As regards the acquisition of lands, it is proposed that the estimate of the value shall be based upon the fair market-value of the lands or interests proposed to be taken, but without additional allowance for compulsory purchase. Now this, although definite enough as regards the lands, is most indefinite as regards the other interests: as, for instance, how is the value of a term to be computed when the houses to be taken are let out in separate tenements, and bring an enormous rental, as compared with their structural value? Would it not be better to enact that the value shall be computed on the rental of other similar houses in the vicinity not underlet—subject, however, to deductions for dilapidations, etc.; or that it should be based on its structural value? It is true that, in the first and second clauses of the schedule, it is stated that the schedules of the lands forwarded by the local authority to the confirming authority "shall be accompanied with an estimate of the annual value and saleable value of such lands"; the annual value to be the amounts stated in the last valuation-list, or the gross value or estimated rental in the last poor-rate. If the fair market-value should be assessed on this basis, with a deduction for dilapidations, and not on the rental realised by subletting, an unobjectionable award might be made, especially as the word lands in the interpretation-clause is defined to include "messuages, lands, tenements, and hereditaments of any tenure".

We would propose another amendment to which we attach considerable importance; viz., that the local authority should be empowered to include property adjoining the unhealthy area, if in their opinion the possession of such property were necessary for perfecting the scheme of reconstruction. Of course, in such cases, parliamentary sanction of the plans should be obtained, unless an agreement be entered into by arrangement between the local authority and the owners and others

possessing an interest in the lands proposed to be taken. As the Bill now stands, an improvement-scheme can be compulsorily carried into effect only as regards the lands which are situated within the area declared to be unhealthy.

The provisions contained in the thirty-third clause of the schedule are, with the exception of the proposed arrangements for appeal from the decision of the arbitrator, so technically legal, that we do not propose any amendment thereon. But we must again express our opinion against an appeal from the decision of the arbitrator being carried to a jury, except for a larger sum than £500; and we would propose that the limit fixed should apply not only to the local authority as at present, but should extend to every person interested who shall be dissatisfied with the award. We also object to the local authority having to pay a sum not exceeding £20 as costs to the person appealing against the decision of the arbitrator, in the event of the verdict of the jury being for a less amount than the sum awarded by the arbitrator; and, on the contrary, would propose as an amendment, that the costs of a trial by jury, if allowed by the Act, should abide the issue of the trial, as in every ordinary case. It is true that this payment is required to be made only when the local authority is the appellant, but we do not perceive any good reason for making this distinction.

In conclusion, we must again express our opinion that the principle of the Bill is valuable, but that it is so weighed down by the cumbrous machinery and the enormous expenses to the local authority, that it will never be carried out to any extent, except by agreement, unless it be very much simplified in Committee.

JABORANDI.

THE new drug, like other new drugs, is rising into notoriety. Fortunately for its ultimate position, it has fallen, from the first, into good hands. It has not attained, at a single bound to the proud eminence of a panacea, only to sink after a few months of popularity into deserved contempt.

The leaves, introduced to the notice of the Parisian medical world by Dr. Coutinho of Pernambuco, are derived from a plant growing in Brazil; their precise origin, however, has not as yet been satisfactorily ascertained. Botanists refer them to the natural order Rutaceæ (*Pilocarpus pinnatus*, Baillon); while pharmacologists are more inclined to believe that they are derived from some Piperaceous shrub. They contain a volatile principle, and a tasteless substance, soluble in water, both of which are physiologically inert; the active properties of the drug residing exclusively in a bitter extractive, soluble in alcohol, but insoluble in water. An alkaloid was searched for by Rabuteau, but none was found.

The original reputation of the drug as a sialagogue and diaphoretic may be said to have stood the test of inquiry by competent and independent observers. Gubler, Rabuteau, and Vulpian in France; Ringer, Gould, and Martindale in this country, have furnished adequate materials for a general sketch of its action. Though differing in minor points, observers are unusually unanimous as regards the more important of the effects produced.

Shortly after the administration of a dose of sixty grains of the leaves, a copious perspiration breaks out all over the body; the face is flushed, the pulse is usually quickened from twelve to forty beats, and the temperature falls from .4 deg. to 1.4 deg., the depression lasting from one to four hours. The sweating is very constantly associated with profuse salivation—the quantity of saliva in one case amounting to twenty-seven ounces. Nausea and vomiting sometimes occur, attended by pallor and prostration, and occasionally by drowsiness. The pupils are usually contracted, and vision may be impaired. On the day of administration, the quantity of urine is said to fall considerably below the normal standard; the reduction taking place not only in the urinary water, but in the urea, uric acid, and chlorides also. On the succeeding day, however, a corresponding excess of all these excreta is

observed. Sphygmographic tracings, taken before and during the operation of the drug, show that it causes a marked lowering of the systemic blood-pressure, owing to relaxation of the arterioles. It was further noticed by Ringer and Gould, who have published a very careful and precise account of the results produced by the administration of jaborandi to thirty-seven persons, that children were far less susceptible to its action than adults. Even the nausea provoked by the drug failed to excite sweating in some of the younger subjects.

The facts just enumerated suggest the existence of a very curious relation between jaborandi and belladonna, a relation partly of analogy, but mainly of opposition. Jaborandi resembles atropia in quickening the pulse, flushing the face, and in exerting a more decided influence on adults than on children. On the other hand, it is diametrically opposed to atropia in its action on the salivary, sudoral, and mammary secretions, on the pupil, and on the minute arteries. Further, the tendency of belladonna to cause delirium, contrasts with that of jaborandi to cause prostration and sleepiness.

Several of these points have been studied in some detail, and merit further consideration. And first, as regards its sialagogue action: the influence of atropia in checking the flow of saliva from the submaxillary gland has been shown to be independent of the vaso-motor nerves. Heidenhain's experiments, which have since been repeated and extended by others, render it tolerably certain that this phenomenon is due to paralysis of the terminations of the secretory filaments of the chorda tympani. The effect of muscarin (the active principle of the *agaricus muscarius*) has been shown by Schmiedeberg and Koppe to be exactly antagonistic to that of atropia, *i.e.*, to cause profuse salivation by stimulating those nerve-ends which are paralysed by the latter alkaloid. The mode of action of jaborandi seems in this respect to be identical with that of muscarin. It has been proved, both experimentally and clinically, that atropia is able to arrest the flow of saliva caused by jaborandi; and Ringer found that a dose of the latter drug speedily removed the dryness of the mouth in a case of accidental poisoning by atropia. The antagonism between the two is quite as definite in relation to the secretion of sweat as to that of saliva. Sweating after jaborandi may be prevented or checked by the subcutaneous injection of one-hundredth of a grain of atropia. Vulpian has even gone so far as to found a hypothesis concerning the nervous mechanism by which the perspiratory function is regulated, on the analogy of the antagonism in the two cases. He thinks it probable that the activity of the sweat-glands is under the control of nerve-fibres analogous to those supplied to the submaxillary gland by the chorda tympani, and that it is more independent of the vaso-motor system than is commonly supposed.

Next, as regards the eye: belladonna acts, not only on those branches of the third nerve which supply the circular fibres of the iris, but on those which supply the ciliary muscle also. Hence the dilatation of the pupil is accompanied by palsy of accommodation, making near objects seem blurred and indistinct. Tweedy has shown, by experiments on his own eye, that the topical application of an extract of jaborandi causes, not only contraction of the pupil, but temporary myopia, due to spasm of accommodation. There is also some retinal weakness; but the effects are all transient, passing off in a few hours.

The antagonism between belladonna and jaborandi is thus many-sided; its precise limits, however, still remain to be determined. The relation of jaborandi to Calabar bean also requires to be worked out; so far, nothing seems to have been done in this direction. There is still plenty of room for researches like those of which Mr. Langley contributed an instalment in last week's JOURNAL; and such researches are quite certain to bear fruit.

But all this is physiology. We may know that jaborandi has well-marked powers, and yet be ignorant whether those powers admit of being turned to any useful end. To say that a drug is a potent sialagogue and sudorific, is to say very little about its value in the treatment of disease. Mercury is a most active sialagogue; but it is in spite of this property that we continue to give it in secondary syphilis. It may

be that specific virtues of which we know nothing lie wrapped up in the new remedy; but such virtues cannot be discerned *a priori*; they blossom only at rare intervals, and when they are least expected. But short of this highest destiny, the new drug may still have an useful future open to it, not perhaps as a sialagogue—for the practical uses of sialagogues are few—but as a sudorific. At the out-set of acute febrile disorders, such as simple pneumonia, when the skin is dry and pungent; in some forms of chronic Bright's disease, when the arterial tension is high, and the skin can hardly be made to act by hot air baths; in these and similar conditions, jaborandi may be expected to do good service. Its depressant influence on the heart should be remembered; it has been known to do harm in rheumatic fever, complicated by endocarditis. It may, perhaps, find a place in ophthalmic practice, by the side of physostigmin; it may turn out to be a trustworthy antidote in poisoning by belladonna. But these, and all other suggestions must be tested at the bedside; and we may hope that the same competent observers who have furnished us with so much accurate information about the physiological properties of jaborandi, will supply us with evidence of equal scientific value concerning its strictly remedial efficacy. The leaves seem at present to be almost unattainable; but the demand will, doubtless, speedily create an adequate supply.

FALLACIES IN MEDICAL INVESTIGATION.

THE most valuable parts of the able address of Sir William Jenner to the Clinical Society, which we published last week, were, we think, those in which he indicated the true method to be followed in the advancement of medical science, and pointed out some fallacies to be avoided in the investigation of disease.

Of the latter, he mentions the statement of Wunderlich, that "we may exclude typhoid fever when between the fourth and sixth day, in a child or adult under middle age, the temperature never reaches 103.1 deg."—a statement which, Sir W. Jenner says, is evidently based on hospital experience, which, as regards enteric fever, is of little or no value, inasmuch as this fever is rarely sent to hospital earlier than the middle or end of the second week.

Another, and very common, fallacy is what Sir W. Jenner terms incomplete diagnosis. He tells us that the late Sir Benjamin Brodie had great confidence in the bichloride of mercury in the treatment of paraplegia, and that he and others prescribed it indiscriminately in all cases of loss of power in the lower extremities. Sir Benjamin failed to see that the paraplegic cases in which he found the bichloride successful were of syphilitic origin, whilst others who happened to administer the remedy in succession to non-syphilitic cases declared the remedy to be useless. Sir W. Jenner, referring to the want of facts concerning the early symptoms of specific diseases, points out the important service which may be rendered to medical science by the general practitioner; and we hope that Sir W. Jenner's words will not fail to stimulate those in general practice to contribute their quota to the general good.

Speaking of the origin *de novo* of enteric fever, he says:—"I do not say, nor do I think, that the arguments and facts able to be adduced in favour of the origin *de novo* of the contagious diseases are conclusive; but I do say, and I do maintain, that they are strong enough to make us pause before we accept the theory advocated by Dr. William Budd, and to which Professor Tyndall has lent the weight of his great name—a weight which would, however, be greater on the point in question, if he had himself studied the subject on which he has, I am sorry to say, addressed the public in a strain calculated to check unprejudiced individual inquiry." His remarks on the treatment of epidemic diseases ought to be seriously considered by every member of the profession. On this subject, he says:—"When any acute specific disease is epidemic, the educated public call loudly for a cure, and too often, I think, the members of our profession call out as loudly 'Eureka!' Now, to me it seems that there are no grounds for expecting that a cure will ever be found for diseases of this class; that is

to say, for expecting that a drug or medicinal agent will be discovered capable of arresting the progress of the organic changes which, set in motion by a special cause, following each other in definite and ascertained order, constitute what we call an acute specific disease; for, in place of being diseased actions, these several organic changes, the evidence of which we call symptoms, are, so far as our present knowledge extends, processes, the first of which, being called into action by some external cause (for example, the poison of the disease), are essential for the restoration of the intimate organic changes to the order and intensity which constitute health."

BEER AND THE ADULTERATION ACT.

A DEPUTATION of hop-growers and others interested in the purity of beer waited on Mr. Selater-Booth on Tuesday last, to urge upon him the necessity of repressing the adulteration of beer with hop-substitutes.

For a long period, terminating in the year 1862, the adulteration of beer with hop-substitutes was forbidden under penalties; but in 1862, when the duty on hops was repealed, the penal clauses against the use of hop-substitutes lapsed; and since that time the adulteration of beer with bitters of various descriptions has assumed alarming proportions. The extent to which this species of adulteration is now practised may be judged of from the fact (alleged by the deputation) that during last week as much as a hundred and fifty tons of these substitutes were sold.

There is a great deal of mystery attached to these substitutes; but some varieties are believed to consist mainly of quassia. Some of them (we cannot tell with what degree of truth) are said to contain traces of strychnine.

Viewed from the sanitary standpoint, we would remark that, whilst we know that the habitual drinking of hop-beer in moderation is not injurious to the public health, we do not know that strychnine-beer, or even that quassia-beer, would be safe as a general and daily beverage. Hop-beer has been in use for a hundred and fifty years, and has commended itself to the general public; but when hop-beer was first introduced there was much prejudice against it, as there is now against strange bitters, and it would never do to prohibit the making of beer with strange bitters, otherwise we might perchance refuse a bitter better than hop, if such there be in existence.

What the hop-deputation asks is, not that the making of strychnine-beer or quassia-beer may be rendered penal, but that the selling of strychnine-beer or quassia-beer to a customer who wants hop-beer may be prohibited. The hundred and fifty tons of hop-substitute sold last week will by-and-by enter into beer, which will be offered for sale to the public, who will buy it as hop-beer.

Under Section 6 of the new Adulteration Act, it will be possible to prosecute a tradesman who sells quassia-beer under the name of beer (or hop-beer); and if that mischievous word "knowingly", and the perverse clause about "usages of trade" and the warranty-section be removed from the Act, we may hope for convictions.

At a meeting of the members of the Royal Geological Society held on the 11th instant, Sir Robert Kane, M.D., F.R.S., was elected President for the ensuing year.

THE dignity of Knight of the Order of the North Star has been conferred by the King of Sweden and Norway on Dr. Leopold Wittelshofer, editor of the *Wiener Medizinische Wochenschrift*.

THE cross of commander of the Russian order of Stanislaus has been conferred on Professor Zeissl of Vienna, in recognition of his services to science.

It having been determined to close the accounts of the Anstie Memorial Fund this day (Saturday), it is urgently requested that all contributions should be sent immediately to the Honorary Secretaries, Mr. R. Brudenell Carter, 69, Wimpole Street, or to Dr. Wharton Hood, 65, Upper Berkeley Street, London.

PROFESSOR HESCHL of Gratz has been nominated Professor of Pathological Anatomy, and Professor Lieben of Prague Professor of Chemistry, in the University of Vienna.

THE Corporation of Kingston-on-Thames has accepted the offer of the Native Guano Company, to treat the sewage of the town at their own expense and risk, and undertake that no nuisance shall arise from the process.

At a meeting of the Council of the Royal College of Surgeons on Thursday last, the fine portrait of Sir William Fergusson, painted by Rudolf Lehmann, was presented. The engraving from it is nearly completed. The portrait of another President of the College, Mr. Henry Hancoek, painted by Richmond, was publicly presented to that gentlemen at the hospital last week. As a likeness, we cannot speak of it in such high terms as that of Sir William, which is excellent.

THE German Public Health Association will meet in Munich from September 12th to 15th. The meeting of the German Association of Naturalists and Physicians in Gratz will commence on September 18th. Visitors will, therefore, be able to attend both meetings. Several important subjects in sanitary science will be discussed in the Public Health Department of the latter Association.

THE ARTISANS' DWELLINGS BILL.

At a recent meeting of the Marylebone Vestry, the Chairman of the Parliamentary Committee drew attention to the Artisans' Dwellings Bill introduced into Parliament by the Government. A general opinion was expressed that it would have the effect of enormously increasing the rates in most of the large and well-built parishes of the metropolis, as it would hold out a premium to the owners of small and dilapidated property to get rid of it at prices which they could not otherwise obtain in the market; in fact, that it would tax the large suburban and West-end parishes for the reconstruction of the old and tumble down property at the East-end. It was ultimately resolved, to await the action of the other parishes, and co-operate with them in pointing out to the Government the evil effects of the measure as it stands.

EXTRAORDINARY HIGH TEMPERATURE, WITH RECOVERY.

It is ordinarily held in works on temperature, and especially by Wunderlich (*Medical Thermometry*, p. 7), that a temperature of 107.5 degs. is incompatible with recovery; that the temperature may rise, but the rising temperature is destructive to the patient. In an interesting and important paper in the January number of the *American Journal of the Medical Sciences*, on cerebral rheumatism, by Dr. Da Costa of Philadelphia, a case is given of recovery after a temperature of 110 degs. It occurred in an Irish girl with acute rheumatism in the Pennsylvania Hospital. The day after admission, the temperature was 105½ degs.; two days afterwards, the skin was moist, but not excessively damp; the pulse was 120, the respirations 24, the temperature 103.5 degs. In the evening, pulse 104, respirations 24, and temperature 110 degs., two observations confirming this record. This is probably the highest temperature followed by recovery upon record. The practical interest of it is to decrease the hopelessness which attaches itself to temperatures over 107.5 degs.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE following gentlemen have been nominated as the Officers and Council of this Society for the year 1875-76. *President*: *Sir J. Paget, Bart., D.C.L., F.R.S. *Vice-Presidents*: *Edw. Ballard, M.D.; *Sir Wm. Jenner, Bart., M.D., K.C.B., D.C.L., F.R.S.; *Charles Brooke, M.A., F.R.S.; *J. Marshall, F.R.S. *Treasurers*: Wm. Wegg, M.D.; John Birkett. *Secretaries*: *John Harley, M.D., F.L.S.; J. Cooper Forster. *Librarians*: Francis Sibson, M.D., F.R.S.; Timothy Holmes. *Other Members of Council*: *Andrew Clark, M.D.; William H. Dickinson, M.D.; *Wilson Fox, M.D., F.R.S.; William O. Priestley,

M.D.; Hermann Weber, M.D.; George W. Callender, F.R.S.; *George Gaskoin; John Gay; *Thomas Smith; John F. Streatfeild. Those to whose names an asterisk is prefixed have not held the same office during the past year. The annual meeting for the election of officers will take place on Monday next at 8 P.M.

THE PROVIDENT KNOWLEDGE SOCIETY.

WE have received a copy of a tract upon Provident Dispensaries which has recently been published by the Provident Knowledge Society. This Society is under the patronage of Lord Derby, Lord Shaftesbury, and other distinguished men; and Mr. G. C. T. Bartley is the Honorary Secretary. Its object is "to endeavour to make *regular* weekly saving a national habit, and so to increase the facilities for saving that it shall be as easy for a man to put by a small sum as it is now for him to spend that sum in beer or spirits". The Society has published a series of tracts upon *Penny Banks*, *Pensions*, *Insuring One's Life*, and other subjects, which are intended to promote thrift and forethought among the working classes; and of these tracts many thousands have been circulated. The tract before us is the latest of the series, and an excellent pennyworth it is. It deals with the whole question of provident dispensaries, as they can be carried out in villages, in small towns, and in great cities; and a mere glance at the headings of the section is sufficient to show in what a clear, concise, and business-like manner the whole subject has been treated. The aim of the writer evidently is to get rid altogether of gratuitous attendance in sickness, and to bring the provident system within the reach of all. This, we believe, is what the opinion of the medical profession is tending to more and more distinctly; and there can be no doubt that, if it could be carried out, it would be much for the advantage of society at large, as well as an act of justice towards the doctors.

ON SOME EFFECTS PRODUCED BY SEWER-AIR.

AMONGST the subjects which were brought under the notice of the Birmingham Sanitary Conference, in the discussion which followed on the reading of the papers which had been specially prepared, one of the most interesting was the experience which Dr. A. Fergus of Glasgow had acquired after a series of experiments as to the value of water-trapping as a means of preventing sewer-air from entering into dwelling-houses. The principal object Dr. Fergus had in view, was to show that the few inches of water, which are as a rule placed as a barrier between the sewers and the interior of houses, and which are dignified by the name of a syphon-trap, afford in reality no protection against sewer-poisoning. At one time, Dr. Fergus thought it quite possible to keep the results of the decomposition which is constantly going on in sewers out of houses, but he has abandoned this opinion with great reluctance, and he states that he has been led to the views which he now holds, after considerable experiment, observation, and reflection. Dr. Fergus exhibited at the Conference a number of decayed and perforated soil-pipes, the perforations being from within outwards, and being so situated on the upper surface of the pipes, that the destruction of lead could not possibly have been caused by any fluid which had passed through the pipes. The pipe, which was most frequently so affected, was stated to be the cross one, leading from the closet to the main descending soil-pipe; and if there were a bend or arch in the pipe, the upper surface of the bend or arch would become perforated. Now: how does such a destruction of good and well-made soil-pipes take place? Dr. Fergus answers, unhesitatingly, that it is due to the action of sewer-gas; and he supports this view by showing the increased rapidity with which the destructive action takes place, when the soil-pipes are unventilated. Attention, it appears, was first drawn to this condition by the frequency with which complaints were made of offensive odours arising near the water-closets, in houses where cases of enteric fever and diphtheria had occurred; and inquiry as to the general sanitary circumstances of these houses, and as to the history of the patients who were attacked, seemed to leave but little doubt that the offensive and dangerous effluvia emanating from these perforated pipes and the diseases in question, were related to each other as cause and effect.

But what is most striking is the fact that these house soil-pipes were in each case trapped before they entered the drains, and yet the sewer-air was able to get through the trapping and destroy the lead. The question naturally arises, Can this be due to some great tension in the sewer, either from its entering a tidal river or from any other cause, resulting in a temporary failure of the trap? Or, again, Can this state of the soil-pipes be peculiar to Glasgow, and has it been produced by some chemicals getting into the sewers? In answer to these questions, Dr. Fergus, who has dealt fully with this subject, in an address which he delivered before the Sanitary and Social Economy section of the Glasgow Philosophical Society, states that the cause must be one of pretty constant action, sewer-air being absorbed by the water on the sewer side of the trap and discharge on the house side of it, in sufficient quantities to produce the result described; and, with regard to the second question, many inquiries are stated to have been made, and the same thing was found existing in every water-closet town in reference to which Dr. Fergus obtained information. Speaking generally, it appears that where the soil-pipes are closed, or unventilated, this destructive action has been found to take place in about twelve years, the extremes of variation being from a minimum of eight to a maximum of twenty years; whereas when the soil-pipes are ventilated, as by being carried up to the roof of the house where they are left open to the external air, the time required for their perforation may be stated to be nearly double. Applying this experience to water-trapping in general, Dr. Fergus asserts that, however well drains may be trapped, sewer-gas will find its way through them into our houses; and with a view of illustrating this, certain experiments were made, the results of which were brought before the Birmingham Conference. A series of tubes were procured, bent so as to resemble the trap which is ordinarily, though erroneously, called a syphon-trap, and in the lower curve of each of these tubes water was placed to effect the trapping. Various gases were then admitted without pressure into the tubes. The first experiment was carried out with ammonia, and it was found that in fifteen minutes it had passed up the tube through the water, and had discharged the acid with which some litmus paper, suspended over the upper surface of the water, had been reddened. Very similar results were produced with other gases, quite irrespectively of their being lighter or heavier than atmospheric air; thus sulphurous acid passed through the water in an hour, and carbonic acid gas and sulphuretted hydrogen in about three hours. The same experiments were repeated after an open pipe had been inserted into the bend of the tube, so as to resemble the ventilating pipe of an ordinary water-closet soil-pipe, and the same results were obtained, although the reaction was in each case longer in showing itself. The results obtained by Dr. Fergus are extremely interesting, and they point out strongly how misplaced is the confidence which the public have been led to repose in the traps with which every house is provided, and how important it is not only thoroughly to ventilate our house-drains, but to subject our soil-pipes to periodical examination. How far similar results would be produced provided the public sewers were thoroughly ventilated by the admission of an abundance of atmospheric air into them, as well as by the provision of ample means of egress for the foul air, we do not know; but we should hardly be doing justice to Dr. Fergus, unless we stated that he has arrived at the conclusion that excreta should either not be admitted into our sewers at all, or if admitted, they should first be subjected to such chemical action as would render their decomposition impossible.

THE HOSPITAL SATURDAY FUND.

A MEETING of the Council of the Hospital Saturday Fund has been held, to receive the final report of the Audit Committee, to agree to a scheme of distribution, and to make arrangements for this year's collection. The Treasurer's report showed that the total sum raised slightly exceeded £6,300; and, after deducting expenditure, there remained an available balance of £4,900. Out of this balance, the Council proposed that £4,500 should be distributed, while the remainder should be carried forwards towards the expenses of the current

year. It will thus be observed that only a little more than two-thirds of the sum collected has found its way to the institutions which were to be benefited. Further, it was agreed that two-thirds of the amount should be allotted to hospitals, and one-third to dispensaries. This division does not, however, appear to have been strictly maintained, for we notice in the list of dispensaries the names of several special hospitals. The Committee of Distribution presented a report to the meeting, explaining the principles upon which they had made their awards. No grant was allotted to any institution which had not answered the questions sent out by the Council; and these questions, we may mention in passing, were of rather a troublesome and vexatious kind. In each instance, the amount awarded was regulated by marks. The hospitals and dispensaries were drawn up like schoolboys, and examined as to (1) the quantity of work they had done, (2) the economy they had practised, and (3) the efficiency they had shown. To each institution, marks were given under each of these three heads. We have no clue as to the way in which the Committee judged of the efficiency of a hospital, and we imagine that our readers will be considerably astonished at some of the awards which have been made on this score. For example, the Metropolitan Free Hospital stood high on the list, while St. George's and the Middlesex were entirely omitted. We are not surprised that the London Hospital receives the largest award of all; but we are unable to understand why nothing was given to the Charing Cross Hospital, or to the Brompton Hospital for Consumption. Another fact which calls for notice is the large proportion—one-fourth of the whole sum—which was given to special institutions; and among these special institutions are some of most doubtful utility—e.g., the Hospital for Diseases of the Heart, St. Saviour's Hospital, St. Peter's Hospital, the Metropolitan Ear Infirmary, and the Infirmary for Diseases of the Legs. On the whole, neither the collection of the Fund nor its distribution can be deemed satisfactory. If the Committee were tried by their own three tests, how many marks would they receive under each head? The amount of work they have done has certainly not been great; the efficiency of their distribution is most questionable; and what can be said for their economy, since nearly one-third of the money at their disposal has been set aside for expenses?

PURE TOWN WATER.

THE following report is, in many ways, one of very great public interest. It has more than once been shown lately, by the reports of Dr. Carpenter, Dr. Thorne Thorne, and other inspectors of the Local Government Board, that an apparently and usually pure town water-supply is liable to periodic pollution, so long as the supply is on the ordinary intermittent system. This, it will be remembered, afforded a key to the origin of the epidemics at Croydon, Lewes, and Over Darwen. We have, then, in the following report a crucial test of the fact, and a complete evidence of the subtle character of this danger. The instance in point occurred in the house of a well-known analyst, who had been thrown off his guard by the circumstance that the water supplied to his house happened to be tolerably pure at the time he took his first samples.

Report to the Sanitary Committee of the Croydon Local Board of Health.—In compliance with the request of your chairman and of your Medical Officer of Health, I append the more complete details of the pollution of the water-supply at Biggin Hill, together with the effects produced by it upon the health of those affected. On my return to Biggin Cottage after an absence of ten years, I found that my late tenant had left the house in what is termed "habitable repair". The drains gave no annoyance, and the water-pipes only required the attendance of the plumber to secure an ample supply. I was fully aware that the Lambeth Company's water is seldom perfectly wholesome or agreeable, and I was not surprised to find it somewhat turbid and unpleasant to drink. In a short time, however, a continuous disposition to diarrhoea, affecting every one on the premises, led me to take samples of the water to my laboratory for analysis. I found ammonia, free and albuminoid, present to the extent of three parts per million, and a residue of thirty-five grains per gallon, which blackened on ignition. These results, though decidedly objectionable, were scarcely such as to enable me to be sure that the symptoms of illness were due

to the water alone, especially as looseness of bowels is not an uncommon complaint during autumn. I directed my attention to the drains, and saw that they were made good, after which every care was taken to keep them in thorough sanitary condition by means of disinfectants; but still the slight diarrhoea continued, increasing rather than otherwise. Again, I took several samples of the water at different times, and my analyses gave me but the same results. At last, when the late dry autumn was past and heavy rains set in, the continuous intestinal derangement became rapidly worse, and symptoms of low fever appeared. Even the occupants of the stable and kennel were not exempt from the prevalent disorder, and the peculiarity I observed in the fecal discharge was the presence of quantities of columnar cells from the intestines, abortive cytoblasts, and ovoid cells differing in appearance from mucus-corpuses. Large numbers of crystals of ammonio-phosphate of magnesia were usually evident, and cholesterin scales were frequently detected; the more severe symptoms besides purging being cramps, vomiting, and irritation of the liver and kidneys. I was then forced to the conviction that the mischief was in the water, my previous analyses notwithstanding. I ordered samples to be drawn every two hours during the day and night for several days, and this course enabled me to discover that at certain hours of the night the water flowing into my drinking water cistern contained of free and albuminoid ammonia, no less than 4.5 parts per million. The residue, amounting to eighty-five grains per gallon, was composed of nitrates, nitrites, and chlorides, and gave all the other indications of highly dangerous organic contamination. Inquiry soon informed me that much of this poisonous water entered the cistern after the Lambeth Company's water was shut off, and could only have entered the pipes through some defects in them near the top of the hill, the soil through which the pipes pass at that point, as your medical officer's report shows, being saturated with sewage from the adjacent houses and stables. Infiltration from this source undoubtedly does take place, and it only remains to show how it was that such serious contamination could not always be detected by the analysis of samples taken promiscuously. There are two cisterns, one outside the house used only for the garden and for closet purposes; when this is filled, and not before, the water flows from the mains directly into the house-cistern for drinking and culinary use; there is no connection whatever between the two cisterns. Such an arrangement prevents the possibility of any sewer-gases passing into the water and becoming absorbed, a proper and indispensable precaution; but, in this instance, it involved the whole question of the purity of the drinking water in doubt for a serious length of time. When the outer cistern is not full, the contaminated infiltrate flows into it and does not reach the drinking water; but, when there is not sufficient room in this closet-cistern to allow the whole of the infiltrated water to enter there, a greater or lesser quantity of this most dangerous poison must flow into the drinking water. This certainly occurred with frequency enough to occasion long and serious illness in the entire household for some months, but it could not have happened on any of the seven occasions when the earlier samples were taken for analysis. I would impress upon your committee, and the public generally, that all water-pipes are liable to imperfections, and that the ordinary joints of house and stable drains are almost always so far pervious as to cause the surrounding soil to be imbued with sewage. Where, as in this case, water-pipes pass near the drains, and then descend to a lower level to supply cisterns, such an example may not unfrequently be anticipated. There seems to me to be but one absolutely efficient prevention—an invariably constant supply in the Company's mains.—I am your obedient servant, H. C. BARTLETT, Ph.D., F.C.L., Laboratory, 7, South Square, Gray's Inn.

THE OUTBREAK OF ENTERIC FEVER AT LEWES.

THE report presented to the Local Government Board by Dr. Thorne Thorne, on the serious epidemic of enteric fever with which the town of Lewes has been recently visited, has been published. It commences with a general description of the town; it describes the systems of water-supply, sewerage, and excrement disposal obtaining in the place; and the circumstances of the epidemic are then dealt with. In a population of 10,753, as many as 486 cases of enteric fever occurred during the last five months of the past year; and the principal means by which the disease was spread, was, as we have previously pointed out, the passage of the contagium of the fever into water-pipes which passed directly from the mains into water-closet pans. The report contains some additional information which goes to prove that the suction of the contagium into the water-supply was rendered possible by the intermittent character of the water-service; and it shows,

in a conclusive manner, how the provision of a constant water-service led to the arrest of the epidemic. A fortnight before this step was adopted, the fresh cases of fever, which came under observation, numbered 104 in the week; and a fortnight afterwards they had dropped to six only. This constant service, it is believed, will be permanently maintained in the town, and other defects in connection with the water-supply are to be remedied in such a way as to render the recurrence of a similar epidemic impossible.

NEW ADULTERATION BILL.

A PALPABLE and distinctive defect of the amending Bill proposed by Mr. Selater-Booth is that, by introducing the word "knowingly" into the Act, it will throw the onus of proving the amount of knowledge which the offender possesses on the prosecution. A tradesman under the present system becomes amenable to the penalties if he sell any goods which are adulterated; and, as ignorance of the law is held to be no excuse for breaking it, so ignorance of the exact nature of adulterated food is held to be no valid excuse to the vendor. The new Bill, however, entirely sets aside the old legal principle, and gives the very opportunity for which sharp unscrupulous tradesmen have been longing, and of which they will readily avail themselves—viz., the art of cultivating a wilful ignorance in order to evade the penalties of wilful adulteration. Dr. Lyon Playfair truly described this clause as one which invited the passage of the traditional coach and six; and there can be no doubt that the description is thoroughly applicable. The qualifying terms introduced—such as "shall knowingly sell", and "the usages of trade"—are so vague and general, that they can be readily made to cover every known variety of adulterating malpractice. The old plan, which assumed a man to know his own business, and the general constituents of the articles he dealt in, was far preferable; and the sense of the responsibility which it involved tended to make tradesmen careful of the quality of the goods in which they dealt.

RECENT URBAN MORTALITY.

DURING last week, 5,573 births and 4,332 deaths were registered in London and twenty other large towns of the United Kingdom. The mortality was at the rate of 29 deaths annually in every 1,000 persons living. The annual death-rate was 31 per 1,000 in Edinburgh, 34 in Glasgow, and 33 in Dublin. In none of the eighteen large English towns was the rate less than 25 per 1,000. In Bradford, Liverpool, Newcastle-on-Tyne, and Leicester, it was 31; in Birmingham, 32; Norwich, 33; Salford, 33; Wolverhampton, 34; and Manchester, 35. The zymotic rate of mortality was 6.4 in Sunderland, 8.6 in Leicester. Whooping-cough was fatally prevalent in Sunderland, Leicester, and Birmingham; scarlet fever in Hall; and small-pox caused 10 deaths in Birmingham. In London, 2,386 births and 1,801 deaths were registered. The births were 102 below, the deaths 104 above, the average of the week. The annual death-rate was 27, and was highest (28) in the west group of districts. The zymotic deaths were 168, or 82 below the average; 38 were due to scarlet fever, 56 to whooping-cough. The deaths referred to diseases of the respiratory organs were 527, and exceeded the corrected average weekly number by 164. In outer London, the death-rate from all causes and from the seven principal zymotic diseases was 21.4 and 1.6 per 1,000 respectively, against 27.3 and 2.5 in inner London. At Greenwich, the mean reading of the barometer last week was 30.02 inches; the mean temperature of the air was 37.5 deg., or 1.3 deg. below the average. Rain or melted snow was measured to the amount of .25 of an inch.

HOW WE DIE IN LARGE TOWNS.

THE large towns are becoming more and more alive to the importance of the education of the people in sanitary matters; and Birmingham has in several ways set a good example in this respect. Lately, a series of penny lectures on these matters has been given in the Temperance Hall in that town, the subject of the last one being "How we die in large towns", and the lecturer being Dr. Balthazar Foster. The "three great sanitary evils of town-life" were shown by mortality tables to be

—“1. The prevalence of preventable diseases; 2. The excessive mortality among children; 3. The high death-rate from lung diseases among adults.” The first was considered to be due to the density of the population especially; and secondarily to defective water-supply and sewerage; and the compulsory isolation of persons suffering from infectious diseases was advocated. A person who has caught an infectious disease is no longer a harmless citizen, but a very dangerous one, and should be placed in some place where the harm he can do may be as much as possible checked. Such a place is a hospital. The fallacy of the ridiculous argument drawn from the interference with the liberty of the subject was exposed in a few forcible sentences. For children, playgrounds and open-air exercise are wanted, and, *à propos*, we may hope that Mr. Cross's Bill will effect something for us in this direction. The death-rate among adults in towns depends, especially as regards lung-diseases, chiefly upon their occupations, sedentary occupations causing a higher mortality than those in which there is plenty of out-of-door work. The difference between the mortality in towns and in the country among persons over five years of age is not so great as might be expected, but we do not notice that Dr. Foster alluded to the chief cause of this, which is the continual emigration of healthy lives from the country to the town, by which the mortality of the latter is diminished, while that of the country is rendered somewhat higher than it would otherwise be, and so the towns appear to be healthier than they really are. Dr. Foster concluded with some excellent practical remarks about the advantages of pure air, and “plenty of exercise to make us breathe it freely”, recommending the people to take care that the air was continually being changed in the rooms of their houses both by day and night. Lectures of this kind will do much good; for it is chiefly by educating the masses of the people in the laws of health that we must hope to awaken an intelligent interest in the most important matters which concern us all, both as individuals and as members of communities.

ZYMOTIC DISEASES IN LONDON.

ON Saturday last, the Asylum District Small-pox and Fever Hospitals at Homerton and Stockwell contained 203 patients, of whom 97 were suffering from scarlet fever, 68 from fever, and 21 from small-pox. The Small-pox Hospital at Homerton was still empty.

DEATH FROM CHLOROFORM.

WE publish to-day the particulars of another death from chloroform, for which we are indebted to Mr. Arthur Jackson of Sheffield. It is highly important that all such cases should be fully reported, and we have to thank our correspondent for promptly forwarding this notice of his case. The remarkable contribution which we lately published from Dr. Keith of Edinburgh must have done much to satisfy surgeons that ether is not only a much safer anæsthetic than chloroform, but one which answers all the indications of complete surgical anæsthesia. The claims of ether over chloroform are still, we think, not sufficiently recognised in this country.

THE “SPERIMENTALE” PRIZE.

THE prize of five hundred *lire* (£20), awarded annually by the editors of *Lo Sperimentale* to the author of the best original essay published in that journal during the year, has been awarded to Drs. Pietro Albertoni and Felice Lussana, for an elaborate memoir, entitled, “Experimental Researches on Alcohol, on Aldehyde, and on the Vinous Ethers”.

THE TOWN COUNCIL OF WOLVERHAMPTON AND THEIR MEDICAL OFFICER OF HEALTH.

A GENTLE breeze has passed over the Town Council of Wolverhampton, which has ruffled the equanimity of that important body. The time had come round for the re-election of the Medical Officer of Health, who has held the post for three successive years. But it appears that his duties have not been discharged in a way which secured the goodwill and approbation of his professional brethren. Accordingly, the medical staff of the Wolverhampton Hospital held a meeting at mid-

day on Saturday, the 6th instant, and unanimously agreed to write a conjoint letter to the Medical Officer of Health, suggesting his resignation; and, as the re-election was to take place on Monday, the 8th, they asked for an immediate reply—a definite written answer before six o'clock on Saturday evening. It is not surprising that the Medical Officer of Health should have declined to surrender to such a peremptory summons. This was followed up by a memorial, addressed to the Mayor, begging the Council to postpone the election, in order that there might be time to consider the wide-spread feeling of dissatisfaction expressed by the profession as to the manner in which the responsible duties of the appointment had been discharged. This was signed by fourteen practitioners of good standing and high position in the town. On the 8th, the question was considered at the Town Council, the memorial forming the starting point of a very lively discussion. One councillor said, “My opinion about the memorial is that it is the greatest piece of impertinence I ever heard of. The proper mode to deal with it would be to tear it up, and cast it into the waste-paper basket”. Other councillors spoke in high terms of the untiring industry and zeal which the medical officer had displayed in the discharge of his duties, and it was more than hinted that the opposition to his re-appointment arose from prejudice and personal animosity. “Trades unionism among medical men” was the mild term which was applied to the remonstrance of the memorialists. So strong, indeed, was the feeling in favour of the medical officer on the part of some members of the Town Council, that it was proposed to elect him—not for one year—but for three years, or even permanently. But wiser counsels prevailed. Sir John Morris, supported by the ex-mayor, expressed a hope that the appointment would not be made for a longer period than twelve months, because he did not think it safe to assume that a body of gentlemen, like those who had appended their signatures to the memorial, would have done so without having some substantial grounds for taking the course they did”. The amendment proposing a prolongation of the term of office was withdrawn, and the original motion for reappointing the medical officer for one year was carried unanimously. It now remains for the memorialists to make good their case. It is due to themselves, to the medical officer, and to the public of Wolverhampton that the subject should be more fully investigated. They could hardly expect on such short notice, and without entering into any particulars, either that the medical officer would resign, or that the Town Council would postpone his re-election.

LONGEVITY IN GERMANY.

AT the last Prussian census, there were found to be living in Berlin 12,251 persons who were born before the end of the last century. Among them, 3 men and 6 women were 91 years old; 4 men and 9 women, 92 years; 1 man and 5 women, 93 years; 10 persons were 94 years of age; 4 women were 96 years old; 2 men and 2 women, 97; one man, 98; one woman, 99; and another woman, 101. Of the persons between 90 and 100 years of age, 5 were unmarried, 5 married, 57 widowed, and 1 divorced. A widow named Najelsky died on February 10th at Kamionken near Löten, at the age of 103. She is said to have been extraordinarily active even in her hundredth year. A man died a fortnight ago at the age of 105, at Horzitz in Bohemia.

SCOTLAND.

THE COLORADO BEETLE.

AT the last meeting of the Royal Physical Society of Edinburgh, Mr. Gibson exhibited a specimen of the Colorado beetle, and made some remarks as to its *habitat* and history. This creature is believed to be a native of Central America, where it has long been known, and lives upon the leaves and stems of the potato, tomato, and similar plants. About twenty years ago, it began to spread northward and westward, till now it extends from the Pacific to the Atlantic. Its ravages on the potato are quite as severe as those of the fungous disease. The eggs of the

beetle are deposited on the leaves, where they develop into caterpillars, which greedily devour the green parts of the plant, which is thereby killed; the caterpillars then become chrysalides, and so develop into the full-grown beetle; there are several broods in the year. The great fear is that the beetle itself may be introduced into this country in the earth which often surrounds imported potatoes: there is less fear of the larvæ or eggs arriving in a living state. It appears to have great powers of acclimatisation. Two or three years ago, it was unknown in the Eastern States of America and in Canada; now it has a firm hold all over those regions.

DECREASE OF PAUPERISM IN SCOTLAND.

THE report of the Board of Supervision of Scotland, which has just been published, brings out very clearly the interesting fact that, for the last four years, there has been a gradual decrease in the number of persons receiving parochial relief. Last year, the number, both of registered and of casual poor, was less than it has been in any year since the Poor-law Act of 1845, and that in spite of a very considerable increase in the population. In the report, this decrease is attributed to a more careful and stringent consideration of the claims for relief on the part of the parochial boards, and to a more firm and extended use of the poor-house test. The Board has satisfied themselves by personal inquiries that this reduction has been effected without oppression or hardship to any proper object of parochial relief. The pauper lunatics, on the contrary, have steadily increased in number every year for the past ten years, the amount of increase last year being larger than the average rate of increase by nearly 50 per cent.

PROSECUTION UNDER THE MEDICAL ACT.

FROM Airdrie was reported last week the trial of a so-called "medical professor", describing himself as "Professor Chadwick de Banzie, M.D., LL.D.", who was charged with a contravention of the 40th Section of the Medical Act by falsely and wilfully pretending that he was on the *Medical Register*. In answer to the charge, two diplomas, granted to Dr. de Banzie by the University of Philadelphia, were produced as proofs of his graduation. After hearing the Public Prosecutor on the one hand, and the defendant's counsel in reply, the justices found the charge proved, and inflicted the full penalty of £20, or three months' imprisonment. The accused, who had pleaded in defence that he had never pretended to be on the *Register*, gave notice of appeal.

IRELAND.

SMALL-POX has not yet disappeared from Belfast, four deaths having been registered last week as occurring from that disease.

AT a late meeting of the Guardians of the Lismore Union, the salaries of the medical officers of the union were increased each by the sum of £20 *per annum*.

VACCINATION IN BELFAST.

DR. PURDON, factory medical officer at Belfast, has lately published a report on the subject of vaccination in relation to that populous manufacturing town. During the epidemic of 1871, Dr. Baker, one of the inspectors of factories, stated that the directions issued by the Poor-law Board were insufficient to stop the spread of the disease, and, in consequence, was requested by the Secretary of State to draw up a circular for the use of certifying surgeons, suggesting an examination, with the purpose of vaccinating every young person under 16 applying for work; and recommending that employers should make vaccination a condition for employment. The result of these judicious measures has been that, since these directions were issued, 1,000 young persons were vaccinated who had not previously undergone the operation, and at the present time from two to four of those seeking work require to be vaccinated every week. This compulsory vaccination has been of considerable service; for example, in one mill in 1871 there had been 150 cases of small-pox, but in 1874 there were only 10, all being adults.

In 1871, the persons employed in mills, factories, workrooms, etc., numbered 44,318, and of these 837 were attacked by small-pox; but, in 1874, out of 48,650 *employés*, only 176 were affected, 39 of whom were young persons. Stronger evidence than this could hardly be adduced of the benefits of compulsory vaccination.

PORTRUSH WATER-SUPPLY.

A SPECIAL meeting of the Guardians of the Coleraine Union was held on Saturday last, for the purpose of receiving a deputation from the ratepayers of Portrush to take measures for obtaining a supply of pure water for that watering place. A report having been read from a county surveyor, who considered that £3,520 would be required to construct the necessary works, it was determined that the wishes of the deputation should be carried out, and it was resolved that a communication should be sent to the Local Government Board to obtain a loan to execute the works without any delay.

MEDICAL ADVERTISING.

WE incline to think that, since the publication of Mr. James Lane's excellent address at the Harveian Society on this subject, there has been a perceptible tendency to restrict the amount of medical advertising in daily papers. We are, however, by no means disposed to consider that any merely fluctuating change in the character and extent of such advertisements will answer the object in view.

It may be well here to recall the precise words which Mr. Lane used in reference to the practice in which medical publishers have long indulged—and some medical authors exaggerate on their own account—of advertising in the *Times* and other newspapers medical works purporting to be intended only for professional edification. He said:

"I think there can be no doubt that a feeling adverse to the practice in any shape is pretty largely entertained throughout the profession. That being so, the custom seems fairly open to criticism and remark; and it may fairly be questioned whether the practice of advertising medical works on disease of all kinds in the daily journals is conducive to the credit and legitimate advantage of the profession."

"Far be it from me to presume to hint the smallest blame on those who have availed themselves of a custom which has undoubtedly become one of the established usages of the profession. Amongst them may be found many who are entitled to all honour and respect; it is against the custom only that I venture with all deference to enter an humble protest."

"Those who write *for* practice and those who write *from* it—those who only want to say *something*, and those who have something within them which they want to say, both have their representatives in the advertising columns of the daily papers. Will it be thought too presumptuous to suggest to the latter, whose works are really written for the profession and not for the general public, and many of which are an honour alike to their authors and to science, that they might fairly content themselves with the publicity afforded through the medium of the medical press? It cannot be contended that there is any demand for works of this class amongst non-medical readers: the only real effect, then, of such advertisements is to bring the names of their authors prominently before ordinary newspaper readers, an aim hardly worthy of those whose acquirements fit them to be our leaders and our teachers, of whose reputation and fair fame we are jealous, and whose character and motives we wish to see not only without reproach, but above suspicion."

"Now, it is a great encouragement to those who write books for practice, that they have the opportunity of introducing them to general notice in such respectable society, where they can at once flaunt it with some of the best amongst us: but if their betters could be induced to withdraw from the association, if it came to be understood that, to use a prevailing vulgarism, it was 'bad form' to resort to such modes of publicity. Perhaps in time even these notifications would cease to greet the public eye, and aspirants for practice might be led to turn their energies in more legitimate directions, and at all events to make themselves masters of a subject first, and write a book about it afterwards."

We had occasion to point out, in commenting favourably upon these views, that, as one result of the license now accorded to medical publishers, and taken by the publisher of a well-known medical paper, the names of the most eminent medical men—men who are models of professional delicacy, and whose professional career was typical of honour and dignity—were, entirely without their knowledge, paraded with extraordinary prominence across an evening paper, in connection with

purely professional subjects, to promote the sale of the medical paper, or to bring it under public notice. It is quite clear, therefore, that Mr. James Lane was justified in saying that, under the present system, the most eminent men are liable to be dragged into the sort of puffing prominence which they would of their own will carefully eschew; and that they are thus forced into positions which less scrupulous persons thus seek as matters of profitable notoriety.

We have never heard any argument in favour of advertising technical medical books in the newspapers which seemed to have any weight. It has been suggested that not all medical men see medical papers, and an advertisement, say in the *Times*, may be necessary, therefore, to bring a new work under notice. It is, however—looking to the known facts as to the numbers circulated of the leading medical journals—clear that, although no one medical journal is read by the whole profession, yet the total circulation of the principal medical journals is very considerably in excess of the whole number of members of the profession; and, although there may be here and there an eccentric individual, it is difficult to imagine that there is any class of medical readers of books who do not see any medical journal. It would be difficult to find any number of medical men who do not see a medical journal; still more so to conceive that they should be buyers of medical books, and that it should be worth while to carry on a costly system of medical advertising to reach them. It will, indeed, we believe, be generally admitted that the object of advertising medical works in daily papers is to address the lay public, and not the medical public. That is a practice which is surely more honoured in the breach than the observance. A few striking examples will soon suffice to break it down, if we are right in supposing, with Mr. Lane, that it is not accordant with the general feeling of the profession, or conducive to its highest interests. If it be once known that some of the leading members of the profession have directed their publishers to withdraw all advertisements of their books from the daily papers, it will soon be held in this country as “bad style” to allow such advertisements to appear, as it already is in France and elsewhere abroad. We shall be glad when the day comes that we are authorised to make such an announcement, and shall be happy to have contributed to that end.

PROFESSIONAL REMUNERATION.

AN occasional correspondent in Lincoln writes:—“At a meeting of the Lincoln Medical Society held some time since, a Committee was formed for the purpose of discussing the question of professional remuneration, and reporting thereon to a meeting of medical men of the neighbourhood. The Committee, after considerable trouble in obtaining the opinions of the principal members of the profession in the county, have presented their report, which was read at the last meeting of the Society. The report states that while, in consequence of the many different kinds and modes of practice, the various old-fashioned customs, and the hesitation of the profession to lose its title to remuneration on the abstract value of its services, it is impossible to advise a hard and fast line in the matter of professional charges, they are of opinion that some definite system of increased remuneration is very desirable; but unless the leading practitioners are united in carrying it out, it will be useless trying to obtain a proper recognition of their services. If we take into consideration the fact that in most places the amount of remuneration remains the same as for the last twenty years, the increased expense of education for the profession, the enormous increase in the cost of living, the decreased value of money, the greater expenditure by all classes, and the consequently greater difficulty of members of the profession holding their ground, it becomes a matter of the greatest importance that a scale of fees should be drawn up and adopted, calculated to mitigate the evils that arise from the causes indicated. Medical charges must of necessity vary in accordance with the pecuniary resources of the population amongst which the practitioner resides; it is hence impossible to draw up a scale of fees applicable under all circumstances, for clearly it would be useless and injudicious to charge that which patients were unable to pay; still the Committee feel convinced that much may be done towards improving the position of the profession in this respect, if its members will but agree among themselves.

“With regard to what is called ‘Club Practice,’ the Committee are of opinion that there should be restrictions as to the persons eligible to receive medical attendance. These medical clubs were originally instituted to provide pecuniary and medical relief for the labouring classes, and thus prevent them from becoming chargeable on the rates and being pauperised; but of late years, and notably in the city of Lincoln, people of a different class altogether are admitted into clubs. Clubs have, of course, a perfect right to admit whatever class of men they choose; but when tailors, drapers, butchers, publicans, doing good businesses, and retired well-to-do tradesmen, become members, and expect to re-

ceive medical attendance at a charge of about three shillings and six pence a year, the Committee think that the various complaints about this kind of practice have foundation, and that such practice ‘is objectionable in every way, and a great imposition on medical men’.

“At the present time in Lincoln, the majority of the friendly societies have joined themselves into two different dispensaries, each employing its own medical attendant, so that the complaint as regards the previous unsatisfactory state of club-practice is removed, and requires no further comment. The Committee understand that the societies and their late medical attendants are satisfied with the change. In country districts, club-practice will still have to be concurred in; but the Committee think that the payment of each member should not be less than four shillings and fourpence *per annum*; and that persons whose wages, salary, or income, exceeds thirty shillings per week, should not be entitled to medical attendance; and that a fee (not exceeding half a crown) should be charged for examining every new member of a club. The Report concludes by recommending the adoption of the tariff issued by the Shropshire Branch.”

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Copper in the Human Organism.—Causes of Infant Mortality.

IN France, in cases of criminal poisoning, the medical expert is, as a rule, accompanied by a chemist to assist him; and, in giving evidence before a court of justice, each is required to give an account of his work in his own special department. Thus, while it is the duty of the chemist to search for the poison, the medical man looks for lesions in the body of the victim; notes are then compared, and, if they do not tally with the results of works on the subject, the criminal is generally let off, not with the charge of manslaughter, but with “extenuating circumstances”. It is in this way that MM. Bergeron and L'Hôte, the former a medical expert and the latter a chemist, were engaged in the affair of Moreau, who was lately executed for having poisoned his two wives at St. Denis. It will be remembered that, on that occasion, it was discovered that copper was the substance employed, though, during the lifetime of the victims, poisoning by corrosive sublimate was diagnosed, as the symptoms bore more of the character of the latter than of poisoning by copper. The two experts, having recalled to mind the teachings of the celebrated Orfila, that mineral substances are generally found in the great organs of secretion, such as the liver and kidneys, at once examined these organs, and there detected copper; they, however, wished to ascertain whether the liver and kidneys, in their normal condition, contained this metal. In concert together, they then directed their investigations with the view of solving this question, and had an opportunity of carrying them out on fourteen corpses, which they were certain had no copper administered to them during the latter part of their lives. The result of their inquiry was lately submitted to the Academy of Sciences, which may be summed up as follows. In two of the bodies, aged respectively 17, copper was found, but the exact quantity could not be ascertained; in eleven bodies, whose ages ranged from 26 to 58, the maximum quantity found was one *milligramme*; in one individual, aged 78, the quantity was a little over one *milligramme*. MM. Bergeron and L'Hôte explain the presence of copper in the liver and kidneys, by absorption from constant contact with this metal in various ways, such as the use of copper utensils in cooking and other purposes, the handling of copper coin, etc. From these results, the above named gentlemen have come to the following conclusions, which are most important in a medico-legal point of view:—1. Copper is constantly present in the organism, but can be detected in appreciable quantity only in the liver and kidneys; 2. The quantity detected in the greatest number of cases does not amount to two *milligrammes* = $\frac{1}{500}$ ths of a grain.

In referring to the population statistics of France in my last letter, I mentioned, as one of the causes of the depopulation of this country, the limited number of births in proportion to deaths. I cannot here enter into an explanation as to the cause or causes of this limitation in the number of births among the French; I may, however, observe that they are not to be sought in conditions beyond human control. I have heard many a Frenchman repudiate the idea of sterility in his countrywomen, but avow that he was compelled by circumstances to act up to the principles laid down by Malthus. This is certainly part of an explanation, and may be open to question; but there is another potent cause in operation, which cannot be denied, and which is now admitted

by all who take any interest in the matter. I allude to the frightful mortality among the children in France, which, under certain social conditions, amounts to about 50 per cent. in the first year of their existence. M. Bouchut, a well known authority on children, has shown that the mortality among foundlings, now designated "enfants assistés", is nearly double that of the average of infants sent out to nurse, and treble that among infants in general throughout France. The causes of this great mortality are, according to M. Bouchut, to be found in the improper care of infants immediately after their birth, in the influence of the surrounding temperature, in insufficient lactation, which necessitate the having recourse to the "biberon" or feeding bottle; finally, in hereditary syphilis, which is more common among foundlings than among legitimate children. M. Bertillon, a celebrated statistician, has shown, in another report, that the mortality among infants is greater in the thirteen departments surrounding Paris, or rather, the Department of the Seine, than in the rest of France; he estimates it at one-fifth in these departments, whereas it is only a seventh in the rest of France. This difference is explained:—1. By the greater number of infants, legitimate as well as illegitimate, that are abandoned by their parents; 2. By the infants being sent out to nurse, away from the sight of their parents, where they are so ill-cared for; 3. By the great number of endemic or epidemic affections which radiate from Paris to the neighbouring departments. The mode of lactation or feeding has also a great influence on the rate of mortality among infants. According to M. Bouchut, the mortality in Paris is five times greater among infants fed with the bottle than those suckled by a wet-nurse; infants suckled by their mother yield half the number of deaths less than those furnished by infants brought up by wet-nurses: infants brought up by the breast by their mothers in Paris yield a smaller mortality than those brought up by wet-nurses in the country; the cause of the difference is obvious: in the one case, the infants are nursed by their own mother, whereas, in the other, the nurses are strangers to the child; but it is remarkable that, while infants in Paris who are brought up by the hand yield a mortality of 66 per cent., those in the provinces furnish only 44 per cent. This startling difference is ascribed to the better quality of the milk and the greater purity of the air. The conclusion to be drawn from this is, that maternal lactation preserves the lives of more children than mercenary lactation or artificial food, and the strictest attention to this fact would point to one of the most potent remedies against depopulation, and perhaps degradation, about which so much has been said and written within the last few years.

M. Gustave Lagneau, a candidate for the membership of the Academy of Medicine, presented a paper on a subject closely allied to the above; and, according to this learned gentleman, the mortality in the first year of infancy is nearly double in illegitimate children than in those who are legitimate. He ascribes this difference to much the same causes as those mentioned above, and recommends as a remedy the opening of working maternities (*maternités ouvrières*, a sort of work-house) to necessitous women in the family way, whether married or unmarried, where they should be admitted and cared for, not only until their confinement, but even after; where they shall be employed according to their individual capacity, physical as well as intellectual, and be remunerated according to their work. By this means, the women will be enabled to suckle their own children, and, when they leave, M. Lagneau recommends that work should be found them, or that they should have such assistance as would induce them to keep their children, instead of handing them over to strangers. The idea is, to say the least, very philanthropic and plausible in theory; but the question is whether it can be put into practice. M. Lagneau's paper is not confined to infant mortality alone, but it treats of the influence of illegitimacy on mortality at a far greater advanced age. Thus he shows that, out of 1000 registered births, 640 legitimate children reach the age of 20 years; whereas, among the illegitimate, there are only 238. In other words, more than three-fourths of the illegitimate are carried off before they reach the age of 21 years.

ASSOCIATION INTELLIGENCE.

YORKSHIRE BRANCH.

The spring meeting of this Branch will be held at the Infirmary, Huddersfield, on Wednesday, March 10th, at 2.30 P.M.

The members will dine together at the George Hotel at 5 P.M. Tickets, 6s. 6d. each.

Members intending to bring forward any communication, or to join the dinner, are requested to communicate with the Secretary.

W. PROCTER, M.D., *Local Secretary*.

24, Petergate, York, February 19th, 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

The next meeting will be held at the Crystal Palace Hotel, Upper Norwood, on Thursday, March 11th, at 4 P.M.; E. R. Ray, Esq., of Dulwich, in the Chair.

The following communications have been promised.

1. Dr. Galabin: On the Causation of Puerperal Convulsions.

2. Dr. Dalton: On a Case of Recovery from Tubercular Peritonitis, with Cerebral Symptoms.

3. Dr. Miller: On a Case of Cardiac Rheumatism.

Dinner will be served at 6 P.M.; charge, 6s., exclusive of wine.

JOHN H. GALTON, M.D., *Hon. Secretary*.

Woodside, Anerley Road, Upper Norwood, S.E., Feb. 23, 1875.

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

The fourth ordinary meeting of the session was held at the York House, Bath, on Thursday, February 18th; F. MASON, Esq., President, in the Chair. There were also present forty members.

New Members.—The following were elected members of the Association and of the Branch: E. T. Hale, Esq., Bristol, and Percy O. Jones, Esq., Bristol.

Papers, etc.—1. Mr. TIBBITS gave a *résumé* of his paper on Blood-Poisoning.

2. Mr. WAUGH read a paper on a case of Septicæmia. An animated discussion on the two papers followed, in which Drs. Brabazon, Swayne, Shingleton Smith, E. L. Fox, and Messrs. Dowson, Michell Clarke, Steele, and others, took part.

3. Mr. STEELE read an account of a Successful Case of Ovariectomy; and Messrs. Swayne, Clarke, and F. Parsons gave their experiences of the operation.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: ORDINARY MEETING.

The fourth ordinary meeting of the session was held at the Midland Institute on January 21st, 1875. Present—W. C. GARMAN, Esq., President, in the Chair, and thirty-five members and visitors.

New Members.—The following members of the Association were elected members of the Branch: Dr. Wyndham Crowe, Leamington; Dr. J. Johnston, West Bromwich Hospital; Mr. F. Ruffe, Tamworth; Mr. R. W. Edginton, and Mr. W. W. Wilson, Birmingham.

Report on Medical Education.—The amended report of the Committee on Medical Education having been referred to the Branch from a special meeting held on December 17th, the last two clauses of the report were adopted, on the motion of Dr. James Thompson, seconded by Dr. Fowler Bodington. The scheme of medical education appended to the Committee's report coming next under discussion, the Branch resolved to proceed to the next business.

Communications.—1. Mr. LAWSON TAIT showed a preparation of a sessile Ovarian Tumour, round the base of which coursed two ureters, a complication which would have been almost unrecognisable if ovariectomy had been performed during life.

2. Dr. PHILIP BINDLEY showed for Dr. B. FOSTER a specimen of Diseased Lung removed from a patient in the General Hospital, who had suffered from chronic interstitial pneumonia and bronchiectasis. There were very firm pleural adhesions on both sides, but especially at the upper lobes, which rendered the removal of the lung impossible without stripping off the parietal pleura. Except at the extreme bases, where the lung was collapsed and congested, the pleura was converted into a dense mass of fibrous structure, measuring on section at the thickest places, from a quarter to half an inch, and strong bands of fibrous tissue, of an iron-grey tint, and with a consistence almost cartilaginous, passed inwards from the pleura through the substance of the lung. The apex of the lung was broken down into ulcerated cavities of irregular shape, traversed by rugged fibrous bands. Below this, bronchiectasis was most marked. From the root of the lung to the periphery, irregular bronchial dilatations and pouches of various sizes were very numerous, and had so pervaded and encroached upon the true pulmonary tissue, that little of it remained. The bronchi could be easily followed up and slit with the scissors as far as the pleura, where many, even in this neighbourhood, were dilated to the size of a crow-quill. What did remain of the lung-tissue, between the fibrous bands and the dilated bronchial tubes, had entirely lost its spongy character, and was deeply pigmented. These changes had taken place to about an equal extent in each lung. An interesting point in the case was the fact that fibroid changes had not taken place in any of the other organs. Both the liver and kidneys were fatty.

3. Mr. G. H. EVANS read a paper on a case of Perinephric Abscess, with remarks on the diagnosis of such abscesses from those arising from spinal caries. An interesting discussion followed.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 23RD, 1875.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

CONTRIBUTIONS TO THE HISTORY OF LARYNGEAL PHTHISIS.

BY WILLIAM MARCET, M.D., F.R.S.

DR. MARCET divided his paper into two parts; the first being a short account of the history of laryngeal phthisis, and the second a record of his own observations on the subject. The second part began with a remark that laryngeal phthisis is both a symptom and an extension of a pre-existing disease. It is a symptom, because, when its existence is clearly established by laryngoscopic examination, there is no doubt that the lungs either are or will shortly become tubercular, if not obviously so at the time; it is an extension of a disease, because, as a rule (he did not say invariably, although it may be so), the pulmonary tissue first becomes the seat of tubercular growth, mischief appearing subsequently in the larynx. The author's former connection with the Hospital for Consumption and Diseases of the Chest at Brompton had given him a wide field for the investigation of laryngeal phthisis, of which he had availed himself; and he reported in a tabular form 70 cases of disease of the larynx in phthisis, in which both the physical signs of the chest and laryngoscopic appearances were faithfully recorded. This formed the groundwork of his communication. The author inquired into the main predisposing cause of laryngeal phthisis; and, after examining the various trades and employments recorded in 57 cases, came to the conclusion that excessive use of the vocal organ is hardly, if at all, a predisposing cause of that affection. Out of the 57 cases, 30, or a proportion of about 53 per cent., were employed on indoors or sedentary and home work; while, of 399 cases of phthisis attended by the author at the hospital in 1869, all of which were free from laryngeal disease, about 80 were employed on indoor and sedentary work, giving a proportion of 26 per cent. It would, therefore, appear that sedentary and indoor work has a marked influence as a predisposing cause of laryngeal phthisis. A case was recorded, however, where the disease broke out in a butcher's assistant, whose business it was to call out the weights of the meat on the scale; this appears to be a very laborious work for the vocal organ. It was remarkable that there was not a single hawker on the list of cases of laryngeal phthisis. Deficient out-of-door exercise and want of pure air together, it might safely be added, with neglect of the rules of hygiene and mental anxiety, are the main predisposing causes of laryngeal phthisis. The disease, therefore, appeared to be a low form of consumption, and requires as much attention to be paid to the general state of health as to the local mischief, if not more. The author next alluded to a state of weakness of the muscles of the vocal cords occasionally met with in consumption, without there being any organic change in the larynx; and observed that in these cases the tensor muscles of the cords appear more often affected than the adductors, while in hysteria the latter set of muscles are more commonly at fault. Cases were given illustrating both kinds of affections. He afterwards described the appearance of the larynx in laryngeal phthisis, and insisted on the presence of a whitey milky, probably purulent, mucous fluid, in the laryngeal cavity as a means of diagnosis of phthisis. The prognosis, where organic disease is detected in the larynx, in cases of consumption, is not favourable; still, much can be done towards relieving the pain and distress in the throat. The author then stated that there is nothing contagious in laryngeal phthisis, although the expired air from the chest of a person suffering from the disease may be peculiarly irritating to the throat of another in good health. He thought that this irritating property of inspired air equally applies to phthisis, without any affection of the larynx; indeed, he found the air expired by a healthy individual often irritating to the larynx of another person. He cited his own experience on the subject, and remarked that his throat frequently suffered from irritation in consequence of his being called upon to breathe near the mouths of his patients while using the laryngoscope in a succession of cases. Some remarks followed as to the unhealthy character of expired air in other respects; and the author then described the treatment. The application to the larynx of a solution of iodine in olive-oil, or of bromide of potassium in glycerine and gum-water, relieved the pain; and scarification, when the larynx was much swollen, proved beneficial. Inhalations of iodine were also sometimes used with advantage. When the laryngeal mucous membrane was neither ulcerated nor much swollen, faradisation of the muscles of the larynx often succeeded in improving the voice. A few remarks were here introduced on climate. The author believed that, wherever those who suffer from consumption in an

acute form may be living, except, perhaps, if residing high up in the mountains, they will, as a rule, derive benefit from removing to a place higher up, although, perhaps, not distant from their residence, and possibly not more than from one hundred to three hundred feet above it. The *post mortem* changes in the larynx were shortly noticed, and then the author considered the cases he had brought forward. He related the history of two patients, with laryngeal affections, who both recovered; one of them exhibited rather suspicious symptoms of phthisis, while the other case was one of acute laryngitis, with aphonia accompanying pulmonary congestion. The conclusions derived from the consideration of the table of 70 cases of diseased larynx in phthisis, in all of which the physical signs of the chest were reported, were as follows. 1. More men than women were affected, in the proportion of about two of the former to one of the latter. 2. The ages recorded in 55 instances appeared to show that most cases of laryngeal phthisis are met with between the ages of twenty and thirty years, or at that of thirty and above twenty. Dr. J. E. Pollock states (*Elements of Prognosis in Consumption*) that there is a large preponderance of cases of phthisis between those ages; and, therefore, as far as age is concerned, the predisposition appears to apply equally to consumption, whether the throat be affected or not. 3. Out of 70 cases of phthisis, in which the larynx was affected, eight of them exhibited no visible organic change, with the exception of slight redness with congestion in two of the eight cases; tension of the vocal cords was deficient in five; in the three other cases, adduction of the cords was deficient in two, and abnormal in one. 4. In 31 cases out of the 70, the epiglottis was affected (a statement of the nature of the change in every case was given). 5. Only 13 cases were recorded of positive ulceration of the larynx out of the 70—this proportion appearing rather smaller than might have been anticipated. Patients with laryngeal ulcerations are, as a rule, older than those whose larynx, although affected, is not ulcerated. The mean age of the patients suffering from ulcerations in the larynx was 38 years, while the mean age of those whose larynx was free from ulceration was 29.7 years; the author concluding that want of nutrition due to age appears to act as a predisposing cause of laryngeal ulceration. 6. Dysphagia, or difficulty in swallowing, was noted in 14 cases; but this symptom may, perhaps, have existed in others, although not recorded. As a rule, there is pain and dysphagia whenever the epiglottis is affected; although, where that organ is merely congested and streaked (without being indurated) by the presence of enlarged vessels, the discomfort may be very slight indeed, and hardly noticed by the patient. 7. Aphonia, or some alteration of the voice, was reported in 59 out of the 70 cases. Of the other 11, it was concluded from the state of the larynx that the voice was probably weak or otherwise affected in 9.

The PRESIDENT said that many cases of laryngeal phthisis had fallen under his notice. He agreed very much with Dr. Marcet, that it was rather a modification of ordinary phthisis than a disease in itself. The laryngeal complication was usually a serious aggravation of phthisis, and hastened the fatal termination by adding distressing symptoms and interfering with the treatment. The cough was very harassing; it might be called a fruitless cough, inasmuch as it was attended with but little expectoration. The loss of voice was also very distressing, and had a depressing effect on the patient. There was also, perhaps more frequently than Dr. Marcet seemed to think, difficult or rather painful deglutition, often from ulceration of the larynx rather than of the epiglottis. When the epiglottis was diseased, the passage of food over the glottis produced grievous irritation; and hence it was necessary in such cases to give food in as bland a form as possible, so that a sufficient quantity might be taken; for the fatal course of the disease was much accelerated by any interference with nutrition. The general tendency of laryngeal phthisis was to hasten death; but Dr. Williams had known some exceptions in which, after indications of pulmonary disease were present, the larynx was attacked, and became apparently the chief seat of disease. He referred especially to one case of the kind where, although there were at first distinct symptoms of pulmonary disease, nothing was found in the lungs after death but a few patches of withered tubercle, while the larynx not only presented extensive tubercular disease, but there was necrosis of the cartilages. Such cases, however, were exceptional. In the treatment, constitutional remedies were very important; cod-liver oil, etc., must be given. He had been much disappointed in treating laryngeal phthisis, and, indeed, chronic laryngitis, by local remedies. He agreed with Dr. Marcet that in most cases nitrate of silver and similar articles did more harm than good. In a few cases, the application of nitrate of silver by Dr. Horace Green's method had been useful; but he had met with so many failures from this treatment, that he had laid it aside. The use of spray was more applicable, and sometimes more successful; but even with this the results had fallen short of his expectations. He concluded that it was only in a limited number of cases that these remedies were useful. Spray should

be used in summer and hot inhalations in winter; he had found the use of spray in cold weather injurious. It was useful to employ a weak solution of carbolic acid in the form of spray; it acted as a soothing agent, and as an alternative of the secretion. He agreed with Dr. Marcet as to the offensive and acrid nature of the exhalation from the larynx in the disease; and for the correction of this, creasote, carbolic acid, and the oil of the *Pinus sylvestris*, were useful. Sometimes a very weak solution of nitrate of silver, of sulphate of copper, or of acetate of lead, allayed the irritation for a time. Inhalation was useful in cold weather; but it must be remembered that it was liable to produce perspiration, and hence the patient should be cautioned not to use it except at bed-time and when he was not exposed to cold. The various forms of inhaling apparatus showed much ingenuity, but the tubes were generally too small; they ought to be twice or three times as large. A simple and useful form which he employed was a jug of hot water containing the medicinal substance to be inhaled, the patient inhaling under a napkin lying over his face and covering the jug. The medicinal substance to be inhaled must be volatile; it was sometimes recommended to add non-volatile metallic salts to the water; and even iodine was volatilised with some difficulty. In general, creasote or carbolic acid, with hemlock, or in some cases chloroform, were most useful. The recommendation to use iodine both internally and externally deserved consideration. Many remedies might be given in oil or glycerine which were too irritating to be administered in other ways. Even water-vapour itself, in the form of spray, was irritating to the larynx, and of course more so when containing other substances; hence the addition of oil and glycerine was worthy of consideration.—Dr. DRYSDALE said that it seemed to him, from observation of many cases, that the prognosis in laryngeal phthisis was fatal, except where the patient could go to a warmer climate; and, under these circumstances, he had known a few cases where life had been prolonged for years, just as in other cases of phthisis. As a general rule, he thought that the course of laryngeal phthisis towards death was very rapid. He had seen relief produced by the inhalation of iodine vapour. As to the diagnosis, there was a difficulty, as had been well pointed out by Dr. Marcet, in distinguishing between laryngeal phthisis and syphilitic disease of the larynx; especially in such cases as one to which he referred, in which laryngeal phthisis occurred in a patient who presented distinct signs of syphilis.—Dr. THIN said that, in travelling in America, he had visited Salt Lake City, and had obtained some interesting information from a medical man there. The plateau on which the city stood was about four thousand feet above the level of the sea. Among the native white population, he was informed, phthisis never occurred. Among the converts to Mormonism who came from the eastern parts of America and from Europe, there were sometimes persons, especially women, who had slight symptoms of phthisis before setting out; during the journey, the disease often became much aggravated; but after their arrival, unless they were in the very last stage of the malady, arrest and cure of the disease almost invariably took place. He believed that this fact was not generally known. He doubted the propriety of making scarifications of the larynx in laryngeal phthisis, as he believed that the resulting effusion might become a source of tuberculous growth.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, FEBRUARY 3RD, 1875.

W. O. PRIESTLEY, M.D., F.R.C.P., President, in the Chair.

Professor Gustav Simon, M.D. (Heidelberg), and Professor Courty, M.D. (Montpellier), were elected honorary fellows of the Society.

President's Address.—The PRESIDENT delivered his inaugural address.

Professor CASELLAN of Milan presented his transfusion-apparatus.

Adhesion of Uterus to Intestines.—Dr. T. C. HAYES exhibited an uterus and appendages which were connected by adhesions in several places to the large intestines. The patient, aged 42, had had two children and four miscarriages; had been subject to frequent and copious menorrhagia, and latterly had three or four attacks of hæmatemesis. She lived in India several years, where she had ague and rheumatic fever. She was admitted into King's College Hospital, suffering from cardiac disease, contraction of the liver, and enlargement of spleen, associated with ascites and oedema of the legs. Death resulted after an attack of hæmatemesis. There was no reason to suppose that she had been intemperate, nor was there any clear evidence of her having had syphilis. In spite of the adhesions, the uterus was remarkably movable. The menorrhagia was doubtless passive, and was probably intensified by the serious obstruction to the return of blood from the uterus, caused by the adhesions.—The PRESIDENT inquired whether there was any history of previous pelvic peritonitis; to which Dr. Hayes

replied in the negative. The President remarked that the amount of pelvic adhesions, and the absence of any history to explain them, was a point of interest.—Dr. EDIS alluded to a case of his, recently published, where Bright's disease was the exciting cause of profuse menorrhagia, this latter being often dependent upon the most varied conditions, both general and local.

The Couch-aid.—Dr. EDIS exhibited for Dr. E. Diver an apparatus designed to assist labour and economise force during parturition, enabling the patient, by pulling during her pains, to give comfortable pressure to the back, and support to the uterus at the same time. It consisted of a cushioned back pad, and another for the front, with two stirrups for the feet, and a series of connecting straps and cords.—Dr. AVELING thought the ingenious apparatus for accelerating labour, just exhibited, ought to be used with the greatest caution. He feared that, more particularly in the early stages of labour, if not carefully applied, it might have exactly the opposite effect to the one desired; and, as the patient herself had to use it, it was necessary that she should be at the time composed, or, at least, quite mistress of her own actions. A severe pain might either cause her to abandon it altogether, or use it too violently. He thought pressure by the hand preferable.—Dr. MURRAY objected to the apparatus, on the score that it would be advertised as recommended by the Obstetrical Society. He thought we had sufficient to attend to in looking after the mother and child, without complicating matters by applying any such apparatus.

Aborted Ovum.—Dr. EDIS exhibited an ovum expelled about the eighth week, showing the villi of the chorion. The decidua membrane had not been passed.—The PRESIDENT remarked that it was a pity the outer coats had not been obtained, so as to make the specimen complete.

Speculum Trough.—Dr. EDIS showed an India-rubber trough which he had designed to fit over any speculum, so as to prevent wetting the bed in cases where it was necessary to employ the syringe. He had tried it in several cases, and found it answered the purpose well. It was similar to the ordinary ear-trough, except that, being elastic, it could be readily attached to any speculum, and did not interfere with any manipulations that might be necessary.

Report of Three Cases of Cephalotripsy.—Dr. BRAXTON HICKS narrated the history of three cases in which he had resorted successfully to this operation, illustrating his remarks by the casts of two heads taken before the removal of the instrument. He employed it as a tractor as well as a crusher, and felt confident that it would, in the main, supersede the crotchet and craniotomy-forceps in all cases of severity. In the first case, the bony outlet was so small that the hand could not be passed up to the brim; delivery was effected by the cephalotribe, after the crotchet and craniotomy-forceps had failed. In the second case, the breech presented, and the labour was very tedious, the conjugate diameter of the brim being only about two inches. The third case occurred in a primipara, four feet three inches high, small sized in every way and hollow backed. The two latter recovered perfectly in a fortnight; the first case succumbed on the fifth day.—Dr. MURRAY inquired if Dr. Hicks had ever known the instrument to slip. It seemed to him (Dr. Murray) that its principal value was that of a tractor; as to pressure on either side, it was merely a change in the bulk of the head. He had never used the cephalotribe himself, but if the head were not perforated, lessening it one way would only increase it in the other. Without wishing to disparage the instrument, he thought that if we were able to attain sufficient power with the hook and forceps, delivery would be quite as easy as with the cephalotribe, especially as Dr. Hicks said it would supersede the craniotomy-forceps or blunt hook after perforation.—Dr. HICKS stated that he always perforated first. If the head were too high, it was no case for cephalotripsy. It acted as a crusher and tractor; there was no outbulging.—Dr. PLAYFAIR thought Dr. Murray's objection was based on the fact he stated, viz., that he had never used the cephalotribe. Any one who had done so must at once admit its immense superiority; and it was strange that, even after many years of use, teachers recommended the crotchet and craniotomy-forceps for ordinary cases, instead of teaching, as they ought, that the cephalotribe was the proper resource whenever it could be used. No better proof could be given of its value, than the last of Dr. Hicks's cases, in which two experienced operators, medical officers to one of our largest obstetric charities, had failed to deliver with the older instruments, when the cephalotribe had succeeded. Could any evidence of its value be stronger? One particular value of the operation was also well illustrated by the paper, viz., the safety of the maternal soft parts, which were effectually preserved from injury by the spicula of bone, in consequence of their being within the scalp. Hence the dangers arising from picking away the broken bones was entirely avoided.—Dr. HEYWOOD SMITH said that one of the chief advantages of cephalotripsy was the rapidity with which delivery was accomplished; and

this was an element of great importance, for the cases were generally those where labour had been prolonged until the mother's powers were becoming exhausted, and where every minute saved was of the utmost importance. He, unlike Dr. Murray, had never performed craniotomy proper, and, in all the cases where he had been compelled to perform cephalotripsy, the facility of delivery was one of the remarkable features. Perforation, of course, was first employed.—The PRESIDENT had often been struck, in operating, with the uselessness of many instruments. Where the skull was firm, even Sir James Simpson's cranioclast was useless. With the cephalotribe, the bones were broken down more readily, and a firmer hold was obtained than by other means. In some cases, the spinal hook of Dr. Oldham's was most efficient.—Dr. HICKS, in reply, stated that he had found the head expand after removing the instrument, not because of the brain within, because by passing the perforator three or four times through it, its resistance was overcome, but it expanded from its own elasticity tending to recover the globular form; this he had proved by frequent experiment, and, therefore, he had many times in this Society pointed out the advantage of drawing down by the cephalotribe, in opposition to the French recommendation that it should be removed, and the head allowed to be expelled by natural efforts, or drawn down by crotchet. With regard to the remarks which fell from the President, he said that till he had employed the cephalotribe, he was much indebted to the cranioclast of Sir James Simpson. But with regard to the use of Dr. Oldham's vertebral hook and the fixing the crotchet in the foramen magnum, he thought there had been much misapprehension. With regard to the crotchet, it could not pass into the vertebral opening, but if it could catch the sella Turcica, or if Dr. Oldham's hook were passed into the foramen magnum, this did not assist the descent of the head; for, if the cranial base measured three inches, and the brim only two inches, no amount of pulling would conquer the difficulty; all that was required was bringing the head side or face ways. From some unaccountable error, a constant answer from students to the question, how would you draw down the head after perforation, was, "by the vertebral hook!" No other instrument was thought of. The vertebral hook was invented by Dr. Oldham to seize the head which had been torn off the body in breech-presentations, by being passed into the spinal foramen of the remaining vertebrae. With regard to the advantage of the cephalotribe over the crotchet and craniotomy-forceps, it must be remembered that these instruments can only act by virtue of the compression of the mutilated head against the vaginal walls, and, therefore, the pressure was in direct ratio to the traction employed; whereas the cephalotribe, by compressing the head, directly removed all the pressure and friction in a fourth of the time, and even, in some cases, in a tenth, it would take to deliver by the old plan.—Dr. HAYES stated that some French authors advocated clearing out the brain before applying the cephalotribe. Dr. Hicks seemed always to stir the brain up well and so break it up.

Uterus from a Case of nearly Sudden Death.—Dr. HEYWOOD SMITH exhibited the uterus and ovaries of a woman, aged 26, who had died the previous day, within fifteen minutes of hemorrhage into the pelvis. She had been confined sixteen days. On the third day, she had a sharp attack of puerperal septicæmia, from which she, with difficulty, recovered. She had been sitting up for two days, when suddenly, about 12.30 p.m., she became faint, struggled violently, became blind, and died in less than a quarter of an hour, retaining her consciousness until the last. At the *post mortem* examination, the pelvis was found full of blood. The uterus was insufficiently contracted—probably the result of the attack of septicæmia; the left oviduct was adherent to the broad ligament as the result of recent inflammation, and on the left ovary was a small opening. The right ovary was studded with small cysts. In reply to the President, he stated that the source of the hemorrhage had not been discovered. Dr. BLOXAM remarked that, given the conditions stated by Dr. Smith, those who were familiar with the symptoms of pelvic hæmatocele, and with the fearful organic shock attending the outpouring of blood into the peritoneal cavity, would expect such a patient rapidly to succumb.—The PRESIDENT requested Drs. Playfair, Bloxam, and H. Smith, to examine the specimen further, with the view of discovering the source of hemorrhage.

Note on the Treatment of Chlorosis and Anæmia with the Phosphide of Zinc.—Mr. J. ASHURTON THOMPSON communicated a short paper exemplifying the advantage of employing this drug. It succeeded in relieving the symptoms where iron had failed, and that rapidly. Phosphorus was of great value in the treatment of patients recovering from uterine hemorrhage, and in all cases of anæmia; and seemed to exercise a specific influence upon the neuralgia so often met with in these cases, encouraging the general nutrition of the body. Free phosphorus was not the treacherous poison it had hitherto been considered to be. It was a fatal and potent poison, it was true; but its thera-

peutic effects might be obtained with precision and perfect safety. If proper formulæ were employed, no apprehension of unexpected or uncontrollable poisonous effects of a therapeutic dose need hinder its general employment.—Dr. ROUTH said, it might be known to some members of the Society, that he had made several inquiries on the employment of phosphorus. In some cases it produced marvels, especially in cases like those detailed by Mr. Thompson, due to deficiency of phosphorus in the system. But it occasionally acted injuriously; producing headache and giddiness, and, in a few cases (of idiosyncrasy, perhaps,) it acted as a deadly poison even in the first dose, sometimes immediately, producing vomiting and syncope. The safest preparation was the phosphide of zinc, but it was a medicine to be closely watched when given.—Dr. TILT inquired, what preparation of phosphorus Mr. Thompson recommended?—Mr. THOMPSON said, Dr. Routh had revived the old objection; not because it was a poison, but because we cannot calculate the results. These arose from decomposed phosphorus.—Dr. PLAYFAIR inquired, whether the zinc phosphide was not insoluble in pill?—Mr. THOMPSON replied, that some acid tonic given simultaneously would serve to assist the decomposition.

The Treatment of Rigid Perineum, and the Avoidance of its Rupture.—Mr. TRESTRAIL (of Aldershot) read a communication on this subject. In cases where the perineum was long and firm, he materially shortened labour by hitching two or three fingers into the posterior commissure and keeping up extension, thus speedily enlarging the outlet and obviating the necessity for employing the forceps. He cited a case illustrating this method.

Cases of Prolapsus Uteri treated by Dr. Vulliamy's Pessary.—Dr. A. CORDES (of Geneva) communicated the history of two cases treated by this instrument, which consists of a Hodge's pessary bent upon itself.

HARVEIAN SOCIETY OF LONDON.

FEBRUARY 18TH, 1875.

W. H. BROADBENT, M.D., President in the Chair.

Treatment of Primary Diseases of the Heart.—Dr. MILNER FOTHERGILL read a paper upon the treatment of primary diseases of the heart. He said that the successful treatment of diseases of the heart, perhaps more than that of any other class of ailments, rested upon an accurate diagnosis. It was of the utmost importance, then, to decide in each case as to whether the heart symptoms arose from some affection of the heart itself, or they were secondary, and due to some disturbance in the vascular system, standing in a causal relationship to them. The treatment of the first class of heart affections was directed to the condition of the heart itself. In the second division, the true line of practice was to remove the exciting cause, and thus to relieve the heart. The primary affections of the heart were valvular or muscular. When a valve was injured, a compensatory growth of the muscular structure usually followed. If the disease were stenosis, then hypertrophy of the muscular chamber behind the lesion enabled an equal amount of blood to be driven through a narrowed opening in an equal time—and thus perfect compensation was attained, as long as the muscular wall is structurally sound. This was best seen in aortic stenosis. Hypertrophy at other times was developed not to overcome some obstruction in front, but to limit dilatation when the muscular chambers were distended by an incoming current of blood of unwonted force. This was the case in aortic regurgitation very markedly; and was also common in mitral regurgitation when the left ventricle was distended by an inrush of blood from the gorged auricle and pulmonary veins. At other times the disease consisted of muscular debility, without valvular lesion. Cases were given illustrating the complete recovery of the heart from conditions of temporary dilatation. The line of treatment pursued in the cases was rest, at first, and the steady administration of digitalis and iron. The administration of digitalis might be continued for years uninterruptedly, without the production of those toxic symptoms which were supposed by older writers to indicate some cumulative action in this drug. As well as acting directly upon the heart in advanced cases with dropsical effusion, Dr. Fothergill spoke strongly in favour of the use of cathartics, to relieve the venous congestion. He gave a case where two scruples of compound jalap powder were given every alternate morning, till eight doses had been taken, with excellent effects. The depressing effect of free purgation is more than compensated by the relief afforded in these cases. Digitalis and iron were also given, and the catharsis was only supplementary to the direct treatment of the heart itself. To illustrate what might be attained by such direct treatment of the heart, Dr. Fothergill adduced a case of mitral regurgitation in a young man, in whom a murmur could no longer be heard, and the subjective symptoms of disease of the heart had also vanished. Here the vela of the mitral valve were in-

jured, and when the left ventricle was dilated, the injured valves were no longer equal to closing the ostium on the ventricular systole. The reduction of the ventricle to its normal size had resulted in the valves being once more competent; and as long as the ventricle can be maintained in a normal and undilated condition, the equivalent of a cure is attained. In mitral disease the use of digitalis is almost universally admitted, but there is less agreement as to its use in aortic disease. In Dr. Fothergill's opinion, its utility in aortic stenosis was obvious. In aortic regurgitation in the early stages, it was contraindicated, and an agent of precisely opposite qualities—one that would lessen the force of the ventricular contraction, and at the same time increase the number of beats—should be adopted, if we possessed such an agent. In the later stages, however, when the muscular walls were failing, and death threatened from cardiac syncope, then digitalis was useful as a palliative agent. Valvular disease of the right side of the heart, and especially tricuspid disease, was little amenable to treatment, because no muscular hypertrophy could be brought to bear on it. Dr. Fothergill summed up the treatment of primary diseases of the heart as follows: 1. It is of the utmost moment in these cases to reduce the demand upon the heart to a minimum. 2. Much relief may be afforded where dropsy is present, by unloading the congested venous system; and for this end cathartics are very serviceable. 3. The heart must be acted upon directly, by means of agents which increase the vigour of the ventricular contractions, of which digitalis is the chief. 4. To improve the general condition by the use of chalybeates and suitable food is also very desirable. Digitalis and iron may be continued for years, not only without any evil consequences, but with much advantage in many cases. The treatment of secondary affections of the heart would form the subject of another paper.—A discussion followed, in which the President, Dr. Hare, and Messrs. J. W. Langmore, Lawrence, and Sedgwick took part.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

TUESDAY, JANUARY 26TH, 1875.

W. T. GAIRDNER, M.D., President, in the Chair.

Shred of Hydatid (?) or Raisin-Skin (?).—Dr. MACLAREN showed a specimen like a piece of the skin of a raisin, said to have been passed *per urethram* by a man under his care at the hospital, who was supposed to have a hydatid tumour of the liver. This had been tapped twice, and about one hundred ounces of chocolate-and-cream-like fluid removed. No hooklets were found in this fluid. Inflammatory symptoms subsequently occurred; and, three weeks after the second tapping, the patient passed half a chamber-potful of dark fluid, similar to that removed from the tumour; the urethra had become obstructed, it was said, for a time; and, after this was overcome, the patient produced the specimen shown as the cause of the obstruction; since then, the grave symptoms had somewhat improved. Dr. MacLaren did not think the man guilty of imposture; but he had been eating yellow grapes, and possibly this might prove to be the skin of one.—Dr. Joseph Coats and Dr. Thomas Reid were appointed to examine the shred.—[At the next meeting, they reported that the structure was clearly vegetable; the cells were larger than animal cells, and by the iodine reaction starch was plainly made out.]

Recurrent Tumour.—Dr. HECTOR C. CAMERON showed the patient, from whose breast he had removed three tumours, formerly shown to the Society. A fourth had now grown, and it seemed much more adherent to the subjacent tissues than the former ones.

Deficiency of Corpus Callosum in an Idiot.—Dr. ALEXANDER ROBERTSON showed the brain of an idiot, in which the corpus callosum was absent.—A committee was appointed to report on the case to a subsequent meeting (in March.)

Impacted Pessary for Five Years: Vesico-Vaginal Fistula.—Dr. GEORGE BUCHANAN showed a pessary (apparently Zwanke's) crusted over with phosphates, which had remained in the vagina for five years, part of the instrument projecting from the vulva. Urine passed down by the side of the instrument; and, on its being removed, without much trouble, a large vesico-vaginal fistula was found.—Dr. GAIRDNER said he made a *post mortem* examination in 1851, in a case with long standing uterine symptoms, and in which death had resulted from acute pulmonary tuberculosis. In the lower part of the abdomen, there were the appearances of peritonitis, partly perhaps tubercular, with adhesions and matting together of the pelvic organs; and at the fundus uteri something hard was found. A "stem-pessary" was found at the top of the vagina, the stem being imbedded in the wall of the uterus just under the peritoneum. This had evidently given rise to chronic peritonitis, etc., and the pulmonary tuberculosis was no doubt secondary to the

pelvic mischief. The case had been diagnosed during life as one of uterine fibroid, but the verdict after the *post mortem* examination should have been "Died of Pessary".—Dr. GEORGE BUCHANAN thought that in elderly women, without discharges of any kind from the womb, more or less complete occlusion of the vagina by operation was a procedure that should be more often carried out in bad cases of procidentia uteri than it was, as affording a better remedy than the use of pessaries.

Hyperæsthesia of Fingers: Success of Galvanism.—Dr. FINLAYSON presented the boy with hyperæsthesia of the fingers, shown to the Society this time last year (BRITISH MEDICAL JOURNAL, March 28th, 1874). He had since been treated by galvanism, and might now be said to be quite well. The treatment was begun at the end of January, and continued till the middle or end of March. A descending current from seventeen to twenty elements of Weiss's battery was applied two or three times a week at first, and latterly less often. The current was passed steadily from the spine to the hand immersed in salt water, or from the spine to the nerve-trunk, or from the nerve-trunk to the hand, about ten minutes for each segment, the whole proceeding occupying twenty or thirty minutes. After the first two or three applications, in which the current was more acutely felt in the affected fingers than in the others, a very marked improvement was noticed; this special sensitiveness to the current diminished and passed away, and ultimately the degree of hyperæsthesia became so slight that further treatment seemed superfluous. A fortnight ago, the state of the fingers was examined; the affected fingers bore irritation as well as the others; their tactile sensibility, which had been slightly impaired, was now as nearly as possible normal, and there was now no tenderness over the spine or over the nerve. Dr. Finlayson thought that, while part of the recovery might be due to the boy's leaving off his manual work and to the effect of time, the rapid improvement after a month's stationary condition, under rest and belladonna externally (before the electrical treatment began), pointed clearly to the beneficial action of galvanism, as, when shown to the Society last year, the case had a somewhat threatening aspect.—Dr. CAMERON, who had formerly presented the boy to the Society, said the best evidence of the cure was the ability of the boy to use his hands now as well as ever.—Dr. GAIRDNER thought the recovery of the tactile sensibility was the most satisfactory sign of cure; hyperæsthesia was a misnomer, the name should be paræsthesia, for with the painful sensations there was almost invariably a diminution of the tactile sensibility.

Brain of an Aphasic.—Dr. ALEXANDER ROBERTSON showed the brain of a patient long under observation, affected with aphasia.—The case was remitted to a committee for report.

Croupal Membrane.—Dr. ALEXANDER ROBERTSON showed a specimen from an infant, aged nineteen months. The illness seemed to be of five days' duration altogether. When he first saw the child, a few hours before death, the state of the chest and the general exhaustion precluded any prospect of relief by operation. The specimen showed a complete cast of both larynx and trachea. The false membrane did not extend higher than the rima glottidis, but below it was prolonged into both bronchi, although in them it was thinner and less complete. The connection with the mucous membrane was nowhere intimate, and in some parts there was a separation. Above the vocal cords, and on the under surface of the epiglottis, the membrane was thickened, but there was no morbid structure there, and no diphtheritic exudation on the tonsils, pharynx, or parts in the neighbourhood.

Aortic Aneurism protruding into Right Auricle.—The case was published in another connection in the BRITISH MEDICAL JOURNAL, April 18th, 1874, by Dr. ALEXANDER ROBERTSON, who then called attention to epilepsy being preceded by coloured vision in the patient, and followed by partial loss of recognition of the special colour, followed also by temporary aphasia and hemiplegia; no distinct pathological condition, however, was found in any part of the brain. The woman was forty-five years old at death; the cause of death was general dropsy, with effusion into the pleural cavities; there was undue præcordial dulness on percussion, and at the base the two sounds of the heart were merged into a loud murmur. The heart was very much enlarged. Just beyond the aortic valves, there was an aperture in the aorta about three quarters of an inch in diameter, leading into a cavity in the substance of the heart large enough to hold a large plum; its wall projected into the right auricle, and probably encroached on it considerably when distended with blood.

Aneurism of Aorta perforating Right Ventricle.—Dr. JOSEPH COATS showed an aneurism perforating the right ventricle. The aneurism was situated just above the aortic valve, and consisted of a shallow pouch, which projected into the right ventricle just below the pulmonary valve and between two of its semilunar folds. At the most prominent part of this projection, there was a minute perforation. Alongside of this aneurism, there was another shallow pouch which projected externally,

and the aortic arch, as a whole, was very atheromatous.—Dr. PERRY described the symptoms observed during life in this case, but they had no special reference to the peculiar lesion.

Pericarditis and Endocarditis.—Dr. JOSEPH COATS showed a specimen of pericarditis, in which, with very marked redness of the membrane, there was a layer of soft lymph on the surface, having the usual shaggy appearance. In the same case, there was acute endocarditis affecting the aortic valve chiefly, one of the semilunar folds of which was perforated by a round aperture, about one-eighth of an inch in diameter.

MEDICO CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, FEBRUARY 3RD, 1875.

RUTHERFORD HALDANE, M.D., President, in the Chair.

Exhibition of Patients, Specimens, etc.—Dr. P. H. WATSON showed a girl, whose wrist he had excised, including the whole Carpus and Base of the Metacarpus, six months ago, by a single linear incision on the radial side of the dorsum of the hand. The result was admirable.

Dr. FINLAY showed a boy, who had suffered from Suppurating Inguinal Glands for sixteen months, which speedily healed up, after the removal of an ingrowing toe-nail.

Dr. FINLAY also showed a case of Forked Uvula.

Dr. WATSON showed an Urethrotome for Internal Division of Stricture. The knife is protruded, acting upon a conducting rod in the thick part of the instrument, which in shape resembles a Syme's staff, from which a slender tenotomy-knife projects, which divides the stricture from behind forwards as the instrument is withdrawn.

Dr. WATSON also showed some interesting specimens: one of proliferating cyst of the mamma; of sarcoma of scalp; of diseased wrist-joint; and an intracapsular fracture of the neck of the femur in an aged female, who had died somewhat suddenly from pulmonary embolism.

Dr. LITTLEJOHN showed a specimen of Rupture of the Heart. A man fell accidentally from the roof of one of the tallest houses in the Old Town of Edinburgh, eight storeys, and was killed on the spot. The only external mark of injury was a laceration of the scalp in the centre of the forehead. The cranium was intact, and the brain, with the exception of slight subarachnoid effusion of blood, presented a normal appearance. The right cavity of the chest contained several pints of fluid blood, which had escaped from several apertures in the right auricle. There was universal adhesion of the pericardium from old standing inflammation. The heart and aorta were of normal size, and the cardiac substance was microscopically healthy. The liver was slightly ruptured on its under surface. The cavity of the pelvis contained about a pint of fluid blood, which had apparently come from a wound of the iliac vein, the result of a detached portion of the side of the sacrum being driven against it. There were no other injuries.

Dr. LITTLEJOHN also showed the windpipe and a portion of the skin of the neck, from a case of Suicide by Hanging. The dark parchment like appearance of the furrow, caused by the pressure of the ligature, was well seen, although the ligature employed was a soft cotton handkerchief. The skin on the thyroid cartilage showed a marked cicatrix, the remains of a suicidal wound inflicted seven years previously. Internally, the reparation of the wound was most complete, there being scarcely any vestige of a cicatrix.

Mr. JOSEPH BELL showed a specimen of Epithelioma, which he had removed from the lip of an aged female in the usual manner. He stated this was the seventh case of a similar nature on which he had operated in females, and that all of the patients were smokers.

Mr. J. BELL also showed two Incisor Teeth and a Gold Plate with hooks on it, which had been swallowed during sleep, after nearly suffocating their owner. He had managed to feel them in the stomach by a probang, but ordered bulky indigestible food, kept the bowels constipated for some days, and they passed without any trouble on the seventh day.

Dr. HALDANE showed a specimen of Calcification of the Gall-bladder. The patient, aged 53, was ascitic on admission; and soon required tapping. She died in a week. Numerous hard masses which had been felt after the tapping were found to be cancer of the peritoneum and omentum.

Mr. T. ANNANDALE showed the fragments of an Os Calcis, which he had removed from the foot of a patient, who had fallen forty feet upon his heel, and sustained no other injury.

Mr. ANNANDALE also showed an example of Rupture of the Ligamentum Patellæ, the result of a violent twist in a railway accident.

Mr. ANNANDALE also showed the parts removed in Excision of the Elbow-joint, in a case of Unreduced Dislocation of both bones of the forearm.

Cancer of the Ovary.—Dr. FOULIS read a paper on cancer of the ovary. After noticing the researches of Waldeyer of Breslau on the development of the ovum and ova, he stated as his conclusion that the ova and epithelial lining of the Graafian vesicles were derived from the germinal epithelium on the surface of the ovary. He then described his own investigations on the same subject, and indicated where they coincided with, or differed from, those of Waldeyer. By means of careful microscopic research, he had shown that the epithelial lining of the Graafian vesicles was formed from the connective-tissue-corpuscles of the stroma. He regarded each Graafian vesicle as a cystic formation, the overdistension of which was the beginning of an ovarian tumour, and the excessive proliferation of their epithelial lining as the cause and explanation of their frequent malignancy. He then gave an account of two cases of ovarian tumour, which had been under the care of Dr. Thomas Keith. In the first case, tapping was necessary, and a large quantity of ascitic fluid was drawn off. In this fluid, Dr. Foulis detected, among other things, a large quantity of proliferating epithelial cells. The operation of ovariectomy proved that the case was one of malignant disease, with numerous adhesions. The second case was similar. The ascitic fluid, drawn off on two occasions, showed enormous quantities of similar proliferating epithelial cells, from which, aided by the experience of his former case, Dr. Foulis predicted malignancy; and, though the patient was, in other respects, in good condition, Dr. Keith did not operate. On her death, some time afterwards, the *post mortem* examination showed that extensive malignant disease existed. Dr. Foulis pointed out that the detection of masses of proliferating epithelial cells in large quantity in ovarian or ascitic fluid seemed to afford satisfactory evidence of the existence of malignant disease.—The PRESIDENT, in thanking Dr. Foulis for his paper, described it as an important addition to our knowledge of the diagnosis of malignant growths, as a valuable contribution from physiology to pathology, and an admirable illustration of the doctrine of the inoculability of tubercle and cancer.—Dr. MATTHEWS DUNCAN recalled a discussion on this same subject, the diagnosis of ovarian tumours, in which Dr. Handyside, Professor Simpson, Professor Spence, and Professor Bennett took part. He alluded to Spiegelberg's researches in the subject of the diagnosis between ovarian fluid and that of chronic peritonitis, and the unsuccessful result of them. He alluded to the difficulty of the question, and the necessity of further observation; but believed that the relation of the masses of epithelial cells found free in the peritoneal fluid, was a new observation, and one of great value in diagnosis.—Dr. GRAINGER STEWART and Mr. CHENE continued the discussion, and Dr. FOULIS briefly replied.

CORRESPONDENCE.

THE CONTAGIOUS DISEASES ACTS.

SIR,—I see I was too sanguine in hoping that any figures could convert Dr. Nevins, and I shall only ask for a few lines to reply to his arrangement of the Royal Engineer Statistics in his letter in your JOURNAL of February 13th, for his other statements may safely be left to themselves.

Among the Engineers, Dr. Nevins says, "Primary syphilis had fallen before the Acts from 108.3 to 74.8 per 1,000, or one-third of its amount in six years, *i.e.*, above five per 1,000 yearly". In this statement it is implied that the fall had been from year to year, and that it was permanent. Now, the ratios per 1,000 for these six years (1860-65) are 108.3, 77.9, 109.3, 107.6, 82.0, 74.8; *i.e.*, there were, as usual, both falls and rises, from year to year, but there was no continuous decline. Between 1860 and 1865, taken as single years, there was, as Dr. Nevins says, a fall of thirty-three per 1,000, but, if he had taken the years 1861 and 1865, he would have found the difference to be only three per 1,000. If he had taken 1861 and 1862, he would have found a rise of thirty-one per 1,000. In fact, in such questions we cannot properly select single years at pleasure for comparison, and conclude as to rise or fall of admission for other years; we must take groups of years to neutralise the fluctuations.

Having thus erroneously implied that the ratio 74.8 was the lowest number of a continually declining series, and entirely neglecting the fluctuations, Dr. Nevins compares this ratio of a single year with the *mean* of the next three years (1866-68), when the Acts were in partial operation. In these three years, though there were fluctuations which bring the mean above the *lowest* ratio of the preceding six years, yet this mean was far below that of the six years before the Acts, and below the means of the first three, or the last three years of the six. To compare the mean of a fluctuating series with the ratio of a single year, is a mode which I should have thought no one conversant with figures would have adopted.

Passing to the six years (1869-74) when the Acts were in full operation, Dr. Nevins selects the highest ratio in these six years, viz., seventy-six per 1,000 in 1871, and affirms that it was "thirteen per 1,000 higher than before the Act was in full operation". I was at first puzzled to see how he got this number thirteen, for the ratio of seventy-six per 1,000 (which was the *highest* in six years after the Acts) is only 1.2 per 1,000 higher than the *lowest* ratio (74.8) in the six years before the Acts. But I see he has got it by selecting the year 1868, when the Act was in partial operation, and when the ratio was 63.2, for comparison with 1871. Here, again, he neglects all the fluctuations, and never notices the fact that, if 76 is a higher ratio than 63.2, there are yet several much lower ratios than 63.2 in the years influenced by the Acts. The figures only entitle him to say that in a particular year, under the complete Acts, the ratio was thirteen to 1,000 higher than in a particular year under the partial operation of the Acts; but his expression conveys far more than this. His method is a sort of unnatural selection, by which he secures the survival of the fittest for his purpose. It may answer for those who will not refer to the figures for themselves, but for those who will look, the fallacy of his plan must be at once detected.

It would take up too much space to make a similar analysis of the statements on gonorrhœa, but the error of the method is the same.

With regard to the ratios per 1,000 of primary syphilis and gonorrhœa in the home army for 1861, 1866, and 1872, to which he refers me, I cannot make my numbers agree with his; but this is of little consequence. He here again selects years, makes no account of fluctuations of intervening years, and in the last year to which he refers (1872) makes confusion worse confounded by taking the whole army, and therefore concealing the statistics of the protected stations by mixing them with those of the unprotected, and then arguing from this "incompatible mixture" for the failure of the Acts.

I may also add that he has made a wrong quotation, or, at the very least, would lead his readers to a wrong inference, from the fifty-fifth section of the Report of the Royal Commission.—I am, Sir,

Netley, February 24th, 1875.

E. A. PARKES, M.D.

P.S.—There is a slight misprint in my letter on the above Acts in the JOURNAL of Feb. 20th. The number of non-commissioned officers and men in the 58th Regiment who are married with leave is forty-four, and not fifty-four, as given in the letter. I was afraid of occupying too much space, or I should have pointed out that, if the numbers of married men in the two regiments are deducted from the mean strength, the calculation of syphilitic and gonorrhœal admissions becomes still more adverse to the 106th Regiment in the unprotected stations.

SIR,—Your paper of the 13th instant contains a letter from Dr. Nevins, wherein he says, with reference to the arrangement of the stations, adopted in the returns of primary venereal affections from the Army Medical Department, "The fatal objections to clubbing 'the stations under the Acts' together, and 'those not under the Acts,' are fully shown in my statement to the Home Secretary: and, as these objections have not yet been answered, it is useless to discuss the question on that basis". Dr. Nevins is under a misapprehension here; and I beg to refer him, and such of your readers as may be interested in the subject, to the *Medical Times and Gazette* of 26th December last, where they may see, at page 706, not only that there is no ground for Dr. Nevins's criticism, but that the illustration he himself gives, when written out, is at variance with his own rule.

It will be seen also that the comparison between the frequency of primary venereal sores at the stations now "under the Act", and what it was before they came under the Act, has there been made, as far as the published returns would admit; though the stations have not been taken singly, but all those which came under the Act the same year were put together, for the double purpose of neutralising minor fluctuations of the description noticed in the paper, and of rendering the table clearer to general readers.

The opponents of the Contagious Diseases Acts lay great stress on the reduction of primary sores from 1860 to 1866, and argue as if that should have gone on without check. There is not the slightest support for this position. The only data as to the frequency of primary venereal sores available for comparison with those since 1860 are contained in the statistical reports on the health of the cavalry and Foot Guards at home between 1830 and 1846; and these present fluctuations similar in character and extent to those found at the stations "not under the Acts" since 1860.

ROBERT LAWSON, Inspector-General of Hospitals.

February 1875.

SIR,—To those of your readers who may have taken an interest in the

correspondence which has been published from time to time in the BRITISH MEDICAL JOURNAL on the influence of the Contagious Diseases Acts in diminishing disease, or otherwise, the following facts may prove of some value, in addition to those brought forward by Drs. Parkes and Myers, as I can vouch for their accuracy, having been present with the regiment during the whole period under consideration.

The 50th Regiment arrived at Colchester from Aldershot on September 16th, 1872, and remained at that station till July 3rd, 1874, when it was again moved to Aldershot, to take part in the "summer drills", after which it embarked for Ireland, and arrived in Dublin on August 5th, where it has been stationed up to the present date.

The following table shows the total number of admissions into hospital at Colchester and Aldershot from January 1st, 1873, to August 7th, 1874: both stations are under the Acts.

Year.	Average Strength.	Gonorrhœa	Primary Syphilis.	Recruits who joined in Year.
1873	655½	43	19	53
1874 (7 months)	573	24	4	44
		67	23	97

Out of the above number, there were seven cases of gonorrhœa and seven of primary syphilis, which were contracted in places not under the operation of the Acts, and ought not in fairness to be included in the above figures.

Let us now see what effect a residence of six and a half months in Dublin has had on the health of the regiment. The result is given in the following table.

Year.	Average Strength.	Gonorrhœa.	Primary Syphilis.	Recruits who joined in Year.
1874 (5 months)	550	15	25	Nil.
1875 (1½ ")	517	10	10	Nil.
		25	35	Nil.

Any person curious on averages may easily work them out from the data already given; I simply confine myself to a bare statement of facts, and from them I have no doubt what will be the opinion of every person whose mind is not already biased by a foregone conclusion. It has been stated that the operation of Clause 126 of the Royal Warrant, dated September 26th, 1873, has rendered the Army Returns of little use, in consequence of the men concealing their disease; that argument does not hold good with respect to the above returns, as the clause was in force from October 1st, 1873, to the present time, and a comparison of the first half of the year 1874 with the latter will show that the admissions for primary syphilis in Dublin was six times more numerous than at Colchester. Every medical officer in the Army with whom I have served has remarked to me the mildness of the disease in the protected districts in comparison with the unprotected, and this has been my own experience.

It is the duty of every member of our profession to weigh well the arguments and facts set forth on each side of the question, before lending the influence and weight of his name to those who are determined on repealing the Acts at all hazards.

I am, sir, your obedient servant.

N. FOLLITT, Surgeon-Major, 50th Regiment.

Dublin, February 22nd, 1875.

SIR,—It is now nearly two years since Mr. Fowler brought in his Bill for the repeal of these useful and excellent Acts, which Bill, however, was rejected by a very large majority. Much to the surprise and regret of many, the task of moving the amendment was not undertaken by the late Government (though a Royal Commission had reported favourably on the Acts), but was left to a private member.

As it is very desirable that a different course should be pursued when Sir Harcourt Johnstone's Bill comes forward for second reading in June next, I would suggest that a circular memorial in favour of the Acts be forwarded to every member of the British Medical Association, and that the memorial, when completed, should be forwarded to the Home Secretary. I have not the slightest doubt that several thousand signatures will be obtained, and that other memorials from those who are not associates will follow. Fortified with such an expression of opinion from the great body of medical practitioners throughout the country, I feel sure that the present Government will come forward in defence of these much abused Acts, and that the duty of moving an amendment to Sir H. Johnstone's Bill will be undertaken by a Cabinet minister.

Among the members of our profession, the opponents of the Acts are really very few in number, though, from the peculiar tactics of the party to whom they have allied themselves, their number has been made to appear much larger. A very much larger number of our pro-

professional brethren would be glad to see the Acts extended to the civil population: many others, not ready to go quite so far as this, would be very sorry to see them repealed; while a certain proportion have been hitherto indifferent. The admirable letters of Dr. E. A. Parkes, and those of Surgeon-Major Gore and others, have gone very far to remove this indifference, as well as to convince all who are capable of conviction that the Acts have been instrumental in reducing disease; while the able leaders which have appeared in your columns have shown conclusively that they have been equally beneficial in a social and moral point of view.

Why Liverpool should be the great stronghold of the opponents of these Acts, I cannot conceive. It would be very easy to give numerous and weighty reasons why, on the contrary, this should be the next town to which the benefits of the Acts should be extended. This would occupy too much of your space now, though I trust, in a future issue, you will permit me to do so. For the present, it will suffice to quote the words of Mr. J. D. Lewis (the late member for Devonport, when seconding the amendment to Mr. Fowler's Bill), which seem to me very appropriate: the italics are mine. "Sir, in conclusion, let me assure the House that the agitation on this subject is slowly, but surely, dying out. *It was always loudest, or, perhaps, I should rather say shrillest, in proportion to the distance of the persons who raised it and the localities where they lived from the places where the Acts were practically known and appreciated.* It was never greater than that which was raised against vaccination on its first introduction by old women of both sexes. But the House of Commons of that day stood firm, and I trust that the House of Commons of this day will stand equally firm, and not proceed to decree the unrestricted circulation of venereal poison to the detriment of posterity, whose curses we should incur, and, what is worse, we should merit. I trust there will be no successful effort to tamper with these Acts, which, in localities where they have been in force, have done more in a few short years to alleviate one of the most frightful scourges which can afflict humanity, to improve the condition of the towns, *to eradicate juvenile prostitution, to bring to bear a moral influence on the unfortunate women who are subject to them,* than all the voluntary efforts of all the philanthropists who have ever existed."

The "last expiring shriek" is proverbially loud; hence, perhaps, the recent agitation in Liverpool and elsewhere.

I am, yours faithfully, FREDERICK W. LOWNDES.

Liverpool, February 20th, 1875.

SIR,—In the JOURNAL of January 23rd, it is stated that "nearly the entire staff of the medical school" of this town signed a memorial in favour of the retention of the Contagious Diseases Acts in seventeen garrison towns and ports, the fact being, that five of the lecturers, or more than one-third of the entire staff, did not sign. All these gentlemen have been consulted, and they all concur in the opinion that the statement was not warranted by the fact, and that, in justice to them, it should be corrected. I am, sir, yours faithfully,

WILLIAM CARTER, M.B., Lecturer on Botany.

74, Rodney Street, Liverpool, February 21st, 1875.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Friday, February 19th, 1875.

Adulteration of Food and Drugs Bill.—MR. SCLATER-BOOOTH moved the second reading of this Bill. After some preliminary remarks, he said that the measure was framed in five parts. It described the offences, and lays down rules for the appointment and duties of analysts; it had some provision with regard to expenses, important clauses having reference to some new duties imposed on customers, and it prohibited the sale of articles not of the nature, substance, and quality demanded by the purchaser, with certain exceptions, viz., "Where any matter is mixed therewith for the purpose of rendering it portable or of preserving it; where a harmless ingredient is mixed with it for the purpose of rendering it palatable or of improving its appearance; where, according to the usage of trade, it is sold in a mixed state; where it is the subject of a patent in force, and is supplied in the state required by the specification of the patent; where British, colonial, or foreign spirits are reduced from their ordinary strength by persons licensed and paying rates under the Excise; where a drug is compounded rather in conformity with the prescription of a registered medical practitioner, or otherwise, according to the usage of trade; where the article is unavoidably mixed with some extraneous matter." A new provision had been added, making it an offence where any property was abstracted from an article that affected its quality, as well as by the mixture of others deleterious

to it, provided that if the articles were mixed in proper proportions for the convenience of all parties, the retailers would not be required to declare the same orally to the customer, but he would have to attach a proper label to the mixed article, which would relieve him from the penalty. The appointment of analyst would rest with the local authorities, and it would only be compulsory when the Local Government Board called upon them to make such appointment. Power would be given to districts to join in the appointment of one analyst for the whole. A refusal to allow samples to be taken for analysis would be a punishable offence, and the certificate of the analyst was to be *prima facie* evidence of the charge, the obligation of showing that it could not be supported being upon the defendant. Clause 25, providing for the discharge of the defendant under certain circumstances, had been very carefully prepared. It was as follows:—"If the defendant in any prosecution under this Act prove to the satisfaction of the justices or court that he sold the article in the same state as when he himself purchased it, and that he bought it as the same article in nature, substance, and quality as that demanded of him, and with a warranty in writing to that effect, he shall be discharged from the prosecution." A clause had been added, making it a duty of the Customs to examine, and, if necessary, to analyse articles of food brought from abroad. One half of the controversies under the Act had arisen in regard to importations alleged by the defendants to have been adulterated abroad. It was obvious that in some cases the retail and wholesale dealer, or the importer, might be innocent, except so far as they had been culpably negligent, and he believed this provision would meet the difficulty. The select Committee had been of opinion that an investigation by the Customs would, in a short time, put an end to the adulteration of tea. Perhaps this expectation was too sanguine, but he felt sure the adulteration of tea would, by these means, be much diminished. It was provided that the analyst should not appear as a witness unless expressly desired to do so; and that samples of adulterated articles might be sent through the post under regulations prescribed by the Postmaster-General.—MR. SANDFORD suggested that the number of analysts who were to be appointed, as at present, should be reduced. The Bill rather favoured wholesale dealers, on whom ought to rest the responsibility for introducing an adulterated article.—MR. MUNTZ hoped the Bill would be made to extend to Ireland and Scotland, and regretted that there was no provision for preserving the purity of wine. There were other articles than tea which could be examined with advantage upon importation.—MR. PELL, MR. WHITWELL, SIR H. W. PEEK, and other hon. gentlemen suggested various amendments which might be made in committee, but at the same time expressed a general approval of the measure of the Government.—DR. PLAYFAIR was afraid the Bill required very serious alteration in committee if it were to be beneficial. It abolished the Acts of 1860, 1867, and 1872, which had produced great effects in favour of the public. Those Acts had prevented the adulteration of milk, and compelled the sale of pure bread. The present Bill, however, was defective in several important respects. It gave a definition of food, from which coffee and tea were excluded. In the previous Acts it was assumed that the persons selling any article ought to know whether it was pure; but the present Bill was to be regulated by ignorance rather than by knowledge, for a man was only to be punished if he knowingly sold an adulterated article, and that word "knowingly" would neutralise, to a very great extent, the public advantage to be gained under the Bill. Then the usages of trade were allowed to be set up under the Bill, and that would enable any dealer to drive a coach and four through its provisions; for the usages of trade allowed the adulteration of drugs, the mixing of oil of vitriol with vinegar, the putting of alum in bread, and the addition to milk of 21 per cent. of water. He also objected to the provisions of the Bill which related to analysts, as they would lead to the appointment of a large number of inefficient analysts, instead of the appointment of a few competent ones with good salaries.—MR. MUNDRELLA believed the Bill would be effective for the purpose intended—namely, the protection of the public—and that it would, at the same time, get rid of many of the vexatious restrictions which had been imposed on the retail trader.—MR. RAMSAY suggested that the right hon. gentleman who had charge of the Bill should explain to the House in Committee the means by which the scientific knowledge and attainments of the gentlemen appointed as analysts were to be determined. The analysis of organic substances was not a subject on which chemists themselves were agreed, nor were they agreed as to the tests to be employed for finding any particular substance in any particular combination.—MR. YEAMAN hoped that the Bill would be extended to Scotland.—After a few words from MR. SCLATER-BOOOTH in reply, the Bill was read a second time, and ordered for Committee on Thursday, March 4.

Monday, February 22nd.

Water-Supply.—MR. SCLATER-BOOOTH, in reply to Mr. P. A. Taylor,

in reference to a statement made by Dr. Sandwith, that at a large west-end club the drinking-water supplied by a certain water company left such abundant deposits of mud in the cisterns that it was necessary frequently to clean them; and that this mud was found by an eminent analyst to consist of various unwholesome *débris* and of human excrement, said that the statement referred to attracted his attention, and he had since had frequent communications on the subject with the water examiner of the metropolis. He was not in a position to make a statement of a reassuring character to those who did not attend to their cisterns, pipes, and boilers, within their own houses; but, according to the analyst, the company that supplied the water had been supplying good wholesome water during the last month, and was continuing to do so. Before this statement, great complaints had been made against the same company, but the water supplied by them was peculiarly liable to pollution during a flood. From the action he felt it his duty to take, the company had prepared a private bill, which was now before the House, by which they intended to take powers so as to greatly improve their machinery, and construct large reservoirs of an expensive character, which would have been done two years ago, had not the bill been thrown out on the second reading.

Scotch Lunacy Grants.—In reply to Mr. Ramsay, the CHANCELLOR OF THE EXCHEQUER said that it was intended to make the Scotch Lunacy Grant applicable to all patients who are subject to, and under the inspection of, the General Board of Lunacy, with two qualifications: 1. That the lunatic shall have been sent to an asylum or lunatic ward of a workhouse, etc., under orders of the Lunacy Board, and (2) that the lunatic is charged upon the parochial rates.

Wednesday, February 24th.

The Canal Population.—Mr. CROSS, in answer to Mr. W. Price, said his attention, he was sorry to say, had been called to the very sad condition, with regard both to sanitary matters and the education of what might be called the floating population on the canals of this country. As these children were not engaged in any workshop or labour affected by the Workshops Acts, there would be some difficulty in including them under the commission, but he would take some other means to inquire into their exact condition.

Second Readings.—The second readings of the following bills have been fixed for the days mentioned:—Agricultural Labourers' Dwellings (Ireland) Bill (Mr. Bruen), Wednesday, March 10; Contagious Diseases Acts Repeal (Sir Harcourt Johnstone), Wednesday, June 23rd; Coroners (Ireland), (Mr. Vance), Wednesday, May 12th; Infanticide (Mr. Charley), Wednesday, May 12th; Labourers' Cottages, etc. (Scotland) (Mr. Fordyce), Wednesday, May 26th; Universities of Scotland: Degrees to Women (Mr. Cowper-Temple), Wednesday, March 3rd.

Committees.—Artisans' Dwellings Bill (March 4th); Adulteration of Food and Drugs Bill (March 4th).

disappointment. His sanguine temperament has just been wounded by the *long froid* with which the Dronfield Local Board treat his reports of the unsanitary condition of their town, and frustrate his efforts to lift its inhabitants from the slough of despond in which they are wallowing. In a letter read at the board meeting on Wednesday evening, he says, 'I have to-day visited various places in the district of Dronfield, and, greatly to my disappointment, found none of the thirty nuisances reported to you November 2nd, 1874, were either abolished or abated, though some of them are of a serious nature, and cannot fail to prove more or less injurious to the inhabitants surrounding them. I would again impress upon you the importance of strictly enforcing the provisions of the sanitary Acts as to nuisances; otherwise, it will be my duty to make a special report of the unsanitary condition of your district to the Local Government Board'. It is not one of the failings of the public bodies in Dronfield to be too precipitate about making improvements. Most people would suppose, however, that the threat of being reported to head-quarters would have led to some definite steps being taken, in order to make up for lost time; but, if Dr. Mackintosh cherished such a hope, he is again doomed to disappointment. Instead of the officer of the board being ordered to take out summonses against the offenders, the report was shelved, with the usual understanding that the officers would be as strict as possible, or, in other words, that matters will remain as they are until the Local Government Board interferes."

POOR-LAW MEDICAL APPOINTMENTS.

ALDRICH, Frederick E., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the No. 7 District of the Thangoe Union, Suffolk, *vice* F. G. Lawrence, M.R.C.S. Eng., resigned.
BASTABLE, Daniel H., L.K.Q.C.P.I., appointed Medical Officer for the South District of the Poplar Union, *vice* J. Sarjant, L.R.C.P. Ed., resigned.
BRUMWELL, George W., L.R.C.P. Ed., appointed Medical Officer for the Southwatering District of the Kendal Union, *vice* John T. Brumwell, M.R.C.S. Eng., resigned.
CRESSWELL, Thomas H., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Maresfield District of the Uckfield Union, *vice* S. Brown, L.R.C.P. Ed., deceased.

APPOINTMENTS OF CONSULTING MEDICAL OFFICERS OF HEALTH IN IRELAND.

BROWNE, Samuel, L.K.Q.C.P.I., appointed Consulting Sanitary Officer for the Belfast Urban Sanitary District.
CREAN, Charles E., L.K.Q.C.P.I., appointed Consulting Sanitary Officer for the Claremorris Rural Sanitary District.
DAVIS, Hugh A., M.D., appointed Consulting Sanitary Officer for the Newport Rural Sanitary District.
FALKNER, Frederick J., M.B., appointed Consulting Sanitary Officer for the Naas Rural Sanitary District.
FALVEY, Francis Joseph, L.R.C.P. Ed., appointed Consulting Sanitary Officer for the Tralee Rural Sanitary District.
KELLY, Dillon, M.R.C.S. Eng., appointed Consulting Sanitary Officer for the Mullingar Rural Sanitary District.

MILITARY AND NAVAL MEDICAL SERVICES.

THE ARMY MEDICAL DEPARTMENT.

SIR,—The officers of the department must agree with the opinion expressed in your leader of the 6th, that some definite statement of what they require should be made. It is almost impossible to do this owing to existing regulations and conditions; but, if one can form an opinion from the numerous communications to the press, pamphlets, etc., one cannot fail to be struck with the fact, that the majority of the writers are against the so-called "unification". The following points seem to embrace briefly the views of a large number of writers.

1. The restoration of the Royal Warrant of October 1858, with such increase of pay, half-pay, and retirement, as may be deemed fair, considering the decreasing value of money. (Various scales are mentioned.)

2. Restoration of the old regimental and staff system, and as far as practicable, the restoration to their regiments of all medical officers removed therefrom, who have not since been promoted. (Various opinions about army hospital corps, compounders, etc.)

3. A fixed and easily ascertainable scale of allowances, subject to one interpretation only.

4. Promotion to the rank of surgeon-major after the completion of twelve years' service, as in the Indian service, or previously for merit.

5. Compulsory retirement of surgeons-general after five years in that rank. Appointment to director-general to be made by selection from the ranks of surgeon-general, whether on full or half-pay.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE Medical Officer of Health for Neath, Mr. E. R. Morgan, is determined that the provisions of the Sanitary Act shall be thoroughly comprehended in the district under his care, by having plain instructions of a sanitary nature printed in English and Welsh for gratuitous distribution. In adopting this plan, Mr. Morgan has shown that he at least thoroughly understands the *Cymry* and their requirements.

THE Sculcoates Board of Guardians have increased the salary of Mr. W. Holder, medical officer for the Sutton district, from £60 to £100 per annum.

THE Bedford Rural Sanitary District has hitherto been divided, and held by two medical officers of health at £120 per annum each; but upon the recent death of Mr. Stedman, the officer for the northern sub-district, it was determined to appoint one officer for the whole district, at £210 per annum; and it was intimated at the last meeting of the authority, that Dr. Prior, whose appointment as officer for the southern sub-district would expire on March 25th, would be willing to undertake the duties.

SANITARY INERTIA.

A CORRESPONDENT of the *Sheffield and Rotherham Independent* of February 6th writes: "Dr. Mackintosh is not one of those blessed individuals who expect nothing, and are consequently spared the pain of

6. Staff appointments, such as professorships at Netley, secretaries of Branches at War Office, etc., to be held like similar appointments amongst combatant officers, for a period not exceeding five years.
7. Compulsory retirement of all ranks at sixty years of age.
8. Removals of present restrictions as to leave, sick leave, etc.
9. Amalgamation of the Indian and British medical services: or, at least, a fair share of the medical appointments in that country, as combatant officers have of the military appointments.
10. Relative rank of administrative officers, as in the Control.

I am, Sir, your obedient servant,
DISESTABLISHED.

THE ARMY MEDICAL SERVICE.

SIR,—Allow me, in continuation of a previous letter, an extract from which you kindly published in your JOURNAL of February 14th, 1874, again to draw your attention, and that of the profession, to the continued diminution of the Army Medical Department. By the *Army List* of January last (in which are several errors), it will be seen that there are 2 administrative and 38 executive officers less than in January last year, and 176 executive officers less than in January 1869—a steady decrease of nearly 30 *per annum*.

Might not this be urged as a plea for quicker promotion—say, at twelve years' service—as the decrease, and consequent saving of expenditure, is almost entirely in the junior ranks?

On April 14th next, there will be about one hundred surgeons who have completed twelve years' service; and, as recent promotion has been at the rate of one *per mensem*, it cannot be said that an acceleration is not wanted. The pay of thirty-eight surgeons, at the average of the various rates, according to length of service (13s. 9d.) would be £26 2s. 6d. *per diem*—increase of 2s. 6d. in pay and 1s. 6d. in allowances *per diem* above previous rates; to one hundred surgeons-major, would be £20—a considerable balance in favour of the State on the transaction. Or let the money be expended in giving a better retirement to our seniors, and thereby quicken promotion indirectly, and make us bear with more equanimity the increased burdens of our present mongrel system.

February 1875.

Yours, etc., A. M. D.

OBITUARY.

JOHN ROBERT TRAIL, M.D., MONYMUSK.

DR. TRAIL died at Aberdeen on February 12th, at the age of fifty-six. He was born at Uduy in Aberdeenshire, and educated at the school there, which then enjoyed a high reputation amongst the education institutions of the north of Scotland. At King's College and University Aberdeen, he gained by competition a high bursary or exhibition; passed with distinction through the Arts' Faculty; and took the degree of A.M. in 1835. He subsequently pursued his medical studies, partly in Aberdeen and partly in Edinburgh, where he obtained the degree of M.D. of the University, and the diploma of the Royal College of Surgeons, and settled in practice at Monymusk, a thriving agricultural district of his native county. Dr. Trail was known as a highly accomplished and successful practitioner, and speedily secured for himself the esteem and confidence of his numerous patients, while his co-operation was much sought after and highly valued by his professional brethren. He took a deep and intelligent interest in agricultural matters. Last year, he resigned the post of Extra-Academical Examiner in Aberdeen University, after holding it for three years.

Though, till within the last three months of active habits, Dr. Trail had long suffered from an affection of the heart, the foundation of which had been laid by rheumatic fever while engaged in his medical studies at Aberdeen. His funeral was attended by a large concourse of friends and patients, along with several members of "The Garrioch and Northern Medical Association".

PRESENTATION.—A deputation of the inhabitants of the Auchtergaven district, Perthshire, on the 9th instant, presented to Dr. Yeats, as a mark of their respect and esteem, a splendid brown mare pony, fully accoutred with saddle and bridle, and every other necessary, along with a purse of sovereigns. Dr. Yeats then proposed, "The Agricultural Interests of the District", coupled with Mr. Paton, as a specimen of one of our most enterprising farmers, and Mr. Paton replied in a short speech. The Doctor next proposed, "The Interests of the Village of Bankfoot", coupled with Mr. McKenzie, who replied. Mr. Paton proposed, "Mr. John Murray", who made a suitable reply. The proceedings of a very pleasant evening were then brought to a conclusion.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Licentiates on February 20th, 1875.

Davies, John William, Ebbw Vale, Monmouthshire
Frost, William Adams, 47, Ladbroke Square
Hardman, William, Blackpool
Lyons, Alfred de Courcy, 15, Vicarage Gardens
Mason, Henry William, 19, Granville Square
Stocker, Charles Joseph, Stratford Green
Thomas, Robert Thomas, 34, Great Percy Street

The following candidates, having passed in Medicine and Midwifery, will receive the College License on obtaining a qualification in Surgery recognised by this College.

Edwards, David, University College Hospital

APOTHECARIES' HALL OF IRELAND.—At the professional examinations, held in January 1875, the following gentlemen obtained the licence to practise Medicine and Pharmacy.

John Moore Nichols and George Michael Cuffe.

At the examination in Arts, the following passed.

Patrick Joseph Beland, Benjamin Burland, Matthias Butler, Michael Joseph Cohen, John Donaldson, John Joseph Hayes, Patrick Joseph Leinham, Richard Michael Ralph, James O'Dwyer, and Charles Wall.

UNIVERSITY OF DUBLIN: Hilary Term, 1875.—At the examination for the Degree of Bachelor of Medicine, held on Tuesday and Wednesday, February 2nd and 3rd, the candidates passed in the following order of merit.

MacDowel, Effingham Carroll	Erskine, John
Doyle, Bernard	Blood, Joseph
Moran, James J.	Carleton, Arthur W.
Robinson, Leland	Irwin, John A.
Fleming, Hans B.	Hughes, George A.
Banks, Alfred	Stanley, William H. R.
White, Patrick Henry	

At the examination for the Degree of Master in Surgery, held on Friday and Saturday, February 5th and 6th, the successful candidates were placed in the following order.

MacDowel, Effingham C.	Blood, Joseph
Carleton, Arthur	Blood, Matthews
Doyle, Bernard	Tasffe, Robert
Farrell, Peter J.	Pollen, Henry

In consequence of having obtained double First Place, Mr. MacDowel was recommended to receive the Degree of M.Ch. *stipendiis condonatis*.

MEDICAL VACANCIES.

THE following vacancies are announced:—

ALDERBURY UNION—Medical Officer for the Fourth District and the Workhouse.

BARONY PAROCHIAL HOSPITAL, Barnhill, Glasgow—Dispenser.

BECKETT HOSPITAL AND DISPENSARY, Barnsley—House-Surgeon.

Salary, £140 per annum, with furnished rooms, gas, and coals.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN—Resident Medical Officer. Salary, £80 per annum, with board, washing, and attendance. Applications to be sent in not later than March 3rd.

BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.

BRAMPTON UNION—Medical Officer for the Union and Workhouse. Salary, £50 per annum, and extras, £31 15s.

CLINICAL HOSPITAL AND DISPENSARY FOR CHILDREN, Manchester—House-Surgeon. Salary, £60 per annum, with board and residence. Applications to be made on or before March 6th.

COVENTRY AND WARWICKSHIRE HOSPITAL—House-Surgeon and Dispenser. Salary, £100 per annum, with board, lodging, and attendance. Applications to be made on or before March 25th.

DERRYSHIRE GENERAL INFIRMARY—Assistant House-Surgeon. Board, lodging, and washing, but no salary. Applications to Secretary.

DORSET COUNTY HOSPITAL—House-Surgeon. Salary, £70 per annum, with £10 additional as Secretary. Applications to be made on or before March 18th.

DOVER UNION—Medical Officer for the St. Mary's District and the Workhouse. Salary, £180 per annum.

DURHAM COUNTY ASYLUM—Assistant Medical Officer.

FLEX MILLS FRIENDLY SOCIETY—Medical Officer. Salary, £110 per annum. Applications to A. McKeeman, 7, Hunston Square, Johnstone, N.B.

GRANTHAM UNION—Medical Officer for the Ropsley District. Salary, £26 10s per annum.

HAILSHAM UNION—Medical Officer and Public Vaccinator for the Parish of Heathfield. Salary, £44 per annum, and fees. Applications to be made on or before March 8th.

HARRIS, Parochial Board of Surgeon. Salary, £66 per annum, including vaccination and medicine for the poor. The gentleman elected will get £90 per annum for attending the ratepayers and cottars within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.

HEADINGTON UNION—Medical Officer for the Wheatley District. Salary, £70 per annum.

HENDON UNION—Medical Officer for the Willesden District. Salary, £40 per annum.

HOSPITAL FOR WOMEN, Soho Square—Physician and two Assistant-Physicians. Applications to be sent in on or before March 2nd.

KILBURN DISPENSARY—Senior Resident Medical Officer. Salary, £120 per annum, with apartments, coals, gas, and attendance. Applications to be made on or before March 8th.—Assistant Resident Medical Officer. Salary, £80 per annum, with apartments.

LANGPORT UNION—Medical Officer for the Babery District. Salary, £27 per annum, and fees. Applications to be made on or before March 2nd.

LONDON FEVER HOSPITAL—Resident Medical Officer. Salary, £300 per annum, with residence, coals, gas, and attendance. Applications to be made on or before March 6th.

MANSFIELD UNION—Medical Officer for the First District, and the Work house. Salary, £50 and £40 per annum, respectively.

MILFORD UNION, co. Donegal—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.

MORVEN, Parish of, Argyshire—Medical Officer. Salary, £100 per annum. Applications to H. A. Fraser, Morven, N.B.

NAAS UNION—Medical Officer for the Clane and Tunahoe North Dispensary District. Salary, £125 per annum, and £15 as Sanitary Officer. Applications to be made on or before the 27th instant.

NEWMARKET UNION—Medical Officer and Public Vaccinator for the Third District. Salary, £45 per annum, and fees. Applications to be made on or before March 8th.

QUEEN'S HOSPITAL, Birmingham—House-Surgeon. Salary, £50 per annum, with board, lodging, and washing. Applications to be sent in on before March 11th.

REDDITCH and DISTRICT MEDICAL ASSOCIATION—Medical Officer. Salary, £150 per annum, with fees and unfurnished house.

ROYAL EDINBURGH ASYLUM—Assistant-Physician.

ROYAL INFIRMARY FOR WOMEN and CHILDREN, Waterloo Bridge Road—Physician.

SAFFRON WALDEN UNION—Medical Officer for the Seventh District. Salary, £86 per annum.

SHEFFIELD PUBLIC HOSPITAL and DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.

SOUTHPORT INFIRMARY—Resident House-Surgeon. Salary, £100. Applications to be made on or before March 1st.

ST. BARTHOLOMEW'S HOSPITAL—Two Casualty Physicians. Applications to be made on or before March 3rd.

ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.

ST. THOMAS'S HOSPITAL—Assistant Obstetric Physician.

SOUTH ESSEX DISPENSARY—Surgeon.

TORBAY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.

ULVERSTONE UNION—Medical Officer for the Hawkshead District. Salary, £20 per annum.

UNIVERSITY COLLEGE, London—Curator of the Museums of Anatomy and Comparative Anatomy. Salary, £200 per annum. Applications to be sent in on or before March 6th.

WORCESTER DISPENSARY and PROVIDENT MEDICAL INSTITUTION—Dispenser. Salary, £70, with furnished apartments, coals, and gas. Applications to be made on or before March 1st.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

***BRUNTON**, John, M.A., M.D., appointed Surgeon to the Artists' Amicable Fund, vice J. Templeton Kirkwood, L.F.P.S., deceased.

DRAFER, W., M.R.C.S. Eng., appointed Surgeon to the York Dispensary, vice W. Procter, M.D., resigned.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

DEATH.

BROWN—On October 19th, 1874, of acute laryngitis, at Inverell, New South Wales, Francis Marshall, fourth son of the late Baker Brown, F.R.C.S., aged 30.

BEQUESTS.—The late Mr. Roger Lyon Jones, amongst many other benevolent institutions, has bequeathed the following sums to the medical charities of Liverpool and the neighbourhood—viz., to the Liverpool Medical School, to found a scholarship, £2000; to the Liverpool Bluecoat Hospital; to the Royal Infirmary, Liverpool; to the Royal Southern Hospital, Liverpool, £1000 each; the Northern Hospital, Liverpool, £500; the Children's Infirmary, Myrtle-street, Liverpool; the School for the Deaf and Dumb, £250 each; to the Eye and Ear Infirmary, £200; to the Liverpool Hospital for Cancer and Skin Diseases, and the Liverpool General Hospital for Consumption and Diseases of the Chest, £100 each, all free of duty. In addition, the large residue of the personal estate is to remain on trust for all or any of the charitable and religious institutions mentioned in his will, or such other religious and charitable institutions in Liverpool and the neighbourhood, and in such a manner as the executors think fit.—Miss Harriette Mary Derwick has bequeathed £700 towards the funds of the Convalescent Home, Stillorgan; £600 to the Hospital for Incurables; and £200 to St. Vincent's Hospital, Dublin.

LONGEVITY.—The obituary of the *Times* of the 23rd instant, contained amongst others, the deaths of no less than twenty-three persons, whose united ages amounted to 1,864 years, giving an average of more than 81 years of age to each. The oldest, a lady as usual, had reached the great age of 99 years, the youngest being 71.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 7 P.M. Ballot for the election of Officers and Council; to close at 8. 8 P.M. Dr. Farquharson, "A Case of unusually rapid Action of the Heart"; Dr. Carpenter (of Croydon), "On the Rational Treatment of some Forms of Hemiplegia";—Odontological Society, Dr. Barthurst Woodman, "On the Colouring Material of the Pink and Red Vulcanite or Rubber manufactured for the use of Dentists, and on some Cases of Chronic Poisoning apparently due to this Pigment".

TUESDAY.—Pathological Society of London, 8.30 P.M. Mr. Hutchinson: Drawings and Casts illustrating the kind of Teeth usually met with in Zonular Cataract. Dr. Barlow: Aneurism of the Heart. Mr. Hulke: Specimens of Epithelioma. Mr. Howard Marsh: Malignant Disease of Testis. Dr. Douglas Powell: Aneurism of Aorta. Mr. Barwell: Myeloid Sarcoma of Humerus. Mr. Godlee: Blood-Cyst in Sarcoma. Mr. John Wood: Tumour of Scapula. Mr. Knowles Thornton: Ovarian Cyst with Papillomatous Growth. Dr. Julius Pollock: Worms in Head of Dog. Dr. Crisp: Tubercle in Pheasants. Dr. Crisp: Cancer in Common Fowl.

WEDNESDAY.—Obstetrical Society of London, 8 P.M. Dr. Oswald, "Notes of a Case of Suppurating Tumour of the Left Ovary, with Specimen"; Dr. Liebman (of Trieste): "Clinical Notes on the Early Course of Cancer of the Cervix Uteri"; Dr. Savory, "Case of Epithelioma of the Cervix Uteri complicated with Pregnancy; Removal of Diseased Portion; Subsequent Delivery of a Healthy Child; Recurring Pregnancy"; Dr. George Roper, "On Prolapse of the Funis during Labour"; and other communications.—Royal Microscopical Society, 8 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the *JOURNAL*, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

IGNORANT.—1. Billroth's Pathology: H. K. Lewis, 136, Gower Street, W.C. 18s. 2s. Maunier's Operative Surgery, second edition: J. and A. Churchill, New Burlington Street. 6s.

MEDICAL ETIQUETTE.

HONESTAS.—As far as can be judged from the statement before us, the conduct of the practitioner referred to has been far from courteous. But, as we know nothing of any extenuating circumstances which he may have to urge in defence, it is scarcely possible to pronounce a decided opinion on the matter.

PROVIDENT MEDICAL CLUBS.

SIR.—I should be glad if some of my medical brethren would kindly let me have a scale of annual payments to ensure medical attendance in illness for the wives and children of labouring men, mechanics, and small tradesmen, in an agricultural district, with rules of such a club, and any hints as to the mode of working it.

It appears very desirable to save such people from hopeless, sometimes ruinous, accumulation of debt in illness, for their own sakes as well as for that of their doctors.

Yours very truly,

J. LEE JARDINE.

Capel, Surrey, 24th February, 1875.

W.M.—A C.M. of the University of Edinburgh is entitled to call himself "Surgeon" on his doorplate and elsewhere.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

NOTE ON FUNGUS MEATUS AUDITORI EXTERNI (ASPERGILLUS).

D. McD. has replied to my request of the 6th inst. The three specimens which he sends are beautiful examples of *aspergillus niger*. This proves that the ear disease he suffered from was fungous in its character.

Dr. Macnamara, of Bruff, county Limerick, likewise forwarded a specimen of supposed fungus. This, on examination, proved to be not a fungus, but a portion of a steatomatous tumour.

Max Jacobin is permitted to ask my professional brethren to forward specimens as requested in my communication of the date above mentioned.

JAMES PATTERSON CASSELLS.

2, Newton Terrace, Glasgow, Feb. 25th, 1875.

WILL DR. BOND kindly submit his paper on Disinfectants by giving the formulae for cupralum and ferralum? H. F. SMITH.

MEDICAL DEGREES AND TITLES.

SIR.—In a letter on Medical Degrees and Titles in last Saturday's JOURNAL, signed "A Country Practitioner," I read the following: "He must remember that the standard required for University honours differs at each of the Universities of the United Kingdom, and it would seem, therefore, as sensible to deny a B.A. of Aberdeen the right of using the title because he did not obtain it after the same ordeal as at Oxford." "A Country Practitioner" will oblige by answering the following questions in next week's BRITISH MEDICAL JOURNAL. 1. What is the ordeal at Oxford, and what is the ordeal at Aberdeen, for obtaining the degree of B.A.? Explain and compare the two. 2. State and compare the course of study, the standard of examination, and the number of years required to obtain a degree both in Arts and in Medicine at the several Universities of the United Kingdom.

Accept my apology for this note, and believe me, yours truly,

February 6th, 1875.

DUM SPIRO SPERO.

SIR.—If your readers are not quite tired of this discussion, will you allow me to prolong it with a practical suggestion? Your correspondents have alluded to some degrees as higher than others. In the present state of confusion it is difficult to say what degree or license ranks the highest. In general society, whatever costs most money is most highly esteemed; and therefore, an Oxford or Cambridge degree, representing an outlay of a couple of thousand pounds, is estimated more highly than a London license or Scotch degree costing a quarter of that sum, and nothing that the profession can do will alter this general opinion. What degree stands highest in professional estimation is very doubtful. Every man swears by his own place of education, and patients in general consider their own medical attendant the perfection of wisdom and attainments. That certain degrees and diplomas differ in the kind of knowledge they represent is true enough; but that one is always superior to another, except in expense, is very questionable.

As regards the title of Dr., an M.D. is no more a physician than an LL.D. is a barrister or an M.A. a clergyman. A degree is merely a certificate of competency more or less according to its origin; but a license to practise is, or at any rate used to be, given by totally different bodies in each of the three professions. If the L.R.C.P. is not a Doctor, neither is the M.D. a physician, any more than he is barrister or a clergyman. If the L.R.C.P. covet the title of M.D., so may the M.D.s that of L.R.C.P.; and if one would have taken the degree, if when young he had been aware of its value, so would the other the Fellowship, if his friends would have paid the fees.

To a very young man beginning practice a good degree is certainly of value, but after a few years every man establishes a position independent of academical distinctions. Indeed, since examinations of all kinds have become so common, the persons one meets in society consider them but different tests of knowledge. In Universities, students, if moderately diligent, are sure to pass at the conclusion of their residence, because the examiners are the teachers, and a student knows exactly what is required of him. In the case of the mere examining boards, the result is very different; the hardest working men, even with the best abilities, are not the most successful; but those come out the best who have been most fortunate in their grinders.

But, practically, can anything be done for the L.R.C.P.s who covet the title of M.D.? An Oxford man objects to his University granting them honorary degrees; and it would be unfair to place pressure on the Scotch Universities to satisfy Englishmen. They were established for the benefit of Scotchmen, who are perfectly satisfied with their rules. The peculiarity of the Scotch Universities is the goodness of their professorial. Notwithstanding their poverty and want of endowment, they have always paid their professors so well as to draw away the best men from England. The Universities of Scotland have always on this account been considered good places for study, whatever value may have been attached to their degrees. Indeed, residence and diligent attendance at lectures have been more insisted on than cleverness in answering at an examination. It would obviously be unfair to the existing graduates to give degrees from such Universities without the statutory residence. But the University of London was founded for the benefit of the residents in that town; and as that corporation is merely an examining body, it would be perfectly fair to bring parliamentary pressure to bear upon it, to compel it to perform the duties for which it was established. Those who wish for a degree "after a good practical examination" should apply to the University of London, and, on refusal, petition Parliament. If, however, the graduates of London should object to their degrees being conferred after a "good practical examination", there yet remains a method of obtaining the coveted letters without lowering the degree. The only difficulty in graduating in London is in passing the matriculation. When that ass's bridge is passed, the remainder of the course is sufficiently easy. The real difficulty of this examination arises from the uncertainty of the subjects required; and certain obvious reforms would render it as easy as the matriculation of any other University or examining body.

First, the examinations might take place four times in the year, so that a man ploughed at one should not lose half a year's, or more, residence at a medical school. Second, a man passing the greater number of the subjects, should be allowed to begin his proper medical course on condition of passing the remainder of the subjects at the next examination. Third, the examination should be made more public. Every candidate should give in the names of his tutors during the last twelve months there; the examination papers should be filed, and these tutors allowed to look over all the papers—those of the successful as well as of the unsuccessful candidates. Fourth, the names of the examiners and of the assistant-

examiners should be published, or at least hung up in the examination-hall. Fifth, no private tutors should be examiners, either for their own pupils or for those of others.

Those who know anything of corporate bodies will be aware of the strenuous opposition that each of these regulations would call forth; but the University of London, being under the authority of Government, it would be comparatively easy to bring pressure to bear upon it. The British Medical Association, if united upon this subject, might effect some such reforms in a very short time.—I am, sir, your obedient servant,

M.D. EDIN., M.A. DUBLIN.

P.S.—Medical men are either so busy that a degree more or less would be of no consequence, or are only partly occupied, when the getting up of their old subjects of study would be a good discipline; and any one who has tried will be aware how easily this may be done.

PRELIMINARY EXAMINATION FOR THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS.

MY son has passed the preliminary examination for membership, and wishes to present himself for the fellowship, next June. Will some of your readers kindly say, if he presents himself for Chemistry, in addition to the Greek, and passes, will he be entitled to the Certificate of Fellowship so far as the Preliminary is concerned? The official circular is somewhat vague upon the point as far as regards optional subjects.

I should also be glad to know if I can obtain some of the "back papers" of the examination, so that my son may have an idea of what the Chemistry embraces, and what is the character of the Greek examination. INQUIRER.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Gazette; The Midland Counties Express; The Hull and Eastern Counties Herald; The South Eastern Gazette; The Alderston Chronicle; The Auckland Times and Herald; The Western Daily Press; The Manchester Guardian; The Ulster Advertiser; The Sussex Coast Mercury; The Broad Arrow; The Surrey Advertiser; The Pedale and Northallerton Times; The Hackney Express; The Liverpool Porcupine; The Scotsman; The Liverpool Mercury; The Glasgow Herald; The Stroud News and Gloucestershire Advertiser; The Bradford Observer; The Morpeth Herald; The Portsmouth Times; The Western Daily Press; The York Herald; The Sheffield Evening Star; The Brighton Guardian; The Sussex Daily News; The Wrexham Advertiser; The Newton Directory; The Sussex Coast News; The Berkshire Chronicle; The Hull News; The Southern Times; The Worthing Intelligence; The Hampshire Telegraph and Sussex Chronicle; The Sheffield Daily Telegraph; The Hereford Times; The High Peak News; The Brighton Daily News; The Bath Argus; The Pembrokehire Herald; The West Briton and Cornwall Advertiser; The Glasgow Herald; The British Mail; The Indian Medical Gazette; The West Country Lantern; the Ripon Gazette; The Airdrie Advertiser; The Manchester Courier; The Wolverhampton Chronicle; The Cork Constitution; The Sheffield and Rotherham Independent; The Liverpool Daily Post; The Redruth Times; The Hackney Express; The Hour; The Paddington Times; The Newton Directory; The Wolverhampton Chronicle; etc.

COMMUNICATIONS LETTERS, ETC. have been received from:—

THE CROONIAN LECTURES ON DISEASE OF THE SUPRARENAL CAPSULES.

Delivered at the Royal College of Physicians, London.

By E. HEADLAM GREENHOW, M.D., F.R.C.P., F.R.S.
Physician to and Lecturer on Medicine at the Middlesex Hospital.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—Upon my appointment to the honourable position of Croonian lecturer of the present year, I selected for my subject Addison's disease. The first, and perhaps the chief, reason which induced me to make this selection was, that the study of this disease has always been to me a matter of special interest, and has engaged my attention at every available opportunity ever since the announcement of its discovery. But another reason which also weighed with me in making a choice of my subject was, that the discovery, which must be accounted among the great medical discoveries of the present century, and which may with propriety rank side by side with Dr. Bright's discovery of the relation between dropsy and disease of the kidneys, has never to this time been made the subject of any of the lectures delivered before this College, of which the discoverer was an eminent Fellow. And now, sir, before I address myself to my proper subject of Addison's disease, permit me to say a few words respecting Dr. Addison himself. For it seems to me that to show—though of necessity but briefly—from what and how Thomas Addison rose to become one of the most eminent physicians and ablest clinical teachers of the day, is on the present occasion only a fitting tribute to his memory.

Dr. Addison belonged to that class of men, numerous in this country, who, by their abilities and energy, have raised themselves from the lower ranks of society to the most exalted position in their respective callings. He was born in the year 1795 at Long Benton, a small village in Northumberland, three miles and a half from Newcastle-upon-Tyne. His father was a grocer and flour-dealer. Though of humble station, he must have been a man of enlarged views, for he not only gave his son the best elementary education within his reach, but he aspired to start him in life on a higher social level than his own. Dr. Addison himself told me that his father designed him for the law; but personal predilections induced him to embrace the profession of medicine. He was first sent with his brother to a school kept at a roadside cottage by one John Rutter, a parish clerk, from whom, some years later, Robert, the son of George Stephenson, received elementary education in the same house, whilst his father was engaged as an engine-worker at the neighbouring Keworth collieries. He was subsequently removed to a school of the higher class, and thence he went to Edinburgh, and became a medical student. Fortunately, his father had both the means and the desire to afford his son every possible advantage for acquiring a knowledge of his profession. The opening out of collieries in the parish had largely increased his custom among the good folks in the neighbourhood, and he had become rich for his station. Addison, therefore, after passing through the necessary curriculum of medical study, took the degree of M.D., and was enabled to come to London, where he first became House-Surgeon to the Lock Hospital, and subsequently Physician to the Carey Street Dispensary, and also, I think, to the Royal Infirmary for Women and Children in the Waterloo Road. Soon after his arrival in London, he entered as a pupil at Guy's Hospital, and, in a comparatively short time, he was raised to be a member of the medical staff. In this position, he speedily made for himself a great reputation as a practical physician and clinical teacher. A wide experience acquired in such various fields of study, together with his own great natural powers of insight, sufficiently explain the apparently intuitive knowledge of disease, and the almost unrivalled powers of diagnosis, which formed the basis of his great and real success in professional life. For his success was real; it was not small, if estimated in the lower sense by pecuniary results; but, if estimated in the far higher sense by his achievements and reputation, his success was great indeed, and such as only a favoured few can hope to equal. In some subjects, he was far in advance of his day. Pathological truths which

he enunciated thirty years ago, with respect to diseases of the lungs, have only recently won their way to general acceptance. The discovery with which his name will ever be associated was published to the medical world nearly twenty years ago, and has not yet been generally accepted, nor even generally understood. Dr. Addison died at Brighton in June 1860, and was interred in Cumberland, from which county his family had sprung, and where his maternal grandfather had been a respectable yeoman. I trust that this slight sketch of one of the most eminent members of this body will not be deemed an unsuitable prelude to lectures devoted to the elucidation of his most famous work.

Dr. Addison had been nearly thirty years on the medical staff of Guy's Hospital when he discovered the disease to which you, sir, if I mistake not, were the first to apply the name of Addison's disease. To quote his own words, he had for a long period observed a form of general anaemia occurring without discoverable cause in cases in which there had been no previous loss of blood, no exhausting diarrhoea, no chlorosis, no purpura, no renal glandular tumours or malignant disease, and which he, therefore, designated idiopathic anaemia; a disease which presented in every instance the same general character, pursued a similar course, and, with scarcely a single exception, was followed at a variable period by the same fatal result. He further stated that the leading characteristic features of the state to which he directed attention were anaemia, general languor and debility, remarkable feebleness of the heart's action, irritability of stomach, and a peculiar change of colour in the skin, occurring in connection with a diseased condition of the suprarenal capsules. The characteristic discoloration, he said, pervade the whole surface of the body, but commonly most strongly manifested on the face, neck, superior extremities, penis, scrotum, flexures of the axilla, and round the navel. It presented a dingy smoky appearance of various shades, deep amber or chestnut-brown; and in one instance the skin was so universally and deeply darkened, that the features of the patient might be taken for those of a mulatto. This discoloration was never attended by any harsh dry condition of the surface. To complete the picture, he added that there were occasional actual vomitings, palpitation and breathlessness on exertion, indications of a disturbed cerebral circulation, a strongly marked tendency to the formation of fat, in striking contrast to the failure and exhaustion observable in every other respect. He had, therefore, before his eye a distinct definite morbid state, the nature and cause of which he sought to discover; and his discovery, when made at length, was no chance hit, but the result of long and careful investigation. Accurate clinical observation had first led him to discriminate in the living patient a remarkable train of obscure and apparently causeless symptoms, always of fatal augury; and, while searching out the hidden pathological cause, it was only after the careful exclusion of all other morbid conditions that he referred them to a disease which he found seated in the suprarenal capsules.

It is necessary to dwell upon this point, because at a subsequent period, when he came to publish his monograph, Dr. Addison deviated from his own accurate conception, and subjoined to his own cases several others which he had not seen during life, which, so far as could be known, had presented no constitutional symptoms that could not be accounted for by malignant or other obvious disease, and in which there was only very partial discoloration of skin, or discoloration not at all corresponding with the graphic description I have quoted from his pages. These mistakes of Dr. Addison's were the more remarkable, because, in the first place, as we have seen, he himself states that the chief motive of his investigation had been to determine the cause of symptoms which could not be accounted for by any discoverable disease; and, in the second place, his great knowledge of skin-affections must have made him familiar with the fact that various organic and cutaneous diseases are attended by more or less pigmentation of the skin, though none of them by a pigmentation presenting all the peculiar characters of the discoloration which he had described. These mistakes were doubtless due to the enthusiasm of mind attendant on his discovery, which led him to endeavour to include as much as possible within its scope; but, unfortunately, their effect has been to confuse his own true clinical and pathological description, and to give rise to misconceptions which are still far from being eradicated. We have Dr. Wilks's authority for the fact that, at a later period, Dr. Addison's views were more in accordance with present knowledge; but unfortunately he died, and did not revise his monograph.

As with respect to most other discoveries, several previous observers had stumbled upon the facts which Dr. Addison had discovered. His eminent colleague Dr. Bright had observed, and recorded in reports of medical cases, a case of Addison's disease. It was in all respects a well marked example, and Dr. Addison included it in his monograph, where it stands as Case 5. Mr. Sibley also in 1854 recorded in the

Med. et Reg. of Middlesex Hospital a case of Dr. Seth Thompson's which presented all the main features of Addison's disease, including the discoloration of the skin. Dr. Kirkes likewise reported a case in St. Bartholomew's Hospital several years before the publication of Dr. Addison's discovery, in which the asthenia, nausea, and vomiting had been observed in life, and in which, after death, the only lesion was the lesion of the suprarenal capsules which I shall hereafter describe. At a more remote period than any of these, a case in the Hull Hospital was recorded, almost typical as regards its clinical history, and also its pathological appearances, and closely resembling the case of a girl who died under my own care in 1865. It is true that in neither of these early cases was any discoloration of the skin noted; but we need not infer that it was necessarily absent, seeing that in my own case the discoloration, though characteristic, was so slight that it might have been easily overlooked, more especially at a time when its importance as an indication of the nature of the disease was totally unknown. In such circumstances, we may be quite sure that the discoloration of the skin in Dr. Bright's and Dr. Thompson's cases must have been well marked, or it would not have held the prominent place it does in the description of the symptoms. I refer to these two last cases with special pleasure, because more striking illustrations can scarcely be used of a truth which I have always felt, and which was so well expressed by Dr. West, the last Harveian orator: that the mere details of which, when we have ascertained them, we cannot see the purport or the uses, will sooner or later surely find their place.

I cannot close these introductory remarks without some reference to two distinguished living members of the profession, but for whose labours Dr. Addison's discovery might possibly have attracted at the time but little attention. Soon after the publication of the monograph, Mr. Jonathan Hutchinson gave a wide-spread impulse to the discussion of the subject, by collecting and publishing all the cases he could obtain, bearing upon the question of the reality of the disease and its relation to a morbid process in the suprarenal capsules. To Dr. Wilks, we are even more deeply indebted for much of the advance towards our present knowledge of the disease. In a succession of papers published in the *Guy's Hospital Reports*, he described all the chief symptoms of the disease, and more especially the pathological appearances in the suprarenal capsules, in a large number of cases which had either occurred in the practice of the hospital, or had been submitted to him by other medical men for examination; and he further brought forward the truth obscured by the admission of spurious cases in Dr. Addison's monograph, that all genuine cases of the disease are due to one and the same characteristic lesion of the suprarenal capsules.

Notwithstanding the misconceptions which have prevented the general recognition of Dr. Addison's discovery, we have made, as I have said, much advance in the knowledge of the disease since Dr. Addison's time. More than three hundred cases have now been recorded, some in almost every country in which medical science is cultivated. Of these, many are so imperfectly reported that no conclusions can be fairly drawn from them as to the existence of the disease, and others again, which present neither the clinical nor the pathological conditions described by Dr. Addison, are obviously not cases of Addison's disease at all, although published as such. But, on the other hand, by far the larger number are true cases of the disease, having presented, in a more or less developed form, its characteristic clinical phenomena, together with the particular lesion in the suprarenal capsules; while a considerable number are what I may term typical cases, *i.e.*, cases in which no pathological lesion of any importance was found, except the one particular lesion in the suprarenal capsules. Eight of these typical cases have come under my own care or observation, several of them in the Middlesex Hospital; and I pass now to the delineation of the living picture of Addison's disease, as it has repeatedly presented itself to me in these and other cases, unmistakable at first sight to one who held the key of the mystery supplied to Dr. Addison's discovery. There are progressive asthenia, having often originated without any apparent cause, seldom dating from any definite period; an insupportable aspect of listlessness or depression; great languor and indisposition for exertion; almost invariably a remarkable weakness of the heart's action; a small, feeble, compressible pulse; loss of appetite; irritability of the stomach; nausea and retching. There are usually more or less severe and frequent pains in the loins and epigastrium, and not uncommonly tenderness on pressure in one or both hypochondria; a rigidity of the abdominal muscles, as if instinctively contracted to protect deep-seated parts from pressure. In advanced cases, vomiting is seldom absent, and it is sometimes spontaneous and irrepressible. There are usually breathlessness, palpitation on making any muscular effort, frequent sighing or yawning, and sometimes a persistent hicough; generally, faintness or giddiness on rising, or even on being raised up in bed. Notwithstanding, however, the great feeble-

ness, which is one of the invariable symptoms of the disease, there is, in uncomplicated cases, comparatively little or no real emaciation; but, on the contrary, together with some appearance of partial wasting, there is always a fair amount, and often a considerable excess, of subcutaneous fat, and the skin remains soft and smooth. The temperature, as a rule, is below the normal. The skin and extremities are cool, if not cold, to the touch. The urine is often small in quantity, and generally of low specific gravity, and deficient in solid constituents. The bowels are mostly confined, the tongue usually ruddy and moist until the advent of typhoid symptoms during the last days of life. The mind is often clear to the last; but so great is the prostration in the later stage of the disease, that the patient lies in a drowsy and semicomatose state, from which he can only be roused by questions addressed to him, and he then gives pertinent, though slow and monosyllabic, answers. In this stage of the disease, the temperature falls considerably below the normal, and death takes place by asthenia, and sometimes at the last almost suddenly, apparently in syncope. There is, on the other hand, in many cases towards the close of life, incoherence or delirium, sometimes low muttering, sometimes more loud and active, and in these cases death often takes place in coma. In one of my own most typical cases, the patient had a convulsive fit, and lay for hours before death with firmly closed jaws and great rigidity of the muscles of the abdomen and extremities. He was seemingly unconscious, but whenever he was touched convulsive twitchings took place, either of the face or of the whole body. Various other symptoms equally referable to the disturbance of the nervous system, such as vertigo, numbness or anaesthesia of the face and arms, and more rarely of the lower extremities, dimness of sight, flashes of light before the eyes, noise in the ears, deafness, tremors, rigors, and even epileptiform and other seizures, have been recorded in many cases as occurring in the course of the disease, and in a few as having been the principal symptoms observed during life, except the invariable languor and general debility.

To this sketch of the characteristic constitutional symptoms of Addison's disease, I must add the description of the peculiar change of colour in the skin as it has struck my own eye in every advanced case. This consists, as is generally known, in a gradual darkening of the skin on various parts of the body, or even the whole body. The aspect of this discoloration, when fully developed, is very remarkable, and gives the patient the appearance of belonging to one of the dark races of mankind. Most frequently it has a dusky, smoky, or yellowish brown hue; sometimes it is of a green brown colour, and when deepest approaches in parts the tint of negro skin. The discoloration is never uniform over all parts of the body. It commences paler, and becomes deeper on all or some of the exposed parts, the face, neck, dorsum of the hands and fingers, and all those parts which are naturally the seat of pigment on the general surface. Sometimes there is universal discoloration, but more frequently it is only distinctly obvious on certain parts of the body. Even in the latter case, however, it probably affects in some degree the whole cutaneous surface; for, on a microscopical examination of parts of the skin, which, by contrast with the darker parts, appeared normal, I have found in them small quantities of the pigment which imparts an abnormal colour to the skin. The transitions from the dark to the paler shades of discoloration on different parts of the body are never abrupt. The darker parts are never in defined patches, but merge into the other and lighter parts of the surface. There is, however, one marked exception to this. When the skin has suffered any superficial abrasion or injury, or when the patient has been blistered at a recent period, the injured parts not only become much darker than the surrounding portions of the surface, but present defined margins, coinciding with the extent of the cutaneous injury. In the case of two patients of my own, I found abrupt dark defined patches on the epigastrium, and I ascertained that they were the seats of blisters which had been applied a short time before. In the case of the second patient, who survived nearly two years, the dark patch gradually faded away, and before death ceased to be visible. In the other patient, the deep cicatrices caused by cupping more than twenty years before remained perfectly white. Each little scar was surrounded by a distinct border of dusky discoloration. It does not require, however, actual abrasion of the skin to excite a greater deposit of pigment in certain parts. Slight local irritation of the surface appears in a few cases to have produced the same effect. I have seen dark streaks on the skin corresponding with the lines of pressure exerted on particular parts by petticoat strings and garters, and the same circumstance has been noticed by others. In a case recorded by Dr. Nicholson in 1873, it is stated that the patient, a baker's lad, presented on his shoulders dark stripes corresponding to the bands by which the basket he carried was slung at his back. I was anxious to show some drawings illustrative of this remarkable discoloration of the skin, but it is most difficult to procure good drawings of it. The fact is, that the discoloration is so like the colour of a dark

person, that it is almost impossible to get a thoroughly good illustration. I have had, therefore, to fall back upon the two lithographs before you, one of a patient of Dr. Hughes of Dublin, and the other of a patient in Guy's Hospital. The dark picture represents a colour much darker than any that I have seen, but I was assured that it is not darker than the patient really was during life.

The discoloration of Addison's disease is not entirely restricted to the skin; it is also frequently observed upon the mucous membranes of the cheeks and gums, also upon the tongue, and on the lips, where it takes the form of an irregular bluish-black streak, running longways near the junction of the mucous membrane with the outer skin. It is seen on the gums and buccal mucous membrane in the form of irregular stains and patches, mostly brownish, with an ill-defined border. In two of my own cases, the stains on the buccal mucous membrane have corresponded with seats of irritation produced by the pressure of protruding teeth; but, in other cases, I have been unable to verify any such cause. These stains on the gums and buccal mucous membrane form another point of analogy between the discoloration in Addison's disease and the pigmentation natural to the dark races of men; for several Lascars who have come under my own care in hospital have presented on the same parts stains similar to those that I have described. The discoloration of the tongue appears usually in the form of sharply defined stains of a purplish blue, or somewhat inky hue. In my own cases, these stains have always been situated near the free margin of the organ. The conjunctivæ always remain normal, and the contrast between their pearly whiteness and the dusky hue of the discoloured skin is striking, and involuntarily recalls the similar contrast in the mulatto or negro countenance.

We see, therefore, that the discoloration of the skin in Addison's disease usually begins and eventually becomes deepest on those parts which are naturally most liable to become pigmented, either by exposure to the sun and air, or by the excitement of certain physiological processes. To these may be added such parts as may accidentally be subjected to the excitement of local irritation. In other words, this peculiar change of colour is, like many other pathological processes, merely an exaggerated, and therefore a morbid, development of a natural physiological process. On a microscopical examination of sections of discoloured skin, the discoloration has seemed to be due to a deposit of yellowish brown pigment in the deeper layers of the epidermis, more especially in the layer in immediate contact with the papillæ, while the more superficial layers of the outer skin mostly remain free from pigment. Here is a drawing, highly magnified, of a portion of the skin, showing the hair and some deposit in the papillæ; and there is also another drawing of the skin of a negro, which will show that the discoloration in Addison's disease is in the same part as the discoloration seen in the negro and Lascar. The deposit is generally seated in the layer immediately in contact with the papillæ; nevertheless, I have found in several cases traces of pigment in some of the more superficial scales of the epidermis, and also pigment-granules deposited here and there in the cutis. There is a specimen here under the microscope which shows very well the ordinary arrangement of the discoloration over the papillæ, and also shows some of these pigment-granules in the true skin: they are not usually found in that situation, but fortunately I have one specimen which shows that they are sometimes found more deeply seated than is usual. Dr. Sidney Coupland also microscopically observed pigment-granules, both isolated and in groups, in the connective tissue of the cutis at some distance below the epidermic layer. The principal part of the pigment, however, is in every case deposited in the cells of the rete Malpighii; it is accumulated round nuclei, but some of it is generally free and irregularly distributed; this latter portion of pigment has also been originally contained in cells, which have disintegrated and allowed the colouring matter to escape. A physician at Halle, in the case of two patients, on a sectional examination, found many pigmented connective tissue-cells in the papillary portions of the cutis; and Mr. Schäfer observed in the same portion of skin a number of irregularly shaped corpuscles containing a considerable amount of pigment. The colouring matter in the patches on the tongue is deposited in a corresponding situation with the stain on the skin, being seated in the lower cells immediately overlying the papillæ; the superficial layer of epithelium remaining quite free from pigment.

To those who have carefully examined the skin of negroes and Lascars, or persons belonging to other dark races of men, it would be obvious, from this description, that the differences between their normal colour and the abnormal pigmentation of Addison's disease are merely differences of degree; although in the former physiological conditions, and in the latter pathological causes, have operated to produce them.

(To be continued.)

CASE OF ACUTE OTITIS MEDIA: SUPPURATIVE INFLAMMATION OF THE MASTOID REGION: DEATH.

By F. M. PIERCE, M.D., L.R.C.P. Lond.,
Honorary Medical Officer, Manchester Ear Institution.

THE following case presents some features of especial interest to anatomical surgeons, though not partaking of a very uncommon character. I regret that I had not the opportunity of making more detailed observations of this case; it was seen by me once only, and the rapid termination did not allow a second examination.

C. M. L., aged 16, mechanic, was admitted to the Hulme Dispensary on January 16th, 1875, under my colleague Dr. Railton, one of the surgeons to the charity. He had always enjoyed good health, and seemed a well made youth. He never had any fall or blow upon the head. One month before admission, he noticed slight deafness and pain in the right ear. About a fortnight later, the mastoid process became swollen and tender. A week before admission, after severe pain in the ear and about the temple, a purulent discharge came from the right auditory meatus. On admission, Dr. Railton, knowing my interest in aural diseases, requested me to see the patient with him. I found the boy complaining of severe pain in the depth of the ear, about the mastoid, and down the neck. There was a profuse purulent discharge from the right ear; the mastoid region was greatly swollen, red, and soft, and causing great projection of the auricle. The hearing distance for a watch was 48 c. No tuning-fork was at hand to test by that means. There was no paralysis or affection of any of the cranial nerves. A lotion of sulphate of zinc, with carbolic acid, was ordered to be instilled warm into the ear every two or three hours, and the entire part bathed with it. An incision was made into the mastoid swelling half an inch from, and parallel to, the auricle, without liberating any pus, and followed by linseed poultices, etc. When seen by Dr. Railton on the 19th, the patient had slept very little, owing to severe pain at the back of the head, which had been temporarily relieved by the incision, from which there was now considerable discharge of pus. There was no vomiting nor delirium, or any hæmorrhage from the external meatus. On the 21st, the discharge from the mastoid region was very offensive and profuse, that from the auditory meatus much diminished. The patient was very restless, frequently tumbled down, and kept his head clasped between his hands, which he said "relieved the pain at the back of his head and neck". Convulsive movements of his left arm and leg were now very noticeable. The left arm and leg were constantly being jerked about in an involuntary manner. His appetite and vision remained good to the last.

On the 22nd, the symptoms grew worse, though he still ate well, and was quite conscious, answering questions put to him. The convulsive twitching of the left extremities continued, and he sat with his head upon a pillow placed over the back of a high chair. About 8.30 p.m., his face changed colour very frequently: the left ear and side of the head suddenly became of a dark purple hue, his head dropped forward, and, after a few groans, he died. On carefully questioning his mother, she was certain that there was no squinting or facial paralysis; that "she was sure there was nothing the matter with his face at any time during his illness". No signs of cerebral irritation were present when he attended at the dispensary. Unfortunately, permission to make a *post mortem* examination could not be obtained.

REMARKS.—The above account gives all the facts of the case; but, in the absence of any pathological examination, some caution is necessary in accounting for the exact mode in which death ensued in this patient. This fatal attack of mastoiditis was unlike most cases, in being the result of an acute aural catarrh, and not of a chronic otorrhœa. Toynbee speaks of having seen but one case of abscess of the brain due to acute ear-disease. There was no history of any throat-affection, but it is probable that such existed to a slight extent at first. Want of opportunity did not enable me in this case to discriminate between mastoid periostitis and caries at the outset: a distinction often difficult to determine. The discharge from the right meatus did not suddenly cease, as it usually does, on the development of cerebral complications. If death arose from ulceration into the lateral sinus or carotid canal, there would probably have been hæmorrhage from the nose, mouth, and ear. Abscess of the cerebrium is scarcely probable in the absence of coma, vomiting, and delirium. May we not conclude that examination after death in this patient would have disclosed partial meningitis, with abscess in the right cerebellar lobe and purulent effusion about the medulla oblongata?

THE GOULSTONIAN LECTURES ON PUERPERAL FEVER.

Delivered at the Royal College of Physicians, London.

By ROBERT J. LEE, M.D., F.R.C.P.

Assistant Physician at the Hospital for Sick Children, Great Ormond Street.

LECTURE II.

ONE fact, as Cullen's remarks have suggested, had gradually become evident in his day to those who were interested in the question of the cause of the disease; it was the great mortality that characterised its occurrence in public institutions and hospitals. Long before 1788, when Tenon gave a report of the serious condition of the wards in the Hôtel Dieu, several epidemics, as they were termed, had been heard of. For more than a century before Cullen's *Prætie* was published—that is, between 1652 and 1783—we have notices of this kind. Every author referred to them more or less directly when writing on the subject in the latter part of last century. One of the most distinguished observers of the disease almost commenced his treatise with the words: "The mortality attending the puerperal fever is truly lamentable. In the year 1750, at Paris, none who were seized with it recovered. In one hospital in London, in the space of two months, thirty-two patients were affected with that disease, and all except one fell victims to it." (Gordon's treatise on the *Puerperal Fever*.)

This fact did not, however, appear in the same light to all. We have, among many other examples, that of an excellent physician, Dr. Halme, whose work I have already mentioned, who makes the following benevolent remarks in the dedication of his treatise on puerperal fever to the Governors of the City of London Lying-in Hospital:—"Public hospitals", he says, "for the reception of the sick and hurt are the grand seminaries of practical knowledge in the art of medicine. The utility of these institutions is so apparent, that they are now universally received all over Europe. Great Britain in particular hath not been behindhand in promoting such humane designs. Buildings of this kind, or which incidentally promote the same end, are to be seen in almost every part of this great metropolis. Among the rest, the City of London Lying-in Hospital rises up a simple, yet elegant monument of her beneficence." There is a footnote, to the effect that "this hospital is entirely supported by a voluntary annual subscription, whereby four or five hundred poor objects are admitted every year, and relieved with all necessities during childbirth".

As Halme was an authority on puerperal diseases, we may briefly notice that "the immediate cause" of the fever, in his opinion, was an inflammation of the intestines and omentum, and the "chief predisposing cause the pressure of the gravid uterus against the intestines and omentum". On similar principles of what we should hardly agree to call humanity, but with the additional object of teaching his pupils to "acquire true practical knowledge", Dr. Leake founded a hospital in Westminster, and Dr. Osborn and Dr. William Hunter both enjoyed opportunities of studying the disease in special hospitals.

We may conclude from this that, though Cullen's views were probably generally entertained, yet in the minds of many who were engaged in active professional duties, and who were certainly not deficient in intellect and benevolence, there was no distinct idea that the mortality in lying-in institutions might depend on causes over which there could be exercised very considerable control; so that the question of treatment appeared to be much more important than that of the etiology of the disease. I have mentioned one example of this in the recommendation of doses of ipecacuanha by Dr. Doulet. The report of the French Government on this plan concludes with the observation, that "the cure of a disease so active, and generally fatal in the Hôtel Dieu, and which allows so little time for reflection or hope from medicine, performed by a method so simple as that practised by M. Doulet, the success of which has proved so certain and uniform, is one of those extraordinary phenomena of nature which form an epoch in medicine".

We are not told exactly what other remedies M. Doulet employed; but, from the remark, "that those medicines most frequently administered in putrid diseases approach nearest to the method practised by M. Doulet", it would seem probable that his success may have depended on some other principle than that of promoting the action of the liver

and intestines by emetics, which was one method, in his opinion, by which the effects of a poison might be eliminated.

As it is our object to trace the progress of exact knowledge rather than to review ephemeral views, we may content ourselves with the list of remedies which Dr. Meigs has introduced into his well known work as a quotation from M. Baudeloque, the younger of that name. This is the list:—Blood-letting, emetics, purgatives, sudorifics, antiseptics, tonics, particularly camphor and bark; blisters and other revulsives, cold douches and cold stupes or hot stupes to the belly, subcarbonate of potash, oil of turpentine, mercurials: he ought to have added opium. Such were the differences of opinion on the subject of treatment.

As we have brought our review of the theories and different kinds of practice which prevailed at different periods, from the time of Hippocrates to the latter part of last century, when William Hunter, Cullen, Denman, and many other celebrated men, were contributing in their several departments to the advance of medical science in this country, I shall ask your careful attention to a work which apparently produced no great impression at the time it was published, but which has since had an important influence on our views of the nature of puerperal fever.

This work is by Dr. Alexander Gordon, and contains evidence that the fever depends on a particular poison, which may be communicated by direct contact from one person to another, and that the occurrence of a number of cases of the disease is to be explained in that way rather than by atmospheric or other conditions; that is to say, that the disease does not occur epidemically. It is usual for modern authors to mention the names of Denman in England and Semmelweis in Germany as the chief contributors to this important fact. When I say that these names are associated by modern authors, I mean simply that in our text-books we find some such sentence as the following:—"As a result of clinical observation, on the one hand, the febrile puerperal diseases were proved with certainty to be due to secondary infection first by the English (Denman), afterwards by the Germans (Semmelweis)."

I am now quoting from the German text-book on *Pathology* by Klebs. It may be presumed that the gratifying priority thus accorded to us by German authorities has induced our own writers on the subject to be content with this division and distribution of fame. If it were just, it would be still more gratifying. By way of a little diversion from the direct path of investigation we have been pursuing, I shall ask your attention to this question of priority; not so much because it is of any great importance to determine how or when the fact was first brought to light that puerperal fever depends on a special poison, as to relieve the mind from an uncomfortable feeling that somebody may have suffered neglect. It always appears to me to be better to omit in educational text-books as much as possible all mention of names; but, if they be mentioned, it is necessary that whatever is stated about them should be as certainly true as possible. It is a subject deserving of the consideration of the learned Fellows of this College, why there is such a scarcity of really good works for educational purposes at the present day. It will be answered probably, that science has made such rapid progress as to render it difficult to compose such works as text-books. This is not the case in other sciences; and I have not the slightest doubt that, if there were a general feeling of gratitude to those whose practical knowledge most fits them to undertake such difficult and thought-requiring labour, we should not be long before we could boast of possessing first-rate works of the kind I allude to. But to return to the question of Denman and Semmelweis. Let us take Denman first.

It appears that we have more than one edition of his works, and that considerable periods intervened between their publication. In the last of these, there are the following remarks. "There is another consequence of an epidemic, or even a sporadic puerperal fever, on which it would be criminal to be silent. This is the contagious nature of these fevers, it having been long suspected, and being now fully proved, that they may be, and often have been, conveyed by midwife or nurses from one patient to another. This fact explains the reason why persons practising for many years with the most enviable success have at one or more periods of their lives, without any change in the principles or manner of their practice, met with a number of unfortunate cases when perhaps an adjoining neighbourhood has been entirely free from such diseases," etc. (Denman, p. 644, ed. 1805.)

There is no doubt about the meaning of this passage; and, as it is contained only in the third and last edition, and not a word is said upon the subject of contagion in the former two, we may conclude that our German admirers have quoted from the most recent one. We can easily understand that such a general statement as "having been long suspected, and being now fully proved" is not quite satisfactory to their

love of detail. However, Denman was quite right in saying so; for, in the very year (1795) that he published his second edition, which preceded the third by ten years, the work of Dr. Gordon appeared, and, curiously enough, was dedicated to his intimate friend Dr. Denman. Now, Gordon's treatise contained the results of his observations on an outbreak of the fever in Aberdeen, which continued from 1789 to 1792, and then he allowed between two and three years to elapse before he wrote upon it. It is very probable that he communicated those results to Denman before the year 1795, when, as we have seen, his own work and Denman's second edition were published. If this were true, it would certainly lead us to conclude that Denman was not very willing to believe in Gordon's contagious theory when first proposed to him. If it be asked why did he not refer to Gordon's treatise in his last edition, we can only reply that, as he followed the example of the dogmatic teachers of his day, he omitted on principle the mention of names, restricting himself closely to careful judgment of reported facts, applying to them the test of extensive personal experience. We may also conclude, from the circumstance that Denman was satisfied with the reasons adduced by Gordon for his contagious theory, that, in the interval of nine years between his second and third editions, that theory had been more or less generally accepted.

A very considerable change, in fact, had taken place in the state of knowledge of the nature and cause of puerperal fever. A careful analysis of the kind of evidence brought forward by Gordon to prove his point will show that it was much of the same character as that furnished by Semmelweis. Neither of them used pathology or morbid anatomy to any great extent. The method they both employed was a species of close clinical observation, assisted by correctly logical deduction, and was rather of the nature of proof by circumstantial evidence than of actual demonstration.

It is impossible, however, on comparing the works of Gordon and Semmelweis, to resist the conclusion that, although they were both possessed of powers of original thought and admirable truthfulness and courage, there was a considerable difference in their mental calibre. It requires a full appreciation of that peculiar instinct which is so rarely exhibited, and to which we owe all important advances in scientific knowledge, to estimate the great superiority of Gordon's intellectual and moral character. We can measure various kinds of force, but this mental force has never yet been properly valued. We cannot, of course, but admire the talent and industry which enable one man to work out such a problem as whether or not puerperal fever depends on a contagious poison; but, when the idea is the suggestion of another, we cannot admit that he has any claims at all equal to those which we must accede to the one who first conceived the idea, and who, as far as he was able, applied experimental tests to it.

This was the great difference between the total results of Gordon's observations and those of Semmelweis: the one possessed original powers of perception, which led him to trace such a connection between the various phenomena of the disease as to enable him to deduce a general principle or law by which they were controlled.

Now it is necessary, before we allow to Gordon the merit of this superiority, to examine whether his theory was simply a conjecture, or well supported by observation. I should not have introduced this subject to your notice, if I had not felt pretty well assured that you would agree with me after such an examination. I had another reason, and that was, that I wished to prove a fact of which we ought to feel certain as well as properly proud, and that is, that no country in the world can surpass ours in the production of men of that peculiar genius which in all departments of science characterises their chief pioneers.

Some recent authors have not been so generous to Denman as Klebs. The author of one text-book, which has been translated into English, gives to us the credit of ascertaining the fact, that puerperal fever is contagious or specific; but he claims for Semmelweis the merit of having worked out the subject carefully, and of being essentially the author of all we know of the etiology of the fever (Schroeder). The growing tendency to copy such statements from foreign authorities into our own literature, many will agree with me, is not likely to encourage that kind of work and thought among us upon which the scientific merits of our profession depend.

Let us examine the data on which Gordon established the fact, that, to use his own words, "the cause of this disease was a specific contagion or infection", of which he asserted "he had unquestionable proof". He first undertakes to lay before us evidence that "every person who had been with a patient in the puerperal fever became charged with an air of infection, which was communicated to every pregnant woman who happened to come within its sphere". He submits to us a table of seventy cases, containing the name, age, and residence of each patient, and the name of the midwife or practitioner by

whom she was delivered. Of course it is the latter column of this table which we are tacitly required to analyse. We are expected to notice certain names, either that of Dr. Gordon himself or those of midwives, in connection with several cases of the disease. Thus we find one midwife entered as having attended three cases on days closely following one another, and the same thing we observe to have happened to two others. It cannot be said that this table is altogether conclusive. It is not difficult to perceive that it only contains one part of the evidence which is necessary to make it so. At the time that these cases of puerperal fever occurred in a place like Aberdeen, it must have been, and was, remarked that there were other practitioners and midwives to whom such accidents did not occur, as Gordon mentions in his work; but it was impossible to reduce this important negative evidence into a tabular form. To make up for this deficiency, we have the evidence in another part of the treatise. As one instance, we may take the following:—"Now it may seem remarkable that the puerperal fever should prevail in the new town, and not in the old town, of Aberdeen, which is only a mile distant from the former; that it should prevail at the Printfield, Gillscomston, and the Hardgate villages, in the parish of the old town of Aberdeen, and not in the old town itself. But the mystery is explained, when I inform the reader that the midwife, Mrs. Jeffries, who had all the practice of that town, was so very fortunate as not to fall in with the infection, otherwise the women whom she delivered would have shared the fate of others."

It appears, from this and other parts of his treatise, that Gordon fully appreciated the importance of being able to account for apparent exceptions to the principle he was working out, and that he proceeded with the caution characteristic of his countrymen in venturing to publish the very important conclusions at which he had arrived. It is impossible for any one to analyse Dr. Gordon's treatise fairly, for it is made up of the closest reasoning and the most distinct data. He never supposes anything, but looks carefully to see that his premises are correct, and leaves the reader to draw his own conclusions.

A few extracts from the work will show you what sort of a man he was. Of the nature of the poison, he says simply:—"With respect to the physical qualities of the infection, I have not been able to make any discovery." Of himself, he remarks: "It is a disagreeable declaration for me to mention that I myself was the means of carrying the infection to a great number of women."

He says of typhus, as compared with puerperal fever: "The cause of both is undoubtedly infection; but the two infections are of a very different nature." Of the cure, he says: "There is no disease in which less is done by nature or more may be done by art." As he based his treatment on the view, that the chief effects of the poison were of an inflammatory nature, he directs attention strongly to the benefits which follow early bleeding and purgatives. In his own words: "On this head, I speak with proper confidence, because I speak from experience—the surest test of medical truth. And, as I have already mentioned, I found myself disappointed when I trusted to those means which have been recommended by some authors of considerable respectability; for neither antiseptic nor tonic medicines, nor such as obviate sensibility or irritability, were found effectual."

I must not omit to mention that, as far as the pathology of his time allowed him, Gordon was correct in saying on that subject: "The puerperal fever is a disease which principally affects the peritoneum and its productions, and the ovaria". He distinguishes between "the most effectual means of preventing the infection from being communicated" and the method of "preventing the action of that infection after it has been communicated". He gives sensible hygienic rules to gain the first point, recommending in particular the purification of infected chambers and the fumigation of infected apparel. We can judge, now that three-quarters of a century or more have passed, of the value of this work of Gordon's. It is just the result of that kind of rare combination of originality, energy, patience, and good feeling, which makes us dissatisfied with inferior productions, and is peculiarly characteristic of the leading minds of this country.

We might reflect a little upon the singular fact, however, that every point, except the most important one in this treatise, has been taken up, first by one author and then by another, and all have praised Gordon's work in the very respects for which he least deserved it. We might pause, I say, to reflect upon the question why it is so difficult to get rid of old notions and accept new ones, when they are true and important, or why it happens that error is so much more favourably received than truth when presenting itself as a candidate for support. With what kind of a feeling do we read the conclusion to Gordon's preface? "The benevolent reader must observe with displeasure the ungenerous treatment which I met with from that very sex whose sufferings I was at so much pains to relieve; for, while I was using my best endeavours to mitigate the calamities of many miserable sufferers,

several others were busy in traducing my character, who, prompted by prejudice, very uncandidly proclaimed the deaths and concealed the cures, to raise an odium against my practice."

(To be continued.)

ON THE MEDITERRANEAN COAST OF THE SOUTH OF FRANCE IN ITS MEDICAL ASPECT.

By WILLIAM MARCET, M.D., F.R.S.,

Late Assistant-Physician to the Westminster Hospital and Hospital for Consumption and Diseases of the Chest, Erompton.

THE subject of the present communication has lost, I fear, some of the freshness and attraction it used to possess, from the extent of its literature. My apology in troubling the reader on the present occasion is a desire on my part to show which are the resources of the Mediterranean coast in a medical point of view, and to what extent a winter residence in the sunny South can and will benefit those who suffer from consumption. I shall in no way propose to establish the comparative merits of any particular localities, but endeavour to point out and insist on certain rules which, in my humble opinion, might be useful in the selection of a winter station on or near the Mediterranean coast. A residence of over three winter seasons on the Riviera has given me a fair number of opportunities of judging of its climate and its influence on the progress of disease; hence, in the following communication, I am writing from personal experience.

The usual circumstances inducing, on the part of a medical adviser, a recommendation to winter in the South, will probably be first of all the fact that his patient is invariably worse in winter than in summer. This will apply to chronic cases of phthisis, or cases of threatened consumption, chronic bronchitis, asthma, debility from long continued rheumatism or gout. Many patients apply to us, in some of the usual resorts on the Mediterranean coast, broken down in health from business, anxiety, and mental work. The tide of invalids moving south in November, and northwards again about the end of April, brings with it sufferers of every description, in fear and trembling of cold, which, indeed, their weakened frame has no power of resisting. They leave home upon the first signs of autumn setting in, with the enjoyable prospect of country life in winter, and exercise in the open air, under a bright sun, and without either frost or snow.

It is with consumptive patients that we are mostly concerned, and to that class of sufferers let us now turn our attention.

A certain number of those who come to us for medical advice are anxious to avert an attack of bronchial inflammation, which might lead to the softening of a pneumonic deposit. The applicant may be in apparent good health, strong, able to go about, and fairly full in flesh, although exhibiting a suspicious dulness at one apex, and perhaps some slight laryngitis, attended with a purulent secretion. He or she has been seen by several medical practitioners, and, after obtaining varying opinions, is advised to go south, rather as a means of precaution than with any other object in view. These patients reach their destination often considering themselves in perfect health; and, acting upon that erroneous assumption, subject themselves to many risks, or rather dangers, joining dinners and evening parties, and taking no precautions against the powerful rays of the sun or the sudden cold at sunset. The result is an attack of hæmoptysis, and the disease assumes at once a very serious aspect. If, on arrival, a residence be taken up in a proper locality, and certain rules be strictly observed, the case will, in all probability, do well, the patient returning home in the spring with many a pleasant recollection of his winter season abroad.

Another class of phthisical subjects frequently appear amongst the winter visitors in the South. They have had one or more attacks of hæmoptysis, and are often troubled with more or less shortness of breath, especially on going up hill; still they appear in a very fair state of health. An inquiry into the physical signs of their chest reveals a harsh respiratory murmur, perhaps some fine crepitation in one or both lungs; while the low and indistinct sound of the murmur shows a deficient supply of air to the pulmonary organ. On percussion, no dulness whatever can be detected. Cases of this kind appear to me as instances of deficient nutrition of the pulmonary tissue, with temporary congestion of the lungs. As a rule, patients exhibiting these symptoms do not progress satisfactorily at the seaside, where a return of the hæmoptysis is always to be dreaded; but they do well on the hills which skirt the Mediterranean coast, at an altitude of from fifty to five or six hundred feet above the sea. On condition of their selecting such a place for their winter residence, and observing certain rules of

hygiene, these patients are pretty sure to be free from hæmorrhage; while their strength and general state of health will improve materially. The prognosis in these cases is very uncertain: some of them recover perfectly; others remain in the same state. They reappear in the South year after year, with an account of several fresh attacks of hæmoptysis, but looking much the same as in the previous winter. The physical signs do not vary, the same harsh murmur or crepitation either at the apex or the base being observed.

It may be, however, that the physical signs of simple congestion, or what I imagine to be a state of deficient nutrition, have another meaning, and are symptomatic of tubercular disease, even without the occurrence of dulness on percussion. Harsh breathing and fine crepitation are but a variety of one and the same sound; and fine crepitation at one apex, without any dulness, may certainly be a sign of incipient phthisis. In such instances, the seat of the abnormal sound is an important consideration. If it be heard at the base of one or both lungs, the inference will be a state of temporary congestion; while the same appearance at the apex will rather favour the idea of early phthisis; and here the thermometer comes into use as an important diagnostic means. In case of an increased temperature of the body and quick pulse, the object of the treatment will be to check these symptoms with as little delay as possible. Should they persist, the weight of the body will be observed to fall off rapidly, together with muscular power, the function of nutrition participating in the general state of debility; and diarrhœa setting in will, of course, seriously complicate the treatment of the case. These various changes for the worse may set in without any dulness on percussion of the chest supervening, and without there being much alteration of the physical signs in other respects. Under favourable circumstances, especially if the patient be sent up to the hills, a great change for the better will ensue, the accessions of heat becoming less severe, shorter in their duration, and perhaps entirely disappearing; while the pulse is reduced in frequency. Strength returns; appetite improves; and food is taken with relish, and readily digested. These cases of phthisis return South on the approach of winter, a little thinner, a little more anæmic, than the year before. Still they keep on, till we hear of their fatal termination in summer or in autumn. The progress of the changes in the lungs is very difficult to trace from the physical signs. In one case which I have closely observed for two successive winters, the most careful examination showed no consolidation or softening. The cough was very urgent, accompanied at times with severe attacks of spasmodic dyspnoea; and the patient died in England four months after I had last seen her. Diarrhœa had set in some months before, and I was informed that a cavern in her right lung had been diagnosed when she died.

In some cases, I really do believe that hæmorrhage may be the cause of phthisis, but not unless a phthisical disposition exist in the patient.

We are constantly asked on a first visit, and naturally enough, what amount of benefit we expect a patient to derive from the climate of the South; and how difficult it often is to give a positive answer! Suppose just such a case as that last considered: we must rely on its history, age, hereditary tendency, pulse and temperature, condition of other organs, and general state of health, as the physical signs of the chest belong, perhaps, to a state of simple bronchitis. The age, condition of the organs of digestion, and muscular power, may yield, however, important indications towards the present object. "Age," according to Dr. Pollock (*Elements of Prognosis in Consumption*), "must enter as a distinct element into all our calculations regarding the prolongation of any chronic disease, or the duration of the pauses between the attacks, which we have been noticing." Again, Dr. C. T. Williams (*Med.-Chir. Trans.*, vol. lv) remarks, that the duration (of consumption) is longer in proportion as the age of the attack is later; the retarding influence of age being more conspicuous among males than among females.

I need not insist upon the importance of taking into consideration the state of the organs of digestion and muscular power. A failing in these functions, although perhaps unattended with any change in the physical signs, is invariably an indication of a downward tendency; and the weighing-chair, which tells no tales, will at once detect a falling off in the weight of the body. This last remark not only applies to obscure, but to all cases of phthisis.

We have to consider, finally, the state of pulmonary consolidation with softening, and also that attended with cavities in the lungs. One of the earliest cases I had during my first season in the South (autumn, 1871), being then at Nice, was that of a lady aged about 35, whom I found very much fatigued with the journey from England. There were signs of softening in her lung, and a few days later a cavern had formed. The case, to say the least, did not look promising. There was, however, one satisfactory sign—the absence of a high temperature of the body. Relying on this circumstance, I ventured upon expressing a hope that, as soon as the patient would be rested from her

journey, a marked improvement in her health would take place. Shortly afterwards, in accordance with my advice, she took up her residence on the Cimies hill, about three hundred feet above the sea. The case progressed most satisfactorily, the cavity remaining dry, and showing a tendency to contract. I saw this lady in summer 1873, at Geneva, in the enjoyment of fair health. Thus, as a rule, cases with softening or a cavity do well on the Mediterranean coast on the sea-level, so long as they are free from febrile symptoms; but, should a high temperature and quick pulse set in, together with a rapid loss of weight, then a change of residence must be insisted upon without any delay. This alteration for the worse is much more likely to occur at the seaside than at an elevation of a few hundred feet above the sea; and the probability is, that it will be less marked if the patient be residing at the time in some high locality. But, should the experiment be made of moving down to the seaside while in this febrile condition, with the object, perhaps, of seeking a more cheerful neighbourhood, it will be attended with very great risk, and even perhaps with danger, to the patient.

I do not mean to state that phthisis is not fatal in winter in elevated regions near the Mediterranean coast; but it is certainly less so than in England or on the Mediterranean seaside. In the following case, life was certainly prolonged from a residence on the hills. This lady, aged 40, had been ill for six years. She was in a very low state of health when I first saw her at Nice, on December 4th, 1872; her lungs exhibiting a state of consolidation, with cavities on both sides. I advised her to move up to Cimies. There the pure light air of the hills revived the patient; she improved to some extent, and recovered her spirits, naturally buoyant and cheerful. The winter proved much less trying to her than might have been anticipated; she went out for daily walks in the garden of the hotel without suffering any pain, and hardly conscious that her life could not last much longer. After a time, a Bath chair had to be sent for; then she took to her bed, and in April sank peacefully. No doubt, in this case a residence on the hills preserved life throughout the winter, and succeeded in mitigating pain and mental distress to a considerable extent.

Thus it is that a pure air, possessed of a genial warmth, with a comparatively low barometrical pressure, are beneficial, as a rule, to all cases of phthisis with a high temperature and a quick pulse. Occasionally, these symptoms are arrested; in most instances, they are relieved; and, where a fatal termination cannot be averted, life is either prolonged, or, at all events, carried on under the most favourable circumstances.

Some consumptive patients, however, do well at the seaside. The main character of these cases is the absence of febrile symptoms; they enjoy a fair state of health, although with deficient breathing power. All the other functions are equally weakened, although normal in other respects, thereby re-establishing the balance of energy which should exist between them. I am inclined to believe that the most suitable resort for this kind of cases is some warm sheltered spot on the Mediterranean coast. These invalids live a comfortable painless existence, taking a moderate amount of exercise on the level ground, but unequal to any real exertion.

To the question, Are consumptive people, as a rule, better or worse on the Mediterranean coast at the end of the winter season than at the beginning? I would answer: They are sometimes better, and often much the same, but would probably have been worse had they wintered at home. In general, especially if a residence be carefully selected, consumptive patients undergo at first a marked improvement. The following case may be cited, amongst many others, as an illustration of the favourable change which occurs in health on arrival in the South. A young lady with consolidation and softening in progress in one of her lungs gained over one stone of weight in two months and a half after her arrival at Cannes. She weighed on November 9th, 1874, 7 st. 13½ lb., and on January 23rd, 1875, 8 st. 4½ lbs. It is true that she was in a tolerably fair state of health on leaving home: still this increase in weight is truly remarkable. She now (January 30th) looks the picture of health; but softening has returned, after having been completely arrested for some weeks. An early improvement under proper management often meets with a check from some unaccountable cause in the middle of the season, or about the middle or end of January, when a mild damp weather succeeds to a fine, clear, and bracing atmosphere. Consumptive patients often begin falling off in health rapidly, and it is very difficult to arrest this downward progress. The only plan I know is to insist on an immediate change of residence, moving uphill to an altitude of a few hundred feet above the sea, if possible.

Here is the greatest difficulty we have to contend with. Not only is there a want of accommodation for invalids on the hills near the Mediterranean coast, but an objection, on the ground of such a resi-

dence being lonely and dull, has very often to be overcome. My usual answer is, that the pleasure derived from the consciousness that health is improving will greatly outweigh any drawback consequent on a removal from a centre of social attraction.

With respect to the influence of a winter season near the Mediterranean upon the progress of laryngeal phthisis, I have not met in the South with any instance of its acute form. Several of my consumptive patients, however, had their larynx affected. This extension of the disease was usually attended with little or no pain, although accompanied by more or less discomfort and aphonia. When the aphonia is complete, I question whether the voice can be recovered; when only partial, the voice may improve under treatment. The climate which suits best in cases of laryngeal phthisis is also that most likely to benefit the pulmonary affection. The laryngeal disease, as I have seen it in the South, had nothing of the virulence I often found it to exhibit in London amongst hospital patients. But then it must be remembered that those who can afford to resort in autumn to the mild climate of the Mediterranean coast would also be likely to suffer least at home from laryngeal phthisis.

In my next communication, I shall allude to the subject of climate, and explain, by having recourse to physiological considerations, how it is that stations at some elevation above the sea are those which are most likely to benefit consumptive invalids.

(To be continued.)

IMPERFECT TEETH AND ZONULAR CATARACT:

BEING THE SUBSTANCE OF OBSERVATIONS AT THE
PATHOLOGICAL SOCIETY, MARCH 2, 1875.

By JONATHAN HUTCHINSON, F.R.C.S.,
Surgeon to the London and Royal Ophthalmic Hospitals.

FOR some years past, it has been a matter of general knowledge amongst ophthalmic surgeons that, when children are the subjects of cataract, they usually show also badly developed teeth. I do not know with whom this observation originated, but it is acknowledged in most of our standard works. By some, the malformations have been supposed to be connected with inherited syphilis; and by others they have been associated with rickets and with general defects of development. My object in the present paper is to endeavour to give a little more precision to our knowledge in respect to the coincidence of these conditions. In attempting to do so, it is necessary first to state that I believe that imperfect teeth are, as a rule, met with in connection with one form only of the cataract of childhood. The form to which I allude is known as the "lamellar" or "zonular" form, and is very peculiar. In it, neither the nucleus nor the peripheral part of the lens is opaque; a thin layer of fibres, at a greater or less distance from the nucleus, and completely surrounding it, being alone involved. The defect is compatible with very fair vision, and is often not detected until the child attempts to learn to read, sometimes not even till adult life. It is, I believe, almost invariably symmetrical, and is in a large number of cases quite stationary. It is not associated with any special diathesis, and it is very exceptional to meet with it in more than one member of a family. All these facts would suggest that it is probably the record of some temporary disturbance in the nutrition of the lens, rather than the result of any permanent peculiarity in the patient's state of health. It may be added, in support of this view, that lamellar cataract has not, I believe, ever yet been recognised at the time of birth, but is generally discovered at earliest during the first few years of the child's life. The congenital cataract belongs probably to a wholly different category, and is not lamellar. Whilst the congenital forms are often attended by other defects in the development of the eye, and with very imperfect vision, the lamellar opacity is, I believe, as a rule, the only defect to be found in the organ.

I must next describe the kind of defect in the development of the teeth which it is usual to meet with in connection with these curious cataracts. It is wholly different from that met with in congenital syphilis, and consists not so much in alteration of the form of the teeth as in defective development of the enamel. It is very often met with in association with the malformations which characterise hereditary syphilis, and hence probably some of the confusion which has resulted. The incisors, the canines, and the first molars, are the teeth which suffer most; and as a rule, with but very few exceptions indeed, the bicuspsids escape entirely. The contrast between the clean, white, smooth enamel of the latter, and the rugged discoloured spinous surface of the first molar, is often very striking. The first molars may, indeed, be counted as the test teeth as regards this condition: just as the upper

central incisors are in that which is due to syphilis. In these teeth, it occurs equally in both jaws. They are sometimes affected when all the other teeth escape, and I believe they never escape when the others suffer. I have been speaking throughout of the *permanent* set of teeth; for here, as in syphilis, although the temporary teeth often show unsoundness, they do not, I believe, exhibit any changes upon which it is safe to rely for purposes of diagnosis. The drawings which I hand round will convey a good idea of the kind of defect which is meant. They show the incisors and canines in various degrees pitted, dirty, and broken, often presenting very sharp edges, and sometimes almost spinous. In some cases, a horizontal line crosses the crown of the incisors and canines at one level; the part of the tooth below the line being narrower from before backwards, sharp, and broken. Non-development of enamel and erosion of the exposed dentine appear to be the essential features.

In the first molar, it is usually the surface alone which is affected, the sides of its crown being often covered with good sound enamel, whilst its surface is denuded, brown, and rugged.

I must next state that, although lamellar cataracts are generally attended by defect of teeth, yet the coincidence is not invariable. I have before me the notes of three cases, characteristic examples of lamellar cataract, in which the permanent teeth are stated to have been quite sound. The converse statement, that these peculiarities of teeth are often met with in patients who have not lamellar cataract, is a fact with which all will be familiar. In the face of these facts, it becomes difficult to entertain the hypothesis that there is any direct correlation between the nutrition of the lens and that of the permanent teeth, by which the coincidence adverted to might be explained.

Some years ago, Professor Arlt of Vienna made the important clinical observation, that those who suffered from lamellar cataracts usually had the history of attacks of convulsions during early periods of infancy; and my belief is, that it is in connection with this fact that the dental defects are to be explained. As the result of a considerable amount of inquiry amongst those whose teeth presented the peculiarities described, my conclusion is, that the defects generally result from attacks of inflammation of the gums occurring in early infancy; and that, amongst the causes of such stomatitis, mercury holds by far the chief place. There seems reason to believe that, in a large number of cases in which infants suffer from fits, mercury is given, and not unfrequently in large and repeated doses. I believe that it also enters into the composition of some of the most popular teething-powders.

My suspicion is, then, that when malformed teeth are met with in connection with cataract, they prove only that the patient has taken mercury in infancy, at a period when the enamel of the teeth was undergoing calcification. On this supposition, we have a ready explanation of the order in which the teeth suffer, since it is precisely that of their priority of development. A very considerable collection of facts justifies me in the inference which has just been stated. Of late years, in cases of lamellar cataract, I have always made it a rule to examine the teeth, and to inquire as to the history of fits, and as to the measures of treatment to which the patient was subjected in infancy. The connection between fits and cataract seems almost universal; that between cataract and malformed teeth general, but with marked exceptions; whilst, when the cataracts and malformed teeth are found together, it is very exceptional, provided the mother of the patient can be seen, not to obtain testimony as to the treatment of the fits by means of mercury. Of course, in some cases, the evidence on the latter point is either not forthcoming, or imperfect, but in many it is most strong.

I wish it to be distinctly understood that nothing which I have stated above has any claim to novelty, excepting, perhaps, the attempt to explain the connection between the different conditions mentioned. It is more than ten years since Arlt published his observations respecting the connection between fits and lamellar cataract; and, exactly ten years ago, Dr. Davidsen, then a student at Zurich, embodied the views of Professor Horner of that university in an inaugural thesis, in which most of the questions which I have discussed are entertained. I was not aware of the existence of this thesis (which was never published) until a few months ago, when it was obtained for me by the kindness of my friend Dr. S. L. Frank. Dr. Davidsen arrives at conclusions very similar to my own on most subjects, excepting the possible influence of mercury in producing the deformities of the teeth. This he does not even discuss, but speaks throughout of the dental defects as characteristically those of rickets. His table of cases does not place the coincidence between convulsions and lamellar cataract in such a strong light as do the facts collected by Professor Arlt and my own. It is obvious, however, that a considerable margin must be left here for cases in which no trustworthy history of the patient's infancy was ob-

tainable. Of these, Dr. Davidsen makes no mention, but he appears to count all cases in which no history of fits was given him as if their absence had been proved; and, as most of his patients were adults, a serious source of fallacy in the calculation of percentages is here introduced.

Professor Horner has favoured me, through Dr. Frank, with the statistics of seventy-eight cases observed by himself. In these, he found a history of convulsions in 76 per cent., deformities of the teeth in 85 per cent., asymmetry of the head in 35 per cent., imbecility in 2 per cent., and rachitic malformations of the extremities in 4 per cent. The remark which I have just made as to the difficulty of obtaining accurately the history of the patient's infancy applies also to these percentages; and the 76 per cent. with history of convulsions must be distinctly understood to mean that, in this proportion, convulsions were proved, whilst probably they were by no means disproved in all of the remainder. Professor Horner, who has given great attention to the subject, still believes in rickets as the cause of the dental malformation, and does not think that the hypothesis of mercurial treatment as the cause would hold good in Switzerland.

Although it seems to me probable, as already stated, that the convulsions stand in the relation of cause to the cataract, and the mercury given for the convulsions in that of cause to the dental malformation, yet I by no means wish to imply a belief that these associations are invariable. Certain apparent exceptions occur which require further investigation before we are justified in entertaining confident opinions on these points. Thus I have several times seen sets of teeth which I should have considered characteristically mercurial, in cases in which all history of drug treatment in infancy was denied; and it must be admitted to be quite possible that other forms of stomatitis will produce similar results. There are also certain rare cases in which zonular cataracts are met with in several members of the same family in the same or in different generations, and in some at least of these I believe that there is no history of convulsions, and that the teeth are not malformed. Upon the peculiarities which attend this class of cases, however, more detailed information is required.

In reference to the suggestion of the Zurich investigators, that the peculiarities in the teeth, in the skull-bones, and in the general development, are all due to rickets, I must be allowed to say, that it is as yet wholly unproved. I am not aware that any author has described what are so freely spoken of as "rachitic teeth", if that term be applied, as it is by Dr. Davidsen, to the permanent set. Professor Vogel of Dorpat, in his work on *Diseases of Children*, states, in reference to the effects of rickets on the teeth, that, "as the disease disappears before the second dentition commences, these phenomena are not observed in the permanent teeth". Yet it is upon the state of the permanent teeth almost solely that the diagnosis of rickets in the Zurich *clinique* is based; for in only 4 per cent. did Professor Horner find evidence of rachitic malformation in the extremities. The irregular formation of the skull, defects in symmetry of the face, and mental peculiarities when present, are perhaps quite as easily explained by reference to the preceding attacks of convulsions as by the hypothesis of rickets.

By way of summary, I think it may be stated—

1. That it is exceptional to meet with lamellar cataracts, excepting in association with an imperfect development of the enamel of the teeth; but that definite exceptions, in which the teeth are quite perfect, do occur.
2. That the kind of defect observed in the teeth consists in absence of the enamel, and is shown in the incisors, canines, and first molars of the *permanent* set, to the almost invariable exemption of the *pre-molars*. That, for purposes of diagnosis, the first molars are by far the most important, and may rank as the test teeth, since they not unfrequently show the defect when the others escape.
3. That it is highly probable that the defects in the development of the teeth are usually due to the influence of mercury exhibited in infancy; although it is quite possible that other influences, attended perhaps by inflammation of the gums, may occasionally produce similar results.
4. That teeth of the kind alluded to are met with very often in persons who are not the subjects of zonular cataract.
5. That the very important observation made by Arlt, that the subjects of lamellar cataract have usually suffered from convulsions in infancy, is fully borne out by further examination; and that it is very unusual to find lamellar cataract without such history.
6. That it is probable that there is a direct connection between the occurrence of convulsions in infancy and the development of lamellar cataract.
7. That, whilst there is every reason to believe that the defective teeth which are met with in connection with lamellar cataract are the

results of mercury, the evidence seems opposed to the belief that the lenticular opacity is also due to the influence of the drug. The great frequency of mercurial teeth without lamellar cataract, and the not very infrequent occurrence of lamellar cataract without mercurial teeth, are opposed to this view.

8. That the very frequent coincident occurrence of lamellar cataract with defective teeth, is to be explained by reference to the frequency with which mercury is given for the treatment of convulsions in infancy.

9. That there is no reason whatever for supposing that lamellar cataracts have any connection with hereditary syphilis.

10. That, whilst it is certainly true that lamellar cataracts are commonly met with in young persons who show general defects of development, short stature, ill-shaped heads, defective intellect, dwarfed lower jaws, or other physiognomical peculiarities, yet there is seldom any proof of the existence of rickets; whilst it is quite possible that the peculiarities mentioned may be due to the disturbance of the nervous system in infancy in connection with the convulsions.

11. It is very important to distinguish between mercurial teeth and syphilitic teeth, and the peculiarities presented by each usually render this easy; the two are, however, as might have been expected, not uncommonly met with together.

THE CLINICAL THERMOPILE.

By T. CLIFFORD ALBUTT, M.A., M.D.,

Physician to the Leeds Infirmary.

LEISURE, as Mr. Seymour Haden says, presents itself to the busy man in an ever diminishing quantity; and hence it is that I have long deferred the publication of my experience with a thermo-electric apparatus closely resembling that described by Dr. Lombard in a recent number of this JOURNAL. In the years 1866 and 1867, I was engaged, with the assistance of Messrs. Harvey and Reynolds of Leeds, in perfecting a clinical thermometer, which, being portable, should find its way into general practice. I was also wished to obtain an instrument to record surface-temperatures; and to this inquiry I gave a good deal of time. Mercurial thermometers for this purpose gave very imperfect results. Instruments were made with button bulbs, with spiral bulbs, with bulbs guarded above by non-conductors, and so forth; but little came of them. I, therefore, turned my attention to a thermo-electric apparatus; and Messrs. Harvey and Reynolds constructed for me in 1868 an instrument far less perfect and elegant, but substantially the same as that of Dr. Lombard.

It consisted of piles attached to handles, exactly identical with those figured by Dr. Lombard, of a rheostat, and of a galvanometer. The piles were of bismuth and antimony, but they resembled those figured so closely as almost to startle me when I saw them represented. The rheostat was far inferior to Dr. Lombard's, and the galvanometer less perfect in detail. I am told by physicists that my instrument was as good as could be had at that time; and so I must think, for I constructed it with the help and advice of the first physicists of the day. I am also told that much of the excellent detail in Dr. Lombard's calculations was scarcely possible before the date of some publications by Professor Tait, of which, I regret to say, I know little. My galvanometer was provided with stops to prevent deflections of the needle beyond the points which give true indications. But, although I found it easy to calculate relative temperatures with great accuracy, I found a difficulty in expressing these accurately as absolute temperatures in the centigrade or any other scale.

I have had my machine, such as it is, in work since 1868, and have gained a great deal of experience with it. For some time, I used it in the wards of the infirmary; but the connecting wires, etc., made the instrument too cumbersome for ward-work. Still, I made many very valuable observations in the wards, which I have supplemented in my chambers. The general outcome of this is, that even a very imperfect instrument is thoroughly trustworthy as a means of recording surface-temperature, and is very easy to work and to keep in order. As to results, I fear I cannot say much that is of high clinical value. Perhaps the most valuable results I have obtained are the relations between superficial and internal heat. I have found that there is little, if any, constant ratio between the two. I have found superficial heat to ascend with the increase of internal heat; I have found it stationary during such ascent; and, on the other hand, I have found it to descend, making the contrast between the two greater and greater. Again, I have found that the ratio between internal and superficial heat varies with the parts examined. While internal heat is fairly constant, superficial heat is very variable. I have often found superficial heat rising on the abdo-

men while it was falling in the extremities, facts which admit a tolerably probable explanation. I have also made some curious observations upon the localities of sweating in hectic and similar states. Some patients sweat on the limbs, others on the trunk, fore or back, others about the head or neck; and I hope to be able to correlate these observations with other facts. The chief point, however, which I have before me at present is, to say that some outbreaks of sweat are preceded by a rise of surface-temperature, while others are preceded by a fall. During the sweat, a fall of surface-temperature is nearly constant. But, not to occupy too much space, I may go on to say that I have not found that inflammation as such raises local temperature, but that local afflux of blood does so raise it, whether this be a congestion or a blush. Finally, in nervous diseases I have used the piles more, perhaps, than in any others, with very various but no definite results. I have found that in neuralgic districts the surface-temperatures sometimes rise and sometimes fall, that in other cases a rise may precede a fall, while in a fourth class a fall precedes a rise. Upon all this, I must dwell more fully another time. In palsies, the surface-temperatures are often very interesting, not clinically so much as physiologically, but I have not yet obtained any constant results. As to railway cases, the more I see of them, the more I find them unfit for scientific investigation; and I have found that common clinical sense is a far more useful organ for us in them than minute instrumental research.

CASE OF COMPOUND DEPRESSED FRACTURE OF THE CRANIUM, WITH LACERATION OF BRAIN-SUBSTANCE, CAUSED BY A BLOW FROM A QUOIT.

By R. W. FORSAYETH, Surgeon 95th Regiment, Fleetwood.

ON the morning of September 12th, 1874, as I had concluded my visit and was about to leave the hospital, I met in the passage a man bleeding from a wound in the head. He was brought in by two comrades, but was quite able to walk without their assistance, and seemed so little affected by the injury he had received, that at first sight I was inclined to take a trivial view of the case. However, I ordered him to be placed in bed; and, being provided with sponges and tepid water, proceeded to examine the wound: a deep laceration, triangular in plan, severing the scalp for a couple of inches, and situated at the anterior superior border of the left parietal bone. Considerable oozing of blood was going on, which obscured the view; so, introducing my index finger as a probe, I distinctly felt a deep oblong depression, bordered by sharp edges, and, at the same time, was dismayed to see small particles of brain-substance escaping with the blood from the wound. At this time, no other symptoms existed to denote the serious nature of the injury. Countenance, pupils, pulse, respiration, and consciousness were alike unaffected. The patient himself also seemed to think it of little consequence.

Notwithstanding this apparently quiescent state of affairs, on consideration, I determined to operate as soon as possible for the removal or elevation of the depressed bone, and not to await the supervention of symptoms of compression, which, from the serious nature of the injury, I felt certain would sooner or later set in. As I had no military medical colleague on the spot, I sent for Dr. Orr of Fleetwood to assist and advise me; and, while waiting his arrival, learned the history of the case. The man was playing a match at quoits. Two pins, or marks, being placed in the ground at a distance of twenty-one yards, he and his opponent threw from one end of the space thus marked out, his partner and opponent from the other, alternately; using six-pound quoits. On one occasion, thinking that the quoits had all been delivered from the opposite end, he ran in and stooped to raise them from the ground. Simultaneously with his movement, another quoit was thrown by one of the players at the far end; and, as he bent towards the ground, it struck him on the head. Hurlled to the earth, he remained unconscious for a few seconds; then, being raised by his comrades, behaved as if drunk, resisting their endeavours to lead him to the hospital; but, in a few seconds more, he became quite himself again, and walked thither with little or no assistance.

About 3 P.M., Dr. Orr arrived. The patient's state was then indicative of commencing mischief. He was inclined to sleep, breathing was more laboured, and the pulse slower and weaker. Dr. Orr consequently, after examining the injury, agreed with me that immediate action was desirable. As the man was unable to bear the pain caused by handling the wound, Dr. Orr kindly administered chloroform; and,

when anæsthesia supervened, I proceeded to expose fully the seat of injury; the nature of which will be understood by reference to the diagram.

The shaded surface H, K, L, D, F, represents the depression, the deepest part of which was at K L, where the lacerated brain-substance was visible. Some small fragments of bone were removed from this and the superior angle of the fracture, by means of a small dental elevator and a dressing forceps; but the greater portion of the depressed bone was in one piece, and its sides so overlapped by the edges of the skull H K, and F D, that a purchase for the elevator could not be obtained. Observing a line of simple fracture running from A to B, I connected it with the edge of the depression, to which it was parallel, by two saw-cuts F E, and D C; intending to remove the oblong piece thus marked out, and thereby be enabled to expose the edge of the fragment in front. After sawing through the outer table, I found it quite detached from the inner, and removed it. Then the outer table of the depressed portion, H, F, K, L, D, also came readily away. The whole of the inner table from E C to H K, was found to be depressed *en masse*; the curve commencing at the line F C, and becoming greater as it advanced forward, the anterior free margin was deeply fixed under the edge of the sound bone at H K, and quite immovable. Therefore, making two saw-cuts H G and I K, which intersected, I removed the triangular portion of solid bone included. The elevator was then inserted under the depressed edge now exposed, and the portion of the inner table corresponding to the space H, F, D, K, came away, detaching itself from the remainder at the line I D. Here, the elevator being again applied, the rest of the bared inner table was raised to its normal level.

Some small fragments were then extracted from the brain-substance, into which they had been driven by the blow of the missile, at the corner K L. No others being apparent or perceptible by cautious and limited investigation, the wound was dressed with lint and cold water. When the patient had recovered from the effects of the chloroform, a saline purgative was administered.

No bleeding of any consequence occurred during the operation; the small vessels divided were readily controlled by torsion. Great care was taken to dissect the periosteum from off all bone removed, so as to preserve every chance of eventual reproduction.

7 P.M. He felt better. He was quiet and inclined to sleep. He could not retain the saline draught. The skin was natural, and the pulse fuller, and of more normal velocity. He was ordered to have five grains of blue pill.

September 13th, Morning. He passed a quiet night. Pulse 75, rather labouring. The pupils and skin were natural. He complained of no pain. He stated that he felt easy, but was unable to eat anything. Tongue whitish. He vomited the pill, but retained a little tea. The wound was healthy looking; the cavity was filled with a sanguineous clot. While I was in the room, he yawned, and turned about two or three times in a listless way, but answered all questions rationally, and in his natural manner. He was ordered to have an effervescent saline draught, as the bowels had not been moved since the operation.

Evening. He took some arrowroot during the day. The saline was rejected, but an enema of castor-oil and turpentine produced a satisfactory motion. Dr. Orr kindly visited him with me; and calomel in two-grain doses every second hour was prescribed.

September 14th. He slept fairly. He had but little pain in the head. The pupils continued natural; but the conjunctivæ were slightly suffused. He could take no food other than milk and arrowroot. The calomel was omitted after twenty grains had been taken.

September 15th. The bowels were opened freely this morning. Pulse 64, soft, and regular. Pupils natural. Stomach settled. He had had a good night. The wound was healthy looking, and presented no appearance of fungus. The diet still consisted of milk, etc., but little of any solid was attempted, as he expressed great disinclination for food, and I did not desire to press him. Some Condé's fluid was ordered to be added to the water used in dressing the wound.

It is unnecessary further to follow the daily notes of this case. The man continued to improve without a single bad symptom. I was very apprehensive of the occurrence of fungus cerebri, but at no time was there any disposition towards its production. The wound filled rapidly with healthy granulations, no exfoliation of bone taking place, and cicatrization was complete on November 25th. The man was retained under observation for some time further, and finally discharged to duty on December 3rd.

The only abnormal symptom which presented itself during the case was considerable weakening of the heart's action. Soon after the operation, the pulse at each wrist became almost imperceptible, though the heart's sounds and action were normal; and no faintness, or coldness of the extremities, was complained of. Even up to the date of his discharge, the pulse at the wrist continued extremely feeble, but the man looked and felt as well as ever; and was, long before I discharged him, anxious and able to go to his duty. On discharge, the cicatrix was perfectly firm, and did not yield in the slightest to pressure, as if the bony gap had been quite refilled.

I cannot but think that the careful preservation of the periosteum had much to do with this good result.

OBSTETRIC MEMORANDA.

OVARIAN DISEASE: TAPPING: CURE: SUBSEQUENT ACCOUCHEMENT.

MRS. B. consulted me five months after her marriage as to her condition, which, to outward appearance, seemed to be that of a woman far advanced in pregnancy. As she had some doubt on the subject, I proposed seeing her at home for examination. The non-existence of pregnancy was not difficult to diagnose, and, for confirmation of my opinion that the swelling was ovarian, I sent her to Mr. Cadge, who kindly offered, if it met my views, to take her into the hospital. The patient herself was unwilling, and time passed on, till the swelling of the body had increased so much, her general health was so impaired, her emaciation had become so great, and her breathing so distressing, that relief in some way was urgent. Mr. Cadge being absent for a season, Dr. Beverley saw her in consultation with me, and it was determined that tapping should at once be resorted to. The result was the emptying of the cyst of three and a half gallons of a greenish yellow, somewhat glairy fluid. The usual compress with the flannel roller was applied afterwards. She recovered without an untoward symptom, and no reaccumulation of fluid took place. I visited her some months afterwards, and found her so hale and hearty, that I did not recognise her, and she had to assure me of her identity. Four months since, she again consulted me, and this time there was no doubt of her pregnancy. She was delivered of a healthy child on February 2nd, after a natural labour of twelve hours' duration, and, up to the present date (25th), has made a good recovery. The tapping took place in July 1872.

Wm. H. DAY, Norwich.

A NEW FORM OF INDIA-RUBBER BALL-PESSARY.

HAVING experienced great difficulty in the management of cases of displacement of the uterus, from the pain occasioned by pessaries made of hard material, and from the escape from the vagina of ordinary India-rubber pessaries, I procured an India-rubber ball, hollow, about the size of a small orange, with a wall about half an inch in thickness, having a hole about the size of an undried pea on one side, and capable of expanding itself, and of overcoming considerable resistance in this act. I expected that this instrument would readily resume its original size in the pelvis after having been diminished in bulk by efforts of coughing, defecation, etc.—causes which lead to the expulsion of ordinary air-pessaries.

Edw. -

A case suitable for its trial occurred in my practice six weeks ago in Mrs. D., aged about 56, who had suffered from procidentia uteri for several years, but who was in other respects in good health. Mrs. D. is a thin active woman, who has had several children, and whose ailment has never obliged her to wholly relinquish her employment, which is that of attending to a village grocer's shop and household work; but it has often compelled her to go to bed early in the afternoon, on account of pain and discomfort at the bottom of her body and leucorrhœa. On examination, the cervix uteri was found one inch outside the os vaginae, and was the seat of superficial ulceration. The organ was returned without difficulty; complete rest in the recumbent posture, the use of an astringent lotion, and tonic medicine, were prescribed. At the expiration of a fortnight, the ulceration of the cervix had healed, and the leucorrhœal discharge had almost ceased; but the protrusion of the cervix uteri outside the vagina occurred whenever my patient assumed the erect posture. At the expiration of another fortnight's rest, her condition had not materially altered. I, therefore, again returned the cervix uteri to its proper position, and introduced the pessary above described, having first completely emptied it of air by forcible pressure; and, after its introduction, I expanded it with air to its utmost extent by means of a syringe. My patient has now worn this pessary above a fortnight with the most complete satisfaction. The cervix has never protruded. The leucorrhœa has not returned. The pessary has never become displaced. No pain or discomfort has occurred, although Mrs. D. has attended to her ordinary employment.

PALEMON BEST, M.B.Lond., Louth, Lincolnshire.

CLINICAL MEMORANDA.

POISONING BY COKE, FROM ITS USE FOR DOMESTIC PURPOSES.

ON February 19th, I was called to two cases of poisoning from coke, which was being used that day in the still-room of a gentleman's house for the preparation of marmalade. In the first instance, the still-room maid, whose duty it was to manufacture this preserve, after having inspired the vapour for a short time, was seized with giddiness, headache, and vomiting; but, as she was a chlorotic girl of about 17, and had been ailing for some time previously, little attention was paid to these symptoms by her superior domestic, and she was simply removed to another room, where she gradually rallied, the whole symptoms, indeed, being attributed to the intense heat. The housekeeper, who had but recently recovered from an attack of acute bronchitis, now thought she might complete the preserving of the marmalade herself; but she also was soon affected with the same symptoms, accompanied with the sensation of great weight in the head, ringing in the ears, and a strong tendency to sleep. Following these, her muscular power seemed to be diminishing, and, taking advantage of this, she thought she had better ring the bell for some one to come, which she had barely time to do, when she fell as if struck to the ground. On my arrival, which was almost immediately, I found that the steward had carried her into her own room, and had her placed on a chair, while the breathing was difficult and stertorous, and the action of the heart very feeble. The countenance also was livid, especially the eyelids and lips. Under these circumstances, there was no chance at that time of getting a history of the case, and consequently she was treated as symptoms presented themselves. We had her placed on her back, with the head somewhat elevated, and bottles of hot water applied to the feet, while stimulants were employed in the form of frictions, and aromatic spirits of ammonia held to her nose; under which treatment she recovered. Both patients, after their recovery, alluded again and again to the sensation in the head and the tendency to sleep; so that these, coupled with the other symptoms which were manifested in the case of both patients, leave little room for doubt, I think, that they were cases of poisoning by carbonic acid gas from the burning of this coke.

At certain seasons of the year, I have reason to believe we may be called upon not unfrequently to treat cases similar to that described, without knowing the direct cause at the time; and, as we already know that a weak solution of potash or lime, applied by means of a handkerchief or a piece of flannel to the mouth and nostrils, allows the oxygen to enter the lungs, it has suggested itself to me that possibly some of our scientific mechanicians might devise a respirator or other apparatus to be worn when necessary, which would undoubtedly in course of time become a *sine quâ non* for the kitchen and still-room.

ROBERT TORRANCE, L.R.C.S.E., Matfen, Newcastle-on-Tyne.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

ST. MARY'S HOSPITAL.

TWO CASES OF PARALYSIS OF THE SERRATUS MAGNUS.

(Under the care of Mr. EDMUND OWEN and Mr. S. J. KNOTT.)

THE nature of the lesion giving rise to that peculiar position of the shoulder-blade, which was formerly described as a "dislocation of the scapula", does not seem to have been understood until it was explained by Duchenne.

Liston, in 1832, in his work on *Surgery*, speaks of "luxation of the scapula" as being caused by the inferior angle of the bone slipping from under the upper border of the latissimus dorsi; and, having briefly described a condition of the parts analogous to that which is given below, he suggests treatment by bandaging the chest. He does not, however, speak very cheerfully of the result, but says that matters will gradually settle down, and that little inconvenience will result.

Now, if the prominence of the vertebral border and of the inferior angle of the scapula, which is characteristic of the affection, were really due, as Liston supposed, to the bone slipping from beneath the latissimus dorsi, caused "by raising the arm above the head to an unusual extent", the symptoms would *suddenly* supervene, whilst the cure, when effected, would also be rapid. The lesion could hardly be bilateral without there being a decided history of violent exertion or injury. Moreover, if it were the office of the latissimus dorsi to strap down the shoulder-blade, it would probably take a firmer and more secure attachment to that bone; and its position over the angle would be more constant than observation in the dissecting-room shows it to be. The muscle which binds the shoulder-blade to the chest is the sheet-like serratus magnus, which, attached to the ribs and to the costal aspect of the base of the scapula, is ever ready under stimulus to approximate these parts.

The following reports show a *gradual* invasion of the symptoms (in one case on both sides), with a gradual termination in recovery.

In February 1873, a married woman, aged 39, became an out-patient at St. Mary's Hospital, complaining of pain and weakness in the right shoulder, which had been coming on during the preceding six months. There were also some pain and tingling in the middle of the back, and along the costal attachment of the serratus magnus. She attributed her troubles to the fact of her having been for some years in close attendance upon an old lady, whom she used to rub for chronic pleurisy. At last, the arm became so powerless that she could only just manage to dress herself. Her mistress then sent her to seek the advice of one of that anomalous class of unqualified consultants, of recent growth, called "surgical mechanicians", who proceeded to remedy the weakness by an apparatus, which proved to be as useless as it was, no doubt, expensive.

When she came under observation, there was great prominence of the vertebral border and of the inferior angle of the scapula, and the finger could be pushed up under the venter for fully two inches. The deformity was greatly increased when the patient endeavoured to raise the arm above the head, for the muscle so much concerned in accomplishing that action, the lower part of the serratus magnus, being out of working order, the trapezius, the levator anguli scapulae, and the rhomboids were called upon to support the extremity; whilst the weight of the limb, which was unopposed below, caused the inferior angle of the scapula to be rotated upwards and backwards. When the limb was supported by the hand, these muscles were set at rest, and their prominence disappeared. Faradisation being deemed advisable, the patient was placed under the care of Mr. Knott, who saw her, on an average, twice a week for the next two months. When one pole of the battery was placed in the root of the neck, near the origin of the nerve of Bell, whilst the other was applied along the costal attachment of the serratus magnus, the scapula was at once dragged into its proper position, and there remained so long as the currents were passing. Marked improvement followed each application of the battery; the pain and deformity gradually disappeared; and, the usefulness of the arm having been restored, the patient left off attending at the end of April.

The other case was that of a boy, whose constant amusement had been derived from the skipping-rope. He was a thin, sickly looking fellow, of eleven years, when he came under treatment, in April 1873. There had never been any pain or weakness in the shoulders, and it was only by accident that his mother discovered that both his shoulder-

blades were growing out. For two months after this, the deformity was allowed to go on increasing before advice was sought. The patient was exhibited by Mr. Owen at a meeting of the Harveian Society, when the bilateral deformity was very perceptible. The right scapula was, however, more prominent than the left, and the fingers could be pushed up beneath the inferior angle nearly half way to the glenoid cavity. The boy was certainly able to raise his hands high above his head, the deformity increasing the while. This action was, no doubt, accomplished by the action of those higher scapular muscles enumerated above, with the addition of the supraspinatus and deltoid. A large flabby bundle of the serratus magnus could be picked up between the fingers and thumb, ascending from the lower true ribs; the ribs had dropped considerably; and a tap from the finger set up a peculiar quiver in the muscle. Faradisation had the same effect upon this patient as upon the other, at once bracing up the scapule into their proper position; but, as the boy lived at Peckham, his attendance was less regular, and his improvement less rapid than in the other case; nevertheless, he made a steady progress to recovery.

MANCHESTER ROYAL INFIRMARY.

TRAUMATIC RUPTURE OF LEFT COMMON FEMORAL ARTERY;
LIGATION OF THE TORN ENDS: RECOVERY.

(Under the care of Mr. BOWRING.)

[Communicated by Mr. JONES, Pathological Registrar.]

J. R., AGED 30, collier, was admitted into the Infirmary June 15th, 1874, and gave the following history. Five weeks before admission, he was at work in a coal-pit, assisting to push trucks up an incline. He was violently exerting himself, with legs extended and feet fixed, when he heard a snap in the left groin. This was followed by pain and a small pulsatile swelling. He, however, continued at his work for some days. At the end of a fortnight, he consulted a surgeon, who tried in vain to control the swelling. The tumour did not increase very rapidly, and at the end of a month it was only the size of two closed fists; but, as he was being removed to the Infirmary from his home, which was at some distance, the limb became enormously distended.

On admission, a large semifluctuating elastic swelling was found in the upper part of the left thigh, reaching upwards beyond Poupard's ligament, and downwards nearly to the knee. There was no pulsation or bruit in the tumour, and no pulsation in the arteries of the leg; the latter was much swollen and oedematous.

June 16th. At a consultation this afternoon, a diagnosis of ruptured artery was agreed upon, and it was determined to cut into the tumour and secure the divided ends of the artery. After the administration of chloroform, and the application of Lister's aortic tourniquet, an incision in the course of the femoral artery was made. Large clots were cleared out, and the ends of the torn artery were discovered at least an inch apart; these were secured by catgut ligatures. The vein was intact. The edges of the wound were brought together by metallic sutures, and the wound dressed with dry lint and limb wrapped up in a flannel bandage.

June 17th. He slept from the time of the operation last evening (7 P.M.) till 1 A.M. this morning; was restless till 3 A.M.; then had fifteen minims of Battley's solution, and slept three hours. He took plenty of milk, and an occasional egg, together with ten ounces of brandy in the twenty-four hours. Temperature 100; pulse 98, quiet.

June 18th. He had a good night after the administration of an opiate. There was very little pain. Pulse 130, bounding; temperature 100.4; skin hot and moist. The wound was dressed; there was a little sanious discharge.

June 20th. Pulse 128; temperature 100.1. He passed a restless night, and complained of shooting pains down the thigh and leg. Most of the sutures were removed. He had fish for dinner. The tongue was clean and moist. The wound was syringed out with Condy's fluid several times during the day, and dressed with warm spirit.

It is hardly necessary to continue the daily report; suffice it to say, that the patient made an uninterrupted recovery, and that, when discharged, at his own request, on July 30th, the wound had almost entirely cicatrised over. The patient presented himself at the Infirmary about the middle of December. The limb was perfectly strong, and he was able to walk a long distance without any inconvenience.

MR. WILLIAM HEWITT has been presented with a life-size portrait of himself, painted in oil, in appreciation of his valuable services and general kindness to the members during a period of fifteen years, as surgeon to the Court Pride of North Walsham, No. 3308, of the Ancient Order of Foresters, North Walsham.

SELECTIONS FROM JOURNALS.

ANATOMY.

COMPARATIVE LENGTH OF THE SPINAL CORD.—C. Fehst (Inaugural Dissertation, 1874) found that, in bodies of twelve adult men, the average length of the spinal cord was 45 centimètres (nearly 18 inches, or 1.476 feet); that of the vertebral column, 73 centimètres (28.7 inches); the average length of the body being 168.6 centimètres (a little above 5 feet 6 inches). In twelve women, the measurements were respectively 43.8 centimètres (17¼ inches or 1.43 feet), 68.2 centimètres (25¼ inches), and 157 centimètres (5 feet 1½ inches). Thus, in men, the length of the spinal cord was, to that of the vertebral column, as 1 : 1.62, and to that of the whole body as 1 : 3.76; while in women the ratios were 1 : 3.6 and 1 : 3.58. Except in one case, the spinal cord terminated in the men either at the middle or at the lower border of the first lumbar vertebra; in the women, it reached in three cases to the lower end of the first, and in three to the lower end of the second lumbar vertebra, and in the remaining six cases to the middle of the second. Hence the first lumbar vertebra in men, and the second in women, may be assumed as the lower limit of the cord. The conus medullaris (lumbar enlargement) extended further down in women than in men. In children, the sexual difference in the length of the spinal cord and in its relation to the vertebral canal is almost entirely absent. In the bodies of male children between one and three months old, the ratios of the length of the spinal cord to the vertebral canal and to the length of the body were 1 : 1.59 and 1 : 3.26; in female children, 1 : 1.58 and 1 : 3.20. In both sexes, the conus medullaris ended at the lower border of the second lumbar vertebra. Additional measurements on the bodies of older children lead to the conclusion that the relations between the length of the spinal cord and of the vertebral canal correspond to those of adult females, and that in males there is a growth of the vertebral canal in greater proportion than of the spinal cord.—*Centralblatt für Chirurgie*, No. 18, 1874.

SURGERY.

TREATMENT OF THE WOUND AFTER EXTIRPATION OF TUMOURS OF THE BREAST: METALLIC SUTURES.—Dr. Vibert of Puy describes in the *Lyon Medical*, No. 26, the following process, which he has employed with advantage during the last eight years. When the tumour has been removed, and all the arteries taken up with the help of thick *serre-fines*, a series of fine silver wires are passed at a distance of about four-fifths of an inch, or less, from each other, by a slightly curved packing-needle, about six inches long, and as thick as a large knitting-needle. The needle is inserted about four-fifths of an inch from one of the lips of the wound, perpendicularly to the skin, and deeply, so as to take up a good thickness of the tissues. It is then carried under the floor of the wound, and brought out under the skin on the other side at the same distance from the edge. The ends of each thread are then drawn together and tied in a knot, care being taken to produce an exact approximation of both the deep and the superficial parts. The *serre-fines* are removed as the suture of the wound proceeds. When all the threads are drawn tight, the junction of the edges of the wound where it might gape a little, is completed by means of pins, and the whole is covered with a pledget of lint spread with ointment. Dr. Vibert has obtained, in about thirty cases to which he has applied this plan, firstly, immediate union completed from the eighth to the tenth day, when the conditions of approximation are favourable; secondly, a partially immediate union, entirely completed from the fifteenth to the twentieth day, in instances where part of the wound has not escaped suppuration; thirdly, a more tardy, but relatively shortened union, in cases where the gaping of the edges of the wound has only allowed them to be partly approximated.

RADICAL CURE OF HYDROCELE BY ELECTRO-PUNCTURE.—Ehrhard (Betz's *Memorabilien*, Heft 8, 1874) has employed electro-puncture with permanent good effect in four cases of hydrocele. He uses the interrupted current from a small Gaiffe's apparatus. In three of the cases, the hydrocele was only of short duration, and absorption took place in from three to four days, without any reaction. The hydroceles had not been previously tapped. In the fourth case, the patient was a man aged 52, who had had hydrocele eight years, and had been tapped many times. Under the use of electro-puncture, absorption of the fluid took place in three weeks. Four months afterwards, there was no indication of a return of the malady.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 6TH, 1875.

MANSLAUGHTER BY INFECTION.

THE case of the Coventry midwife, Elizabeth Ingram, who has just been acquitted of the charge of having caused the death of Catherine Johnson, by communicating to her puerperal fever, possesses several points of interest. In Mrs. Ingram, we have a fair specimen of the English midwife, an useful, well-intentioned woman, but, as Mr. Commissioner Maule, who tried the case at the Warwick Assizes, said, "an ignorant person"; so much so, indeed, that until puerperal fever came and killed four of her patients, she frankly confessed she had never heard of such a disease. Doubtless, if these poor women had died under her hands from placenta previa, the same absence of knowledge as to the cause of death would have been admitted. Death in childbed is such a disastrous accident, that the news of it spreads with great rapidity. The coroner of Coventry heard of the deaths in Mrs. Ingram's practice, and sent a police-officer to warn her not to continue her occupation until two medical men had given her permission to do so. This was certainly a step displaying great humanity; and perhaps, in the absence of other proper machinery, it was to a considerable extent justifiable. Would it not, however, be a dangerous precedent to admit; for, were we to acknowledge that the coroner had legal right to act in this way, what might not follow? Suppose, upon hearing of the death of a patient, say from *post partum* embolism, this officer were to send a police-inspector to the medical man who attended the case, with an order to abstain from all midwifery practice until two of his medical brethren, who might be friends or foes, should give him permission, what would be the astonished practitioner's feelings? Coroners, unfortunately, are not always medical men. In this particular case, he might be a lawyer, and public opinion might report to him the embolic case as one of puerperal fever. The unfortunate individual who had attended the case would then have thrown upon him the burden of disproof; and, if he succeeded in convincing the coroner that his case was one of a non-contagious character, he would probably fail in disabusing the minds of a majority of his neighbours, who, giving themselves the benefit of the doubt, would, in a case of need, rather employ some one upon whom the puerperal taint had not been cast. It is evident, therefore, that the admission of the coroner's power to enforce prolonged quarantine upon obstetrical practitioners would be a serious mistake: and the actual exercise of such authority, were it ever granted, would most certainly prove extremely vexatious and insupportable.

But it may be fairly asked what should be done in a case such as is on record, where a medical man who attended ten labours, eight of the women dying of puerperal fever, or in a case also on record where a midwife who delivered twenty women, sixteen of whom died,—determine, in spite of fatal experience, to continue their practice. Is a medical man who recklessly, or a midwife who ignorantly, continues to attend cases of labour immediately after the occurrence of puerperal fever in his or her practice, to be allowed to proceed unchecked? In such cases as these, the coroner might rightly interfere, and, in his inquiry into the cause of death, elicit from experts the degree of responsibility incurred by the practitioner, and accord a salutary verdict in conformity with the evidence. So little doubt now exists as to the contagiousness of puerperal fever, that it is scarcely possible to believe that any medical man

would wilfully expose his patient to danger, or himself to remorse, by conducting a labour shortly after being in attendance upon a woman suffering from contagious fever. If, however, he should have the hardihood to do so, public safety demands that some legal method should exist for staying his death-dealing career.

Another point of interest in this Coventry case is, that it has aroused the attention of the *Times* newspaper. In a leading article which appeared on the 2nd instant, the insufficiency of the law for preventing the propagation of contagion is pointed out, and the fatal course now pursued is very justly attributed to ignorance. The writer says: "If sanitary legislation were for a short time to be guided by knowledge, and by considerations of public safety and economy, the conveyance of puerperal fever by midwives would be prevented as part of the application of sound general principles, and without any special enactment. If such a prospect is too remote to be waited for with resignation, it would not be difficult to find a remedy for the particular evil. Midwives are a very useful class of persons; but in too many instances they are lamentably ignorant of the duties they undertake. They ought to be placed under the control of one of the medical corporations or societies, so that they might be properly instructed and duly licensed. It would then be easy to enact that the local health authority, on the report of the coroner, or on other due cause shown, should have power to suspend the midwife's license for a stated period, until she could resume her practice without conveying to her patients the germs of fatal disease." It will be observed that the proposals here made are very much in accordance with those suggested by the Joint Committee of the British Medical Association and the Obstetrical Society of London. Every day the fact presents itself with increasing importunity, and sometimes hideous vividness, that midwives must be improved or abolished. The latter plan is undesirable and impossible; the former is practicable, urgently demanded, and, to our shame be it written, has been adopted in every European country but Great Britain.

ZYMOTIC POISON.

AN able address delivered before the Glasgow Chemists' Association, and published in the *Pharmaceutical Journal*, by Dr. John Dougall, raises anew the question of the causes of Putrefaction and of Zymotic Disease, asked, in the first instance, by Hallier; inquired into afterwards by Pasteur, Bastian, and others; and now being investigated by many physiologists and men of science. Of the two theories which have been held on the subject, Dr. Dougall forcibly advocates that supported by Bastian, that germs may appear *de novo*, and without being caused by pre-existing germs. For our own part, we are strongly inclined to agree with him. It has, indeed, for some time appeared to us a rather crude assumption that, because there are many points of agreement between, for instance, the phenomena of the growth of the yeast-plant, and the inoculation of small-pox or infection by scabiosa, that therefore the cause of the latter as of the former set of phenomena must be similar germs or spores. That is the precise point in question; and the argument from analogy, or, as we may in this case express it, the argument by Mr. Mill's "Method of Agreement", seems by no means to warrant the conclusion drawn from it. When we come to apply the same writer's "Method of Difference", we are the better able to realise the fallacy underlying the argument. Thus, the two sets of phenomena agree in many respects, but they differ in at least one important particular; namely, that in fermentation the spores of the yeast-plant are at once easy of demonstration, and their source from pre-existent germs is matter of observation; while, in the case of zymosis, either no such organisms are found at all, or, if they be, it has yet to be proved that they are introduced into the organism in that form. When this is all the proof advanced in support of the theory, it manifestly becomes a duty to suspend judgment at least till such time as further corroboration of its truth is offered us. And when Dr. Bastian tells us that organisms appear readily in organic solutions which have been boiled and otherwise treated so as to destroy any con

tained microzoa, provided only the solutions contain organic matter of a high order of complexity, the probabilities become rather strong that such organisms and their spores also are formed, not from pre-existing germs, but arise *de novo* simply from the interactions among themselves of the contained organic particles of complex composition, and unstable equilibrium.

The view which medical men take of a question like this is of the utmost possible consequence, and affects speedily the manner in which they will be disposed to view the whole subject of zymotic disease. According to the prevalent opinions, a specific disease can arise only if the specific poison or germs have by some means been taken into the organism of the person affected. If this be true, the question, how the first case of the specific disorder under consideration originated, becomes impossible, or nearly so, to answer. Besides, the argument when pushed, implies the eternal existence of the germs in question, a supposition which, of course, may be correct, at the same time that it is one whose opposite is a good deal more likely in a world characterised at all points by the constant perishing of existing organisms, and the equally constant formation of new ones. But if the other view be taken, that matter in a state of change can, when introduced into suitable conditions, as, for example, the human or other animal organism, induce a new set of changes, which we call a specific or zymotic disease, we venture to think that a good deal of obscurity and difficulty in understanding specific disorders disappear. The only addition which it is necessary to make to this theory is, that the new disorder once produced is capable of reproducing itself. And it may do this in one of two ways; either by the detachment of actual germs, formed in the supposed manner; or by particles of organic matter in a state of change, which, being introduced into a new organism, affect it by setting its particles into change or motion, and so inducing the condition now known as zymotic disease.

But the power of self-perpetuation possessed by zymotic disorders, though a very noticeable and a very interesting one, is accompanied by so many deviations and irregularities as to make it more than worth our while to pay a good deal of attention to them. For we do seem to have, in common medical experience, not unfrequent instances in which a given infection produces not itself but another, to which it is recognised to have relations. For instance, there seems to be a good deal of evidence to show that the same matter in a state of unstable equilibrium which will induce diphtheria in one individual, may induce malignant and low typed scarlatina in another; and it seems very likely indeed, that peritonitis or metritis, or some similar affection, is frequently caused by the same power in lying-in women. If this be not so, it is very difficult to account for the frequent co-existence of these disorders in time. There are other relations, as, for instance, that undoubtedly subsisting between hospital sore-throat among nurses and medical officers, and the condition called erysipelas among the inhabitants of the wards, which are very difficult of explanation on the commonly received notions, but become much more intelligible if some such view as we have enunciated be held concerning them. Nor are other instances wanting in which a given cause produces different morbid states. Most medical men, for instance, who have seen much of fever, must have seen instances such as have come under our own observation, where a whole family suffer from the same infection, yet the symptoms vary immensely in different members. We have an instance of this kind before us, in which typhoid fever in the father has run on for nearly sixty days, being characterised by diarrhoea and rose-coloured spots, while, in other members of the family, there has been neither diarrhoea nor eruption, and the duration of the disorder has been only ten or twelve days; while in yet others of the family, it has lasted twenty-one days. The source of the infection in all these cases being the same, it surely cannot be maintained that the originating germs, if such they were, are capable of producing only their own development, in any sense at all analogous to that in which, for instance, the yeast-spores produce spore-bearing penicillium, or the acorn produces the acorn-bearing oak. It is, we believe, just here that the fallacy of the prevailing views becomes apparent. Because in all the higher animals and

plants, and in a great number of the lower, which have been examined, the mode of propagation is by spores or germs; and because the penicillium, a spore-produced fungus, bears a considerable number of resemblances in its phenomena to the condition known as zymosis, it is assumed that the latter resembles it also in being propagated by spores which are in turn invested with the power, like those of penicillium, of reproducing only themselves. So long, indeed, as nothing more was intended by this than the pointing out of interesting analogies, the reasoning might pass. But surely not when it is attempted to found on mere analogy a conclusion based on the assumption of fundamental facts in the nature of zymosis—facts which cannot be received as such, until their existence has been verified. From our point of view, indeed, it appears extremely probable that germs may originate *de novo*; and we cannot help thinking that a large amount of the obscurity attaching to the subject has arisen from the extreme unwillingness which investigators have exhibited to think such a condition a possible one. To put the matter shortly; it certainly seems to us that if there be not sufficient evidence to warrant us in holding with Dr. Dougall, that "bacteria and fungi in dead matter, also the various animal and vegetable parasites of living organisms, are absolutely non-zymotic, the result, and not the cause, of the morbid conditions of their habitat", there does seem sufficient to warrant us in saying that hitherto too much attention has been paid to the cause or so-called germ, and too little, by a long way, to the habitat or nidus on which it chanced to settle. Nor would this view, we think, be found to militate against the investigation of the causes of zymotic disease, since, though the contention is that there may be an origination of specific disorder *de novo*, it is still admitted that by far the commonest source of specific disease, as we meet it, is a pre-existing case of the same kind. We shall await with considerable interest the results of the investigations now being undertaken by such men as Dr. Burdon Sanderson into this matter, feeling, as we do, that on this important question the proper attitude is one of caution and reserve, and that we shall not be in a proper position to come to a conclusion on the matter till a large mass of new evidence has been well digested and allowed its fair weight in the controversy.

HOSPITAL SATURDAY v. HOSPITAL SUNDAY.

LAST week, in commenting upon the distribution of the Hospital Saturday fund, we pointed out with surprise the high place which was assigned to the Metropolitan Free Hospital on the score of efficiency, and the relatively large sum which had been awarded to it. This gives the managers a ground for congratulation, of which they have not been slow to avail themselves. Mr. Joseph Fry writes as follows to the papers:—

"After the lengthy correspondence which you obligingly inserted on the difficulty of understanding upon what basis, if any, the insignificant sum of £78 : 3 : 1 had been awarded to this hospital by the Sunday Fund Distribution Committee out of a total collection of £29,678 : 13 : 2, and subsequently the serious charge made against this hospital of extravagant cost of management, etc., it is very gratifying to have to inform your readers that the Saturday Fund Council have thought proper to award us, out of a first year's collection of £4,521 : 15 : 10½, no less a sum than £76 : 1 : 2. It is, however, made doubly gratifying by the announcement contained in Captain Mercier's letter, which has been published, that the distribution of the Saturday Fund has been made upon the bases of 'relief', 'economy', and 'efficiency', and 'upon a plan which obviated the possibility of partiality'. A more complete vindication of this hospital from an independent source, and its claim to public support, which is now much needed, it would be difficult to adduce."

Against this is to be set the statement of the Hospital Sunday Fund in their last report, to which Mr. Fry alludes. "From the information furnished by the authorities of the Metropolitan Free Hospital, it appeared that the cost of management was rather more than 34½ per cent. of the amount spent upon the maintenance of the patients. Now, the instruction of the Council was to the effect 'that no institution be permitted to participate in the distribution of the fund if the Committee of Distribution find the cost of its management exceed a reasonable

percentage of the whole current expenditure'. If the Committee had acted strictly upon this instruction, they would have made no award at all to the Metropolitan Free Hospital. . . . They express their regret that their invitations to the Committee of this hospital to send a deputation to attend a conference at the Mansion House should have been twice declined."

We confess that we have more confidence in the manner in which the awards of the Hospital Sunday Fund have been distributed than we have in the absurd system of marks adopted by the Hospital Saturday Fund; and the candour with which the Mansion House Committee twice invited the managers of the Metropolitan Free Hospital to discuss the matter with them, contrasts most favourably with the way in which the latter shrank from any such conference. They avoided an interview with those who were best able to enter into details, and who were perfectly willing to alter the award, if good reason for so doing could be assigned, whilst they indignantly appealed to the public in the newspapers against the injustice of their decision.

But not only have the Committee of the Metropolitan Free Hospital made the distribution of the Hospital Saturday Fund an occasion for venting their displeasure against the Hospital Sunday Fund, but they have recently issued a pamphlet, addressed to their own Governors, consisting of an indignant "refutation" (as they consider) "of the injurious charges against this hospital contained in the report of the Hospital Sunday Fund". It appears to us, however, to be no refutation at all. The assertion of the Hospital Sunday Fund was that "the cost of management was rather more than 34¾ per cent. of the amount spent upon the maintenance of the patients". The whole question seems to turn upon the words *management* and *maintenance*. The Mansion House Report, in a foot-note, explains that maintenance includes the sums paid for provisions, wines, drugs, and surgical appliances, domestic expenses, salaries, wages, etc. (except as below), rent, taxes, etc., repairs, furniture, and miscellaneous charges; while management includes salaries paid to secretary, office clerks and collector, including poundage and other payments, printing, advertising, stationery, postage and law charges, and incidental expenses. It would appear, then, that it was under this last head—management—that the extraordinary amount of 34¾ per cent. of the whole income of the hospital was expended. Of this fact, the pamphlet offers no explanation whatever. It gives an abundance of statistics, and compares itself, with great self-complacency, with eight other hospitals, but it carefully abstains from giving us any insight into the relative cost of maintenance and management, as those terms were most properly explained and insisted upon by the Hospital Sunday Fund. The sums which are set down for each hospital as the total cost of its in-patients include in every case both maintenance and management. In the other hospitals, the Mansion House Committee considered that due economy was shown in the management; but, in the case of the Metropolitan Free, they deemed the proportion so extravagant that, if they had acted according to the letter of their instructions, they would have made no award to it whatsoever. For the Metropolitan Free Hospital to give its in-patient expenses in a lump is no answer to the allegations of the Mansion House Committee.

THE *Times* obituary column of the 4th instant, announces the death of a young man from misadventure in taking an overdose of chloral. The constant recurrence of deaths from this cause ought to teach non-professionals caution in the use of narcotics.

TRICHINÆ, according to a Nordhausen paper, have recently been found, on microscopic examination, for the first time, in the flesh of a wild boar. Hitherto, it has been believed that these parasites infected the domestic pig alone.

FROM an official report prepared by the Prussian Minister of Instruction, it appears that there are in Prussia 1,050 blind children between the ages of eight and sixteen (both inclusive); and 6,521 deaf and dumb of the same age. Of the latter, the province of Prussia furnishes

2,076; while in Brandenburg, the population of which is scarcely less than that of Prussia proper, the number of deaf and dumb children is only 472.

THE BRITISH MUSEUM.

WE learn, with great pleasure, that speedy redress is to follow the representations which it was our duty to make recently, concerning the unhealthy atmosphere of the apartment in which the junior assistants in the library of the British Museum were confined, and from the effect of which the health of the late Mr. Warren gave way, and that of others has been suffering. The "tank" is condemned, and the assistants, we understand, are to be removed to healthy quarters. The course which the trustees have taken in personally investigating the matters of complaint, and redressing them by their direct action, is worthy of all praise, and is of happy augury. We shall not be doing more than justice, if we add that public thanks are especially due to Dr. Hooker for the course which he has taken in the matter.

THE INQUEST ON SIR CHARLES LYELL.

THE new coroner for Central Middlesex has incurred very severe blame for insisting on holding an inquest on the late Sir Charles Lyell, under circumstances which, it is alleged, rendered any inquest unnecessary. It ought, however, we think, to be noted in mitigation of the very severe judgments which have been publicly pronounced, that the death was not remotely connected with a serious injury, which does not appear to have been mentioned in the medical certificate of the cause of death, and that the unfortunate circumstances which have caused most comment were brought about by the leaden coffin being soldered down after the notice of the inquest had been served by the authorised officer. This is obviously an undesirable method of frustrating the coroner's interference. It must be remembered, also, that it is the coroner's duty to inquire into cases of death, violent or accidental, and that more public injury is likely to accrue from defect than from excess of zeal in the performance of those duties. We cannot help thinking, that it was much to be regretted that any opposition was made to the holding of the inquest. The prejudice against such an inquiry is wide-spread, but it is opposed to the public interest.

SANITARY AREAS.

THERE is, we believe, reason to expect that Mr. Selater-Booth's forthcoming Public Health Bill will now include a more important revision of the clauses of the Public Health Act of 1872, relating to consolidation of sanitary areas for authorities than might be gathered from his recent speech at the first reading. In this respect, the failure of that measure, which was amply foretold by the British Medical and Social Science Associations, has been so conspicuous that an amendment is urgently called for.

ADULTERATION MADE EASY.

THE more the Government Bill for amending the Adulteration Act is considered, the deeper the condemnation which it is felt to deserve. It elevates ignorance into a fine art, and intimates to the facile retailer that 'tis indeed the height of folly to be wise. If he will only henceforth plead ignorance, his servants or his purveyor may skim the milk or add water to it, may mix sand with sugar, alum with bread, lard with cocoa, flour with mustard, and chicory with coffee. The retailer need only plead that he had his back conveniently turned, that he sold it as he bought it, that he really did not do it "knowingly"; or, if that should openly fail, then he may plead that "mixture" is the custom of the trade, and adulteration the badge of all his tribe. He may sell a mixture as cocoa, another mixture as mustard, a third as pepper, a fourth as ground coffee; and, if he have only the very small artlessness to plead that it is the usage of trade, that he sells as he buys, or that he "knows" nothing beyond that, he may safely adulterate under the shade of his own counter, and in the secrecy of his back parlour. The enactment is equally calculated to favour tampering with drugs; and it ought unquestionably to be entitled an Act to protect from all penalties the adultera-

tion and deterioration of food, drink, and drugs. It must go beyond the wildest hopes of the gentlemen who were suffering from the very mild prohibitions of the Adulteration Act, and who procured the appointment of a select committee to hear their prayers.

SMALL-POX AND REVACCINATION.

A REPORT of the Small-pox Hospital, Blackwell's Island, in the *New York Medical Journal*, of February 1875, states that one of the most interesting facts brought out by the hospital cases is, the value of vaccination as a preventive. The vaccination of childhood is of no value, unless repeated at intervals of three years. This is proved by the fact that all, or nearly all, of the cases have good pock-marks; though, at the same time, it is true that the cicatrix does not prove the validity of the vaccination. Again, the fact of having had the disease does not preclude the possibility of again taking it, and should not preclude the necessity of revaccination. It not unfrequently happens that a patient enters who is strongly pitted; and a patient in the Jersey City Charity Hospital had the disease three times. The strongest argument in favour of frequent revaccination is that, of all the cases under observation, not one can be found who has been successfully revaccinated within four years; and there are only a few even who were vaccinated four years ago. But while this is considered a rule, it is not without its exception, the case is mentioned of a child who was vaccinated successfully at a dispensary on the east side, and in a year from that time took small-pox. Another interesting fact occasionally noticed in hospital is, that small-pox and cow-pox run their course together in the same patient, each entirely uninfluenced by the presence of the other.

BIRMINGHAM WATER-SUPPLY.

AMONG other matters more or less intimately connected with the sanitary condition of Birmingham, which have recently attracted considerable attention, it is satisfactory to find that the quality of its water-supply is not being lost sight of. Month after month, Dr. Alfred Hill, the medical officer of the borough, has reported that the amount of "previous sewage contamination" in the water supplied to the town, either "continues very high", or is "higher than in the previous month". One of the results of the recent Conference has been the organisation, in Birmingham, of a course of lectures on sanitary subjects, and Dr. Alfred Hill recently delivered one of the series, entitled "Good Water". In the course of the lecture, by the aid of a number of interesting chemical experiments, he exposed the polluted state of the water which was being drunk, and then proceeded to point out the danger of drinking impure water, and its especial tendency to disseminate cholera, diarrhoea, and typhoid fever. Such efforts to educate the public in the real importance of these matters, will no doubt assist in strengthening the hands of the Town Council in its efforts to improve the sanitary condition of Birmingham, whether in the improvement of its water-supply or any other direction.

ACTION OF SALICYLIC ACID IN BACTERIA.

DR. LUDWIG LETZERTZ has lately tested the effect of salicylic acid on bacteria and micrococci, by placing under the microscope portions of fluid containing these organisms in abundance, and allowing solutions of salicylic acid to come into contact with them. He used solutions of four degrees of strength; viz., one part of salicylic acid and one of spirit, in 120, 90, 60, and 40 parts of water. The first two (the weaker solutions) arrested the movements of the bacteria gradually; while, with the two stronger solutions, the arrest of movement was instantaneous. He has used salicylic acid locally and internally in two cases of diphtheria, he thinks with good effect; but he observes that more extensive observations are necessary in order to determine its value in this disease.

THE ABOLITION OF VIVISECTION.

THE following advertisement appeared in *The Times* a short time ago. "Society for the Abolition of Vivisection, or putting animals to death by torture, under any pretext whatever. The object of the Society

is a law for the total suppression of vivisection. To call on the legislature for less would be to admit the principle (and thereby perpetuate the enormity) that man is justified in selfishly inflicting agony on the innocent. The opponents of the Slave Trade agitated, not for restriction, but abolition. The wrongs perpetrated by man on animals are even more dire than those inflicted by him on his own species. Persons desirous of joining the Association can communicate with George R. Jesse, Esq., Henbury, Macclesfield, Cheshire."

ROYAL ALBERT HOSPITAL, DEVONPORT.

WE are glad to learn that the provident out-patient department of this hospital continues to make steady progress. The Report just issued says: "The Provident Dispensary is still worked in a very satisfactory manner. The annual subscriptions are increasing, and the fines for the non-payment of subscriptions are diminishing." In 1873, the payments of members amounted to £432 11s. 10d., while last year they had risen to £491 16s. In 1873, £147 13s. 6d. were divided among the four medical officers, while last year £256 14s. were similarly distributed. The following extract from the Report for 1873 expresses the opinion of the Committee as to the general working of the system, and the experience of another year has only served to strengthen them in it. "The Committee are more than ever confirmed in their view of the advantages arising from the institution; there can be no doubt whatever that its principal merit is to establish and increase habits of providence and forethought among the working classes, but great relief is also afforded to the suffering poor. Several cases have been admitted as in-patients of the hospital on the recommendation of the junior surgeons—not as a matter of charity, but as a part of the relief purchased by their original subscriptions. In this way the members have the benefit of the superior appliances of the hospital, and the latter is a gainer as a medical school by being supplied with a succession of important and selected cases."

NATIONAL HEALTH ADMINISTRATION.

THE following lines from the pen of Sir Arthur Helps deserve careful consideration. They confirm an opinion which we have long since advocated, and come from one of the ablest and most thoughtful of our public servants.

"I distrust the agglomeration of offices and functions which has been so frequently effected in modern times. It seems to me that the health of the nation is a subject sufficiently large in itself to require a separate branch of administration, with a minister at the head of it; and that it has been unwise to add this branch to the Presidency of the Poor-law Board. The functions seem to be essentially different. In the one case judicious restraint appears to be the principal function; in the other, judicious enlargement and development of action. I should imagine that it would rarely happen that any one man would possess the requisite qualifications for filling, as a minister, both these high posts of president of the Poor-law Board, and president of my imaginary Board of Health. But, indeed, the allotment of official work is, at present, very ill-managed throughout most of the departments of the State."

HYDROPHOBIA IN DENMARK.

A CORRESPONDENT of the *Pall Mall Gazette*, writing from Copenhagen, directs attention to the fact that rabies exists to an alarming degree in nearly all the towns of Jutland. As a proof of the feeling in Copenhagen on this subject, he mentions that the press is insisting upon the necessity that the Minister of the Interior should by a short bill make it an offence for any one to bring a dog from Jutland to any of the islands, thus trying to limit this terrible scourge to the Peninsula, whither it has been brought, to all appearances, from Germany, and especially Berlin, where rabies existed a short time ago to an alarming extent. There is hardly a day when the Danish papers do not cite one or more cases; and several people have already died from this terrible disease.

THE WORDING OF ACTS OF PARLIAMENT.

MR. FORSYTH, in a recent speech, called attention to the vague manner and involved language in which Acts of Parliament were drawn up. As an instance, he alluded to the Public Health Act of 1872. Of late years, he said, there had been a constant habit of making enactments, not by plain and distinct words expressed on the face of the Act, but by

referring to other Acts passed in previous years, and by incorporating a portion of preceding Acts, so that it was necessary to go back to those Acts to ascertain what, in fact, the Legislature meant. But that was a hopeless task; one became involved in a perfect chaos. There was also this habit—an Act was repealed, not bodily, but only a section or a portion of a section; and annexed to the new Act was a schedule which stated that so much of former Acts as were not repealed remained in force, and one had to go back from Act to Act. Even to a lawyer the task was almost hopeless. The Public Health Act, passed in 1872, was for the purpose, among other things, of establishing a new Sanitary Authority, and laid down the powers and duties of that authority. How was that done? By referring to five distinct classes of Acts of Parliament, one class containing five Acts, and the whole making a total of sixteen Acts of Parliament, from which the rights, the duties, and the obligations of the new Sanitary Authority had to be ascertained.

NECROPSIES IN PUBLIC INSTITUTIONS.

A FEW weeks ago, it became our duty to comment rather severely upon the action taken by the Board of Guardians of the Portsea Island Union Workhouse, in respect of *post mortem* examinations made by the medical officer. A somewhat similar affair has lately occurred at the Hackney Workhouse, where the House Committee have been called upon to investigate "alleged improprieties on the part of the medical officer of the workhouse, in the matter of making an unnecessary number of *post mortem* examinations". The committee ascertained that this officer had made nineteen *post mortem* examinations in all during the time that he had held office there, and that of these, one had been ordered by the coroner, and eighteen had been made at the request of the friends of the deceased, and that the committee decided to admonish the medical officer, and to frame a rule that in future no deceased inmate should be "dissected", excepting by order of the coroner or the guardians, or by a written request of the friends of the deceased. We fail to see what change this rule was intended to effect. Possibly it was framed simply to calm the instigator of the proceedings, who "considered that it was incumbent on the board to express its decided disapproval of the conduct of the young officer who had dissected the dead", and who, to the last, prevaricated that the "dissections" alluded to had not been made at the request of the friends, though he finally admitted that the friends had given permission. It leaves things, however, in exactly the same position as they were before. The medical officer had invariably obtained the consent of the friends, and it would not be difficult to have that consent or request in writing. We have no great complaint to make, provided the matter rests here. We think it desirable that, whenever an opportunity occurs of making a necropsy, the opportunity should not be neglected, but we would not willingly hurt the feelings of relatives who, from prejudice of whatever kind, have objection to necropsies. We must, however, assert that the report of the House Committee proved that the medical officer had been careful not to make any examination of the deceased without the sanction of those who had the right to give it. And if, by so doing, he broke no law of the institution with which he was connected, to admonish him was a deliberate and gratuitous insult.

TRIAL OF A MIDWIFE FOR MANSLAUGHTER.

AT Warwick, on February 27th, before Mr. Maule, Q.C., Commissioner, Elizabeth Ingram was charged with manslaughter. Mr. Edwin Bennett appeared for the prosecution; and Mr. Buszard defended the prisoner. The prisoner is a midwife practising in Coventry; and, during the month of December 1874, she attended seven women, five of whom had puerperal fever, and two escaped. Four of the women died. The prisoner was charged with having, by gross negligence, caused the death of Catherine Johnson, upon January 8th, 1874. On December 18th, a police-sergeant saw the prisoner, and told her he was directed by the Coroner to warn her not to practise for two months, in consequence of the death of a woman whom she attended. The prisoner replied that a medical man had promised to see to her work for her, and had told

her she might go into the patients' rooms, but was not to take any part in the delivery. Dr. John Brown of Coventry had told the prisoner that her patient, a Mrs. Williams, had died from puerperal fever, and that the prisoner ought not to attend other patients for at least two months, for they would probably all die, as the fever was so contagious. In cross-examination, Dr. Brown said he had himself abstained from attending other cases for six or seven weeks after attending a case of puerperal fever. He and Dr. Dewes explained at length the nature of puerperal fever; and, from their evidence, it would appear that there are three forms of the fever. The first is that which appears sporadically, or as an original disease; the second (this case) is one which is eminently contagious and deadly; and the third form is one in which there are no inflammatory symptoms and no contagion, but which is of a typhoid character. A midwife would not know from which class the patient suffered. This fever has no doubt been epidemic lately, and such epidemic form may arise from the peculiar condition of the atmosphere, as in the case of other fevers. A medical man cannot tell in any particular case whether or not it arose originally or from contagion. The mother of the deceased, acting on the advice of the prisoner, sent the husband to fetch Dr. Middleship, who came about two o'clock in the day and said that he would be wanted again about six o'clock. The husband went for him about that time, and urged him to go directly. According to the husband's account, Dr. Middleship said: "You go back and tell her (the prisoner) from me she had better go on with the case." The prisoner had not touched the patient; but, after receiving this message, she delivered the woman on December 24th, and she died on January 8th, of puerperal fever. Dr. Middleship stated that he attended the deceased four or five hours before confinement. The prisoner was in the room. On December 18th, he had a conversation with the prisoner about attending her cases. He said he would attend to the cases for her. She told him she had been stopped from attending by the inspector and by the coroner, and was not to attend any more for two months. He had attended a Mrs. Chapman six days. She was attended by the prisoner, and died of puerperal fever. He had attended her two or three days after her confinement. He recollected the deceased's husband coming for him at six o'clock. He said to him: "Go and tell her that I am going to a case of my own, and if she should get any worse to let me know; and, if I have returned from my own case, I will come directly." He made no suggestion that any other medical man should be called in. He did not go to the house of the deceased that evening. He believed the prisoner said that her patients had died of childbed fever. His lordship, addressing the learned counsel for the prosecution, said: Can you support this charge? Here is this woman, who is an ignorant person, and cannot know of herself whether the form of complaint she has been dealing with is contagious or not, who receives a warning from the police and the coroner, who communicates with a doctor and states the reason why she has been warned, and is told she may be present in the room. Then, when the labour comes on, the doctor leaves her to herself, and the husband delivers a message to her to the effect that the doctor, who knows all the circumstances, has given her authority to act in the matter. The learned counsel for the prosecution stated that, from the depositions taken in the case, he had thought that the charge could not be substantiated against the prisoner at the bar. His lordship then directed the jury to find a verdict of not guilty.

RECENT URBAN MORTALITY.

DURING last week, 5,449 births and 4,454 deaths were registered in London and twenty other large towns of the United Kingdom. The rate of mortality was 30. The rate was 26 in Edinburgh, 34 in Glasgow, and 29 in Dublin. Portsmouth had the lowest rate (21) of eighteen large English towns. In Bristol, Leicester, and Norwich, the rate was 31; in Wolverhampton, Liverpool, and Birmingham, it was 33; in Salford, 35; Nottingham, 38; Manchester, 39; and Oldham, 41. The zymotic rate in these eighteen towns was 3.1; it was 5.6 in Birmingham, and 5.8 in Hull. Whooping-cough caused 15 deaths in

Birmingham, and scarlet fever again showed fatal prevalence in Bradford and Hull. In London, 2,348 births and 1,854 deaths were registered. The births were 148 below, the deaths 173 above, the average. The death-rate rose to 28. The deaths referred to the seven principal zymotic diseases were 176, being 78 below the average. To whooping-cough, 71 deaths were referred; which number was, however, slightly below the average. The mortality from this disease has increased rapidly during the past few weeks. Under the influence of the continued low temperature, 576 deaths were referred to diseases of the respiratory organs, which exceeded the corrected average weekly number by 191. In outer London, the death-rate from all causes and from the principal zymotic diseases was 22.3 and 1.6 respectively, against 28.1 and 2.7 in inner London. Typhoid fever is said to be prevalent in Moor Cottages, High Street, Ilford. At Greenwich, the mean reading of the barometer during the week was 29.54 inches. The mean temperature was 33.5 deg., or 5.9 deg below the average. The general direction of the wind was E.N.E. Rain or melted snow was measured on Wednesday and Thursday to the amount of .20 of an inch.

TRIAL OF A SURGEON FOR MANSLAUGHTER.

THE following is a condensed report from the daily papers of the trial of a surgeon at Warwick Assizes, for causing the death of a woman whom he attended in her confinement, by cutting away many feet of intestine, which protruded through a rent in the vagina. Strenuous endeavours were made to save the accused, Dr. Barnes making a strong effort to put forward all the palliating circumstances. Unfortunately, the weight of evidence could not be resisted; the sentence of the court was mitigated by the facts that the poor woman would, in any case, have died. On March 13th, before Lord Coleridge, Mr. Edwin Peacock, a surgeon, was indicted for the manslaughter of Ann Woodward, on June 19th last—under very painful circumstances, to which we have previously referred.—Mr. Fitzjames Stephen, Q.C., and Mr. Buszard appeared for the prosecution; Mr. Digby Seymour, Q.C., and Mr. Dugdale for the defendant.—Last June the prisoner attended Ann Woodward, wife of a labourer at Chilvers Coton, during her confinement. An internal rupture was caused, which resulted in the protrusion of fifteen feet of intestines, which the prisoner cut away. Medical witnesses were called on both sides, but even those who appeared for the defence said that personally they would not have severed the intestines. The coroner's jury acquitted the prisoner of blame, but the present prosecution was ordered by the Attorney-General.—Mr. Fitzjames Stephen, Q.C., in the course of the opening of the case for the prosecution, stated that this case had been prosecuted under the direction of the Treasury, and the details of it would give as much pain and disgust to the jury as they would give him to state. The prisoner, who is a surgeon practising at Chilvers Coton, had attended the deceased Ann Woodward, during her confinement, and the question for the jury to consider was whether his conduct on that occasion amounted to manslaughter. It was the law that, if a person undertakes a difficult and delicate task, he is bound to bring to the execution of that task the required knowledge, skill, and care. If he fail in any one of these, he is liable to a charge of manslaughter if death supervene.—Though the medical evidence differed on some points, it agreed in affirming the impossibility of the patient's life being saved after the operation performed by Mr. Peacock, who cut away and removed fifteen feet of the intestines. After an hour's deliberation, the jury returned a verdict of guilty, with a strong recommendation to mercy. Lord Coleridge said, he entirely concurred with the finding, but, as there was an absence of all aggravating circumstances, the sentence would be six months' imprisonment without hard labour.

THE FOOTBALL CHALLENGE CUP.

ON Wednesday last, notwithstanding the bitter coldness of the weather, some four hundred spectators assembled at the Oval, Kennington, to witness the decision of the final tie for this prize. The match lay

between the Guy's and St. George's Clubs, and excited much interest amongst the partisans of those two medical schools. The game was admirably contested throughout. The St. George's men scored two touches down during the first half of the match, when the Guy's men were kicking against the wind; but, after the change of ends, the advantage rested with the latter team. Gray ricked a goal from a run in by Mutch, and their adversaries were once forced to touch down. In the end, the Cup went to Guy's; the Borough men having scored a goal and a touch down to two touches down. Mr. W. Pinching was captain of the Guy's team; and Mr. W. E. Collins acted in a similar capacity on the St. George's side.

DISCUSSION AT THE PATHOLOGICAL SOCIETY.

THE Council of the Pathological Society have arranged that a discussion shall be opened, by Dr. Charlton Bastian, F.R.S., at the meeting of April 6th, on the Germ-Theory of Disease: being a Discussion of the Relation of Bacteria and allied Organisms to Virulent Inflammations and Specific Contagious Fevers. It is expected that Dr. Burdon Sanderson, whose lectures on a part of this subject are now appearing in our columns, will take part in the discussion; and it is hoped that, besides the members of the Society interested in this important subject, Professor Lister of Edinburgh, and it may be Professor Billroth of Vienna, will find opportunity of being present and taking part in the debate.

SCOTLAND.

LEITH HOSPITAL.

AT the annual meeting of the subscribers to the Leith Hospital, it was reported that the ordinary revenue of the institution, during 1874, had been £1,779, and the expenditure £1,641. Upwards of £8,100 had been, up to the close of the year, expended on the new buildings. These being now ready for the reception of patients, the directors were authorised to make arrangements for their formal opening.

DRAINAGE OF THE NEW INFIRMARY, EDINBURGH.

THE drainage of the New Infirmary continues to occupy a prominent place as an important public question, and has been made the subject of several reports and counter-reports on the part of the Committee of Managers on the one hand, and the Town Council on the other. The former party consider that the ratepayers of the St. Leonard's district "have fallen into error in representing the sewage of the New Infirmary as peculiarly noxious and charged with infection, inasmuch as the number of cases of the most infectious diseases, such as small-pox and scarlatina, is always very limited, and those of common fevers, which are much less virulently infectious, rarely exceed thirty and cannot surpass fifty". They further point out that it had never up to the present time been suspected that any spread of infectious diseases had been caused by drainage communication at times when epidemics were raging in any of the public institutions in the city, and that the proposed ventilation of the drain seemed perfect, as the air from all the hospital drains is to be drawn through a furnace kept burning for other hospital purposes. The Town Council Committee, on the other hand, believe that, on the evidence before them that the sewage is specifically infectious, it would be unreasonable to give it a passage through the main sewer which, to be rendered safe, would require the thorough trapping and entire reconstruction of all the collateral drains, and the rearrangement of a very large number of the sink and closet arrangements over the whole drainage area. They also relied on the opinion of Mr. Haywood and Mr. Austen of London, that the system of ventilating sewers by furnaces was likely to prove a failure. At a special meeting of the Town Council, it was agreed that the ordinary sewage of the infirmary should be allowed to enter the St. Leonard's drain, while that from the infectious wards should be disinfected and disposed of as might be found most convenient. The matter was from them adjourned, that an arrangement to this effect might be made with the

infirmary authorities. The infirmary managers accepted the offer of the Town Council, with the promise that the sewage from the fever-house shall be disinfected to the satisfaction of the Town Council before it is allowed to enter the St. Leonard's sewer. The matter will probably be settled on this basis.

ROYAL EDINBURGH ASYLUM FOR THE INSANE.

At the annual meeting of the Corporation of the Royal Edinburgh Asylum for the Insane, Dr. Clouston, the medical superintendent, read a report, from which it appeared that the number of patients admitted to the asylum during the past year had been greater by 14 per cent. than the average for the previous ten years, and that increase had taken place equally in the private and rate-supported class of patients. Under the heading "Melancholia", there were 70 per cent. more cases admitted last year than the average number in that class for the previous ten years.

HOSPITAL FOR INCURABLES IN EDINBURGH.

THE temporary hospital for incurables is now open, and is under the professional care of Dr. J. Bell as surgeon, and Dr. G. W. Balfour as physician. The wards are comfortable and convenient, and will contain, at present, accommodation for about twenty persons. The rules as to admission are stringent, and the committee of management desire to take in, as far as possible, only the most urgent cases, in the face of the limited number of beds. The following is an abstract of the principal rules. Patients applying for admission must procure medical evidence that they labour under incurable disease of such a kind as requires nursing and care which cannot be provided at their own homes. Such cases as seem fitted for general infirmary treatment will not be received, without a certificate from a medical officer of such institution of unfitness for further treatment there. A preference is to be always given to those who apparently have not long to live, especially such as suffer from aneurism, cardiac, cerebral, or carcinomatous diseases in their advanced stages. No one subject to mental disease is to be admitted; and the phthisical only under peculiar circumstances. The claims of those desiring admission are to be sent to the Secretary, and are, together with the opinion of the medical officers on the case, to be laid before the acting committee, who have absolute power of admission or rejection, unless the medical officers unanimously object to a case, when it shall not be admitted. Judging from the urgent want of such an institution in this part of Scotland, the home will soon be overflowing with applicants.

THE UNIVERSITIES AND FEMALE GRADUATES.

At a meeting of the University court, held last week, it was unanimously resolved to petition Parliament against the Bill for removing doubts as to the powers of the Universities of Scotland to receive women as students and admit them to degrees, from several reasons: 1. Because all doubts have now been removed by the decision of the Court of Session, and, consequently, the admission of women would be inconsistent with their charters. 2. Then, in the face of so much difference of opinion as has been expressed in the matter, and the questions themselves being serious, no legislation should take place until the whole subject had been inquired into by a Royal commission or otherwise. The Bill has since been rejected.

ROYAL SOCIETY OF EDINBURGH.

THE Council of the Royal Society of Edinburgh have awarded the Makkdougall Brisbane prize for the biennial period, 1872-74, to Professor Lister, for his paper on the Germ Theory of Putrefaction and other Fermentative Changes, which was communicated to the Society on April 7th, 1873.

THE CHAIR OF NATURAL HISTORY AT ST. ANDREWS.

It is announced, that the Chair of Natural History in the University of St. Andrews, vacant by the death of the late Dr. W. Macdonald, has been offered to and accepted by Dr. Alleyne Nicholson, who, a few months ago, was elected to a similar Chair in the College of Phy-

sical Science at Newcastle-on-Tyne. Dr. Nicholson was, we understand, in no way a candidate for this appointment, which was offered to him by the Marquis of Ailsa, with the cordial approval of the University authorities.

IRELAND.

At a meeting of the Governors of Simpson's Hospital, Dublin, held on Monday, the 22nd ult., Dr. H. Kennedy was elected a physician to that institution.

MR. WILLIAM COLLES, ex-President of the Royal College of Surgeons in Ireland, Surgeon to Steevens's Hospital, has been elected to the Professorship of Surgery in the University of Dublin.

At a late meeting of the Council of the Royal College of Surgeons, a resolution was passed expressive of their regret at the death of the distinguished surgeon Mr. Robert Adams, lately a member of their body, and of sympathy with his family in their bereavement.

THE SUNDAY CLOSING MOVEMENT.

A DEPUTATION, consisting of many of the most influential citizens of Dublin, waited on the Lord Lieutenant on Saturday, with a view of urging upon His Grace the importance of supporting the Bill for Closing Public-houses in Ireland on Sundays. His Grace, while seeming to approve of the movement, of course only promised the measure due consideration. We are much afraid that the cause of temperance has been much injured in this, as in other similar movements, by the injudicious zeal of teetotalism and its supporters.

DUBLIN MAIN DRAINAGE.

IN consequence of the information elicited from the Government by the questions of Sir A. Guinness and Mr. Hankey in the House of Commons, it is reported that the Dublin Corporation will make an attempt to carry out the main drainage of the city with such moneys as they are able to obtain. As the Corporation can only legally carry out the scheme of 1871, and as that scheme will cost (if efficiently carried out) at least a million of money, it is seriously proposed by the municipal authorities to reduce the cost by substitution of rubble masonry, and other imperfect forms of work, for that originally proposed. Such a proceeding will ultimately cost the ratepayers a great deal more money in repairs and reconstructions than could possibly be expended on any efficient, though costly, scheme. We hear that a meeting of the ratepayers will be summoned in a few days, to consider what steps should be taken in the present crisis. A Bill has been prepared, to be submitted to the meeting, which would have the effect of taking the matter out of the hands of the Corporation, and entrusting it to a newly constituted body, somewhat similar to the Metropolitan Board of Works.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE annual meeting of this Society was held on Monday, March 1st, at 8 P.M.: the President, CHARLES J. B. WILLIAMS, M.D., F.R.S., in the Chair.

Dr. Samuel Gee and Mr. Fairlie Clarke were appointed Scrutineers of the Ballot for the new officers and council.

The abstract of the income and expenditure of the year 1874 was read.

The *Report of the President and Council* was read. It gave an account of the present state of the Society as to the number of its Fellows and the condition of its finances. The total number of Fellows was 654—the same as last year. The deaths had not been so numerous as in the previous year; they included two honorary Fellows (Jean Cruveilhier and Sir Charles Lyell), eight resident and five non-resident Fellows. The number of new elections to the Fellowship had been twenty-one. The ordinary income, £1363 15s. 7d., was slightly, and the expenditure, £1174 4s. 2d., considerably below, that of 1873; the latter decrease being chiefly in the cost of the library and *Transactions*. The report referred to the funded property of the Society, and to the state of the investment for the Marshall Hall Fund, and also congratulated the Society on the success of the second *conversazione* held last

June. The library had been increased this year by purchase and donation to the extent of nearly 500 works.

The adoption of the report was moved by Mr. GEORGE POLLOCK, seconded by Mr. OLIVER CHALK, and carried unanimously.

President's Address.—The PRESIDENT addressed the meeting. After congratulating the Society on its even prosperity, with a deduction on account of the scanty attendance of the Fellows at its meetings, and, on the other hand, a creditable reference to the great success of the biennial *conferences*, the President proceeded to give brief biographic notices of fifteen Fellows deceased in the past year; acknowledging his obligations to the medical journals, from which much information was derived. Professor Cruveilhier of Paris, Foreign Honorary Fellow, by his illustrations of pathological anatomy, had done more for that study than any other author during the last half-century. Sir Charles Lyell, honorary Fellow, was also foremost, not only as an author in his department (geology), but likewise as one of those who have done most to place geology on a scientific foundation. The President also referred to the death of Surgeon-Major John Wyatt, C.B.; Richard W. Tamplin, F.R.C.S.; John Burford Carlill, M.D.; Thomas Ballard, M.D.; Edward W. Duffin, M.D.; Richard T. Tracy, M.D., of Melbourne, Australia; James Dawson, F.R.C.S., who began to practise in Liverpool nearly seventy years ago; was concerned in the famous trial of Mr. Angus for the murder of Miss Burns in 1808, and, retiring twelve years ago to a large castle in Windermere, attained the age of 96 years—a prosperity and longevity rare in the medical profession; James H. Puckford, M.D., of Brighton, who attended especially to diseases of the eye; George Ford Copeland, M.R.C.S., of Cheltenham; Archibald Douglas, M.D.; and Alexander Halley, M.D. (Biographical sketches of several of these gentlemen have appeared in the JOURNAL.) The notices of Dr. Anstie and Sir Ranald Martin were taken last. The energies and abilities of Dr. Anstie did not display themselves until he reached man's estate. The innovations in the practice of medicine introduced by Dr. Todd aroused his interest; his attention was directed especially to the nervous system and its maladies. The benevolence of his disposition directed his taste for measures of reform towards the relief of the helpless and the mitigation of distress. The precocious exercise of a spirit of criticism gave a somewhat censorious bias to his mind, and a tendency to distrust and disparage the views and practices of the past. Yet he was no mere dogmatist, but also a diligent worker; and, although his labours were unremunerative to himself, they were beneficial to others, and would have laid the foundation of his future success, had he lived to build on it. Sir Ranald Martin, throughout his long and busy life, both in India and after his return to England, was quite as much occupied in honorary and gratuitous employment as in making provision for his large family; but, though his numerous and eminent services were acknowledged by honorary distinctions, there was little substantial return for the devotion of nearly sixty years of his life to unceasing and anxious toil. Merchants, planters, and civil officials of high rank, return from India with large fortunes after much less labour and shorter terms; but the most distinguished military medical officer, when obliged by ill-health to return after twenty-three years of active service, finds himself obliged to resume practice for thirty-four years more, without any enjoyment of that *otium cum dignitate* to which he was so fully entitled. Yet his services, far beyond those of routine, included a work of sanitary reform initiated in India, and carried on by himself and others in England, the effect of which has been to preserve many thousands of lives, and to save millions of money. The honour of having been an instrument in this noble work was his only earthly reward.

"Thus do the lives of Anstie and Martin reflect honour on their profession by their noble and unselfish exertions in the cause of humanity. Nor are their histories singular; nay, do they not represent the general character of the lives of medical men who find themselves called on, and refuse not, to toil night and day, often sacrificing their health, and sometimes their lives, for the relief of suffering, without, or with very inadequate, remuneration? Doubtless, it is a noble and a godlike work, and assuredly they have their reward; but this comes, not from the gratitude of the public, or from the appreciation of their services by the upper ranks of society, because unfortunately the numbers and needs of medical men are commonly so great, that some are ready to proffer their services at any or at no price; the public expects from them gratuitous work, which would not be thought of with any other profession or trade. Against such injustice, we cannot too strongly or persistently protest."

The recent proposition from the Royal Society for the Prevention of Cruelty to Animals also implied (Dr. Williams said) something like an indignity to our profession. They asked that their secretary, with two others, might be present whenever the Society had to perform experiments on living animals. The Council had replied: That, if the

Society should undertake any scientific investigations rendering such processes necessary, they would certainly decline the presence or interference of any unqualified witnesses. Those only profoundly acquainted with physiology could be competent judges of the necessity of making experiments on living animals, and of the most merciful modes of conducting them; and such experts, being also practitioners of the healing art, a great aim and constant object of which is to relieve pain and to mitigate suffering, might be implicitly trusted without the espionage and surveillance of impulsive and unqualified observers. In justification of vivisection for strictly humane and scientific ends, it had been fairly argued that, if whole hetacombs of animals are habitually and ruthlessly sacrificed, not only for food, but for luxury and for sport, and often with little or no consideration for their individual tortures, there is a much more rational and cogent plea for the use of a few for instructive investigations, which have intimate bearing on the relief of suffering humanity. Dr. Williams further argued that there is a warrant on higher grounds. The primæval command to have dominion over animals, coupled with the Christian injunction, "Heal the sick", showed that we are not merely permitted, but absolutely enjoined, to make such use of animals as science points out for the advancement of the healing art. And to whom could this "dominion" be so safely and beneficially confided as to the members of that profession of whom Ranald Martin and Francis Anstie were types?

In conclusion, the President expressed his obligations to the Council and secretaries for their aid, and to the Fellows for their kindly support, and heartily thanked them for the honour conferred on him by making him their President—an honour which he prized above all others in his professional career.

Votes of Thanks were moved, and carried by acclamation: to the President, by Mr. FAIRLIE CLARKE, seconded by Dr. ALTHAUS; and to the retiring Secretary, Dr. Symes Thompson, and the retiring Vice-Presidents and other members of Council, by Mr. JOHN BIRKETT and Dr. W. M. ORD.

Dr. C. J. B. WILLIAMS and Dr. SYMES THOMPSON returned thanks, and, after the declaration of the ballot for officers and council for the ensuing year, the meeting adjourned. (The names of the new officers and council were given at page 283 of last week's JOURNAL.)

EXAMINATION IN STATE MEDICINE.

AN examination in so much of State Medicine as is comprised in the functions of Officers of Health will be held in Cambridge in October 1875, beginning on Tuesday, October 5th. Any person whose name is on the *Medical Register* of the United Kingdom may present himself for this examination, provided he is twenty-four years of age. The examination will be in two parts.

Part I will comprise: Physics and chemistry; the principles of chemistry, and methods of analysis with especial reference to analyses (microscopical as well as chemical) of air and water; the laws of heat, and the principles of pneumatics, hydrostatics, and hydraulics, with especial reference to ventilation, water-supply, drainage, construction of dwellings, and sanitary engineering in general. Part II will comprise: Laws of the realm relating to public health; sanitary statistics; origin, propagation, pathology, and prevention of epidemic and infectious diseases; effects of overcrowding, vitiated air, impure water, and bad or insufficient food; unhealthy occupations, and the diseases to which they give rise; water-supply and disposal of sewage and refuse; nuisances injurious to health; distribution of diseases within the United Kingdom, and effects of soil, season, and climate. Candidates may present themselves for either part separately or for both together at their option. Every candidate will be required to pay a fee of four guineas before admission to each part of the examination. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a certificate testifying to his competent knowledge of what is required for the duties of an Officer of Health. All applications for admission to this examination, or for information respecting it, should be addressed to Professor Living, Cambridge.

ANIMAL VACCINATION.—Since 1872, there has existed in the *abattoirs* of Bâle a vaccine establishment, headed by a veterinary surgeon, which is used by all classes of society. Bulls are inoculated with vaccine from children, and in their turn serve as foci for vaccination. After having shaved the posterior face of the testicles of these animals, about twenty superficial incisions, from two to three *centimètres* long, are made with the instrument charged with vaccine matter. If done carefully, the operation always succeeds, and, at the end of the sixth day, it is possible to collect vaccine, which, mixed with glycerine in the tubes, preserves its properties longer than human vaccine.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL: THE JOURNAL AND MR. CHRISTOPHER HEATH.

THE Committee of Council of The British Medical Association have had their attention directed by Mr. Christopher Heath to certain articles which have appeared from time to time in the pages of their JOURNAL; and, in particular, to certain expressions made use of in an article contained in the issue of July 11th, 1874, having reference to the election at the Royal College of Surgeons.

The expressions used, and the statements made in the articles referred to, are, in the opinion of the Committee, beyond the fair limits of controversy, and might be understood to reflect upon the honour, integrity, and candour of Mr. Heath.

The Committee, under the circumstances, feel that it is due to Mr. Heath that the remarks which have given him any pain and annoyance should be withdrawn; while, at the same time, they express their sincere regret that they should have ever appeared.

YORKSHIRE BRANCH.

THE spring meeting of this Branch will be held at the Infirmary, Huddersfield, on Wednesday, March 10th, at 2.30 P.M.

The members will dine together at the George Hotel at 5 P.M. Tickets, 6s. 6d. each.

Members intending to bring forward any communication, or to join the dinner, are requested to communicate with the Secretary.

W. PROCTER, M.D., *Local Secretary*.

24, Petergate, York, February 19th, 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

THE next meeting will be held at the Crystal Palace Hotel, Upper Norwood, on Thursday, March 11th, at 4 P.M.: E. R. Ray, Esq., of Dulwich, in the Chair.

The following communications have been promised.

1. Dr. Galabin: On the Causation of Puerperal Convulsions.
2. Dr. Dalton: On a Case of Recovery from Tubercular Peritonitis, with Cerebral Symptoms.

3. Dr. Miller: On a Case of Cardiac Rheumatism.

Dinner will be served at 6 P.M.; charge, 6s., exclusive of wine.

JOHN H. GALTON, M.D., *Hon. Secretary*.

Woodside, Anerley Road, Upper Norwood, S.E., Feb. 23rd, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE next meeting will be held in the Council Room of the Midland Institute, on Thursday, March 11th, 1875. The Chair will be taken at three o'clock P.M. precisely.

The following papers are promised:—Dr. Mackey: Remarks on the Treatment of Skin-Diseases at General and Special Hospitals. Mr. F. E. Manby: On Rheumatic Hyperpyrexia.

Members are invited to exhibit pathological specimens at the commencement of the meeting.

BALTHAZAR FOSTER, M.D., } *Honorary Secretaries*
JAMES SAWYER, M.D., }

Birmingham, March 1875.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE next meeting will be held at the Harp Hotel, Dover, on Thursday, March 18th, 1875, at 3 o'clock: FRANCIS E. BARTON, Esq., in the Chair. Dinner at 5 o'clock precisely. Charge, 5s., exclusive of wine.

The Chairman kindly invites members and their friends to luncheon at his residence, 6, Cambridge Terrace, at half-past one.

Gentlemen who wish to make communications to the meeting are requested to inform me at once, in order that a notice thereof may be included in the circular convening the meeting.

EDWARD WHITFIELD THURSTON, *Honorary Secretary*.

Ashford, March 2nd, 1875.

WEST SOMERSET BRANCH.

THE spring meeting of this Branch will be held at the Royal Clarence Hotel, Bridgwater, on Thursday, March 18th, at 5.15 P.M. The following question has been settled by the Council as the one on which each member should be asked to express his opinion at the said meeting:—"What in your opinion is the best mode of treating habitual drunkards?"

Communication Promised.—Dr. Alford: On the Causation of Typhoid Fever.

W. M. KELLY, M.D., *Honorary Secretary*.

NORTH WALES BRANCH: INTERMEDIATE MEETING.

THE North Wales Branch held its intermediate meeting at the Castle Hotel, Conway, on Tuesday, February 16th, T. EVANS JONES, Esq., President, in the chair.

Letters of Apology for non-attendance were received from several members.

Officers of the Branch.—On the motion of Mr. T. DAVIES, Colwyn Bay, seconded by Mr. R. DAVIES, Llanfairtalhaiarn, it was resolved that D. Kent Jones, Esq., be requested to act as President for the ensuing year. Dr. Lloyd Roberts, Denbigh, was elected Treasurer, in the room of Dr. Turner Jones, resigned. Mr. T. Eytton Jones was elected Secretary.

The late J. Conway Davies, M.D.—Attention having been drawn to the death of Dr. Conway Davies, Holywell, who was President of the Branch in 1866-67, a warm vote of condolence with his widow in her bereavement was passed.

New Members.—The following gentlemen were elected members. Dr. Edward James Lloyd, Denbigh; Drs. Heaton and Davies, Wrexham; and Dr. Evans Hughes, jun., Llanrwst.

Papers.—The following papers were read. 1. Broken Bougie incrustated with Lithic Acid Deposit. By E. James Lloyd, M.B. (Denbigh). 2. New Steel Catheters. By E. J. Lloyd, M.B. 3. Fibrous Polypus of Uterus. By T. E. Jones, Esq., Llanrwst. 4. Craniotomy. By W. M. Williams, Esq., Llansantffraid. 5. Inversion of Uterus. By R. Davies, Esq., Llanfairtalhaiarn. 6. Mortification of Fingers. By R. Hughes, M.D., Conway. 7. Foetal Bones found in Uterus. By A. B. Steele, L.K.Q.C.P., Liverpool (read by the Secretary). 8. Gangrene. By R. Arthur Prichard, Esq., Conway. 9. Case of Opisthotonos, and Use of Ivory Dust as Nerve Tonic. By T. Eytton Jones, Esq., Wrexham. 10. Case of Paraplegia. By R. Hughes, M.D., Conway. 11. Case of Spina Bifida. By R. Davies, Esq., Llanfairtalhaiarn. 12. Case of Difficult Turning. By R. E. Owen, Esq., Beaumaris.

Dinner.—In the afternoon, the members dined together. The chair was taken by the President, and the vice-chair by the Honorary Secretary, Mr. Eytton Jones. A few friends, among them the Rev. R. Ellis (Gyffin), Mr. W. L. Banks (Bodlondeb), Mr. Warren (Llandudno Junction), and others, joined the professional gentlemen at the report.

SOUTHERN BRANCH: EAST DORSET DISTRICT.

THE first general meeting of this district was held, by the kind invitation of H. D. ELLIS, J.P., President, at his residence, Beech-hurst, Poole, on Thursday, February 18th. There were present H. D. ELLIS, Esq., J.P., President, in the Chair, and fifteen members of the Association and one visitor.

New Members.—J. E. Brine, Esq., Rowlands, Wimborne; W. Turner, Esq., and Hatton Smyth, Esq., M.B., Poole; James C. Leach, Esq., Sturminster-Newton; Woodruffe Daniel, Esq., Wareham; and G. W. Graham, Esq., Wimborne, were elected members of the Association, Branch, and District, James Tarzwell, Esq., of Sturminster-Newton, a member of the Branch and District; and P. W. G. Nunn, Esq., of Bournemouth, a member of the District.

Letters of Apology for non-attendance were read from Inspector-General Smart, C.B., President of the Branch, Dr. Ward Cousins, Honorary Secretary of the Branch, and others.

Introductory Address.—An admirable introductory address was then delivered by the President, "On the Advantages of the British Medical Association". After enumerating the more prominent of these, specially mentioning the part taken by the Association in obtaining the new warrant for the naval medical service, he went on to speak of the especial social benefits derived from the assembling of medical men at these district meetings in giving them opportunities of becoming better acquainted with each other, and promoting a spirit of fairness in their dealings with, and friendship between, professional rivals.

A short statement of the accounts for the past year was read by the Honorary Secretary.

Proposed Union with Bournemouth and West Dorset.—It was stated that the medical men of Bournemouth had formed a local society of their own, and that very few of them would join the Association and Branch; so that any union with them would be impossible, at any rate for the present. There was a general feeling of regret that the members of the profession at Bournemouth should hold themselves aloof; and a hope was expressed that they would soon be induced to form themselves into a district of the Southern Branch. There was a better hope of union with West Dorset; and the Honorary Secretary was instructed to write to Dr. Lush, Honorary Secretary of the West Dorset District, on the subject.—Other matters entered for discussion could not be settled until the question of union with West Dorset be answered.

A Vote of Thanks was proposed, and carried unanimously, to the President and the Honorary Secretary, and the meeting then terminated.

Dinner.—The members subsequently dined together at the London Hotel: H. D. Ellis, Esq., in the chair, supported by Dr. L. O. Fox of Broughton and J. E. Brine, Esq.

SOUTH OF IRELAND BRANCH: ORDINARY MEETING.

An ordinary meeting of this Branch was held in the Theatre of the Royal Cork Institution on Wednesday, January 6th, 1875: Dr. THOS. GREGG, President, in the Chair. There were present several members of the Branch, and a large number of students.

Removal of Nervous Bones.—Dr. H. M. JONES detailed the particulars of a case of removal of half the ulna, which was taken away (Dr. Gregg assisting) in consequence of extensive phlegmonoid erysipelas of the arm, and diffuse suppuration, resulting in necrosis. The want of early incisions had nearly resulted in the loss of the arm, which would have been most serious to an engine-driver, it being the right one; the man had now, however, returned to work, and the limb was nearly restored. The subsequent treatment consisted in the free use of permanganate of potash dressings, and support to the limb.

Removal of Cranial Bones.—Dr. HAYES of Tralee exhibited a patient from whom the parietal and frontal bones had been removed, in consequence of a severe burn received while in a drunken state last May. The particulars of the case have been already before the Branch (see BRITISH MEDICAL JOURNAL, January 2nd, p. 28). The PRESIDENT said, that the thanks and congratulations of the members were due to Dr. Hayes for his kindness in bringing forward the case, and the trouble he took in coming so great a distance to exhibit it.

Enucleation of the Eye.—Dr. JONES exhibited two eyes recently enucleated. In one, the operation was done for considerable staphyloma. The other was a case in which an eye, having been lost from choroid-iritis, was producing symptoms of sympathetic ophthalmia in the fellow eye. They presented the appearance usually seen in such cases.

Retraction of Gravid Uterus.—Dr. P. J. CREMEN read the notes of a case of retroversion of the gravid uterus. The woman, aged 30, was attended in the out-patient department of the Cork Maternity. Dr. Cremen was urgently summoned to deliver her. She had been there in labour over twelve hours; the nurse in attendance was puzzled as to the nature of the case, and the patient had not passed urine for nearly twenty-four hours previously. Surprised at not finding the os, and at the nature of the tumour (a large non-fluctuating mass, filling the entire cavity of the pelvis, not permitting the fingers to pass posteriorly between the tumour and rectum, and barely between it and the symphysis pubis in front), Dr. Cremen introduced a long gum elastic catheter, and drew off over half a gallon of urine. On the consequent reduction of the tumour, Dr. Cremen, on examining with the stethoscope, could find neither the fetal pulsations nor placental bruit. However, passing the flat hand, with considerable difficulty, above the tumour, he reached a large cavity or *cul-de-sac*, in which, discovering the limbs of a fetus, he seized them, and, after much labour and delay, succeeded in delivering the woman of a fetus about four months and a half old. The fetus evidently lay in this *cul-de-sac* after expulsion from the uterus, the mouth of which, on subsequent examination, he found turned completely upwards, and from which protruded the funis of the retained placenta. The subsequent steps of the delivery were completed. Dr. Cremen then, with comparative ease, replaced the retroverted uterus, and she recovered without a bad symptom. She remained in bed for a fortnight after labour, and the subsequent treatment consisted in cold vaginal douches, the administration of strychnine and iron internally, and the application of a Hodge's pessary. She menstruated regularly at the end of the second month from the labour, until the fifth, when she again became pregnant. In the third month of her pregnancy, the pessary slipped out, and, as she described

it, "the lump came down". On examination, Dr. Cremen again found the uterus retroverted, and readily replaced it by putting her in the knee-and-shoulder position, and introducing a Greenhalgh's spring pessary, which she wore for the ensuing two months. He withdrew it, and she went to the full time, and was confined naturally of a healthy child. She is at present again pregnant, the uterus now retaining its normal position.

Unilateral Convulsions in Typhus.—Dr. CREMEN read the notes of a case of unilateral convulsions in a woman, aged 30, who was admitted in typhus fever to the Cork Union Hospital in the fourth month of pregnancy, on December 31st, 1874. The fever was complicated with pneumonia. On the fifteenth day, she was seized with clonic convulsions confined to the left side; and these continued until the evening of the following day, the head being arched completely back (the fever at the time subsiding, and the maculae disappearing). On Jan. 6th, she had four severe attacks of convulsions; and, on the night of the same day, had a sharp attack of hemorrhage, which resulted in extreme prostration. On the 7th, she had two attacks of convulsions, from which date they ceased. She aborted on January 10th. There were intervals of complete consciousness between the attacks, and a complaint of a feeling of intense cold, great headache, and well-marked tenderness in the region of the cervical and upper dorsal vertebrae. The temperature and pulse were not much affected during the periods of the attacks, being nearly always 96 and 98 respectively. There was no albumen in the urine. The treatment, in addition to the local measures necessary for the pulmonary and uterine complications, consisted in free support, stimulants, enemata during the convulsions, leeches, succeeded by warm poultices along the tender spine, and bromide of potassium and ammonium internally.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 26TH, 1875.

GEORGE W. CALLENDER, F.R.C.S., F.R.S., Vice-President, in the Chair.

Antiseptic Japanese Paper as a Dressing for Wounds and Ulcers.—Mr. CALLENDER said that his friend Dr. Wallace of Colchester had forwarded to him some samples of Japanese paper, with a request that he would see if any use could be made of the material as a dressing for wounds. Only one of the samples appeared to him to be suitable for this purpose; but the qualities of this specimen of paper made it very serviceable as a substitute for lint, whilst it had the advantage over lint of being very much less expensive. He had tried it as a dressing for various wounds and ulcers, and in a case of deep-seated inflammation of the hand, with very good results. It had been used in all instances as prepared by Mr. Jepps, superintendent of the apothecaries' department at St. Bartholomew's Hospital, with antiseptic solutions in one of the two following ways. 1. Solution of salicylic acid and mastich. Take of salicylic acid forty grains; mastich sixteen grains; rectified spirit one fluidounce; dissolve the mastich in the spirit, add the acid, and shake till dissolved. 2. Solution of carbolic acid and muicilage of acacia. Take of carbolic acid one ounce; muicilage of acacia one ounce; water twenty ounces; dissolve the acid in the water, add the muicilage and mix. The strength of this solution might be varied, but it was desirable to prepare it for keeping of a greater strength than would be required for immediate use; first, to allow for the loss of carbolic acid from evaporation, and secondly, to permit the dipping of the prepared paper in water before it was applied as a dressing; a process which necessitated some further dilution of the acid. The mastich and the muicilage were added to increase the softness of the paper. Two sheets of the paper were placed together, a single sheet being rather too fragile, and were saturated with one of the above-mentioned solutions. They were then rapidly dried, and stored with others in tin boxes. When used, they might be applied dry to the surface of the skin or of a wound; or they might be moistened with water or with any kind of lotion after such application; or they might first be dipped in water or lotion, and then placed over the diseased or injured parts, just as lint was ordinarily used. The paper answered best when covered with oiled silk, so as to act as a warm water dressing. It appeared to be agreeable as an application. It was very readily adapted to irregular surfaces; and wounds and ulcers had healed rapidly under its protection. It was also available for carrying nungents and similar remedies, and seemed to be well adapted for use in various skin affections.

Elephantiasis Gracorum.—Dr. DUCKWORTH exhibited a patient, who was the subject of this affection in a severe form, as a contrast to Dr. Southey's case of anæsthetic leprosy shown at the last meeting. He was a well grown young man, aged 21, and was born in Calcutta. His father was born in Bordeaux, and his mother was of French extraction, born in Madras. He was suckled by his mother. When nine years of age, he came to England, and remained in good health, with the exception of the outbreak of some brown patches upon his arms and face. When twelve years old, his feet and legs began to swell, and some anæsthetic patches occurred upon them. Tubercular growths appeared upon the legs, face, and arms in succession. He now presented the leonine aspect and all the typical features of true tubercular leprosy, the face being covered with thick tubercular folds, and the lobes of the ears being greatly enlarged and thickened: numerous tubercular patches, some of which were softening, occurred over the wrists, arms, legs, and feet. The ulnar and the right peroneal nerves were enlarged. There had been albuminuria for the past two years. The case had been fully reported by Dr. Living in the Goulstonian Lectures for 1873, also by Dr. Duckworth in the tenth volume of *St. Bartholomew's Hospital Reports*. The man was for some time in Guy's Hospital under Dr. Habershon, and in the Glasgow Royal Infirmary under Dr. McCall Anderson. He was probably the first patient who in this country had been treated with Gurgun balsam, both as an outward application in the form of a lotion, and taken internally with lime water. The tubercles seemed to break down more readily under the drug, but the remedy could not be regarded as specific, as Dr. Gubler had affirmed it to be. Steel and a good dietary appeared to produce the most improvement. The patient had gained weight during his five months' stay in St. Bartholomew's. He passed on an average one-third less than the normal amount of urea daily. No renal casts were at any time found in the urine.

Discussion on Dr. Poore's Case of Paralysis of the Serratus Magnus Muscle.—Dr. BUZZARD said that he was disposed to doubt that the muscle was totally paralysed. Circumstances had prevented him from examining the patient, but Dr. Poore had mentioned that the arm could be readily raised above the shoulder, and this Dr. Buzzard thought was inconsistent with total paralysis of the serratus magnus. Moreover, the lesion was of traumatic origin; and it was, therefore, unlikely that both the nerve-supplies of the muscle—that from the intercostal nerves as well as from the long thoracic—had been obstructed. Agreeing that the paralysis probably arose from neuritis of the long thoracic nerve, he did not find the difficulty which Dr. Poore did in accounting for the delay which occurred in the appearance of the paralysis after the injury. It would be only when induration had succeeded to the serous effusion first resulting from the inflammatory process that sufficient compression would be exerted upon the nerve to obstruct its function. In Dr. Buzzard's experience, such a delay was most common. He referred to some cases, and amongst them to one in which paralysis and wasting in the extensor group of the forearm had commenced four weeks after a blow on the back of the shoulder in a railway accident, causing injury to the musculo-spiral nerve. It might be well, he said, to add that the condition had been verified by the measuring tape and electrical examination.

Dr. ALTHAUS agreed generally with Dr. Buzzard's observations. From his readings and personal observation of two cases, he could affirm that no complete paralysis of the serratus magnus could exist without interfering sadly with the motion of the arm. The chief symptom was the dislocation of the scapula, as already noticed, whilst, if the lower angle of that bone were pressed to the chest-wall, the patient, who was previously unable to lift the arm above the shoulder, could then do so at once. In a child who had bilateral paralysis of the serratus magni after whooping-cough, and in a man suffering from the disease, these points were in each case particularly noticed. In the child, the trapezius and other opposing muscles of the serratus were much hypertrophied. Niemeyer had recorded a case, in which a carpenter, who had carried heavy weights upon his shoulder, had thereby produced the disease. In another case, a tumour in the neck, by pressing on the nerve of Bell, had paralysed the serratus.—Dr. POORE said, that he thought there was complete paralysis in his case at the time when he had showed the man to the Society, and yet that man could raise his arm above the level of his shoulder. He had been unable to elicit any evidence of the slightest action on the part of the right serratus. Neither the base of the scapula, nor the ribs of the right side (the two points of attachment of the muscle) underwent the least change of position when that muscle should have been acting. This point was most clearly shown by means of the drawing and diagrams exhibited at the previous meeting. Possibly, at some previous time, the patient had exhibited the disabilities insisted upon by Niemeyer. The man was recovering from his trouble by compensation: there being now con-

siderable hypertrophy of the rhomboids and upper part of the trapezius, by which the base and spine of the scapula were fixed, and the raising of the arm accomplished. He had met with another case which presented certain points of similarity to the case now under consideration. Firstly, in the projection of the scapula; secondly, want of expansion of the chest on the paralysed side; thirdly, the bulging of those eight lower ribs to which the muscle was attached; fourthly, the absence of digitations of the serratus magnus. The two differed, however, in some particulars: this second case was not an uncomplicated one, as there was wasting of the upper part of the trapezius, and of the rhomboid muscles; and, as there was no compensation for the loss of the serratus magnus, therefore, the inability to completely raise the arm was well marked until the scapula had been pressed against the chest-wall. The second difference existed in the cause originating the mischief. This man slipped, and fell on his shoulder, and the paralysis followed in one week.

Case of Exceeding Unfrequency of Pulse.—Mr. PUGIN THORNTON brought forward a case in which the pulse had at one time made only 16 beats in the minute, and which for some weeks did not reach higher than 24 per minute. He showed a sphygmographic tracing of it when at 20 beats. The patient was a young married woman, upon whom, in

Tracing taken on January 4th, 1873, when there were twenty beats per minute. The small beat took place after every tenth pulsation.

1872, Mr. Thornton had performed tracheotomy for syphilitic laryngitis. Her pulse at the time of the operation was making 40 pulsations, and it was not until six weeks later, when she was re-admitted into the Hospital for Diseases of the Throat, in order to have the tracheotomy-tube removed, that the extraordinary unfrequency of her pulse was noticed. This infrequency was accompanied by transient attacks of an epileptiform character. It appeared that, in the summer of 1870, she was first seized with these fits, which at that time happened daily for about two months, the pulse averaging about 24 pulsations per minute. At the end of the two months, she completely recovered, and remained in good health until the autumn of 1872. Mr. Thornton read an account of these attacks, which had been kindly sent to him by Dr. Ransom of Nottingham, under whose care she had been in 1870. According to his account, a severe fit began with a sudden pallor of face, complete loss of consciousness, and motor power, the heart's action ceasing for several seconds (on one occasion, cessation of the heart's action was noted by stethoscope and watch for eighteen seconds). The respirations then became quickened and almost stertorous; the face flushed and the eyes suffused, fixed, and turned upwards. She foamed at the mouth. After a time, consciousness returned: the expression became calm, no signs of distress remained, and the intellect became clear. After recovery, the pulse returned to its normal rate of 24 beats per minute. During the latter part of the illness, she had hallucinations, which, after the fits were over, she clearly recognised as having been spectral illusions. The intensity of the fits was variable: they were sometimes so frequent that she had twelve in a quarter of an hour, and so transient that she was able on recovery to take up the thread of conversation. On one occasion, forty-five were counted in one hour. They occurred equally when she was in or out of bed, asleep or awake. Mr. Thornton remarked, that the woman, at the present time, was in good health, her pulse being constant at 48. She was still periodically

Tracing taken in April 1873, when there were forty beats per minute.

obliged to take iodide of potassium to stop the recurrence of the laryngitis, which occasionally threatened. He was at a loss to account for the curious phenomena, unless that the pneumogastric nerve might be presumed to be in some way affected by the specific poison. Unfortunately, the time of the syphilitic infection was in no way clear,

for Dr. Goldard of Pentonville, and Dr. Ransom, had no recollection of her suffering from any of the usual sequelæ of syphilis. In his own mind, there was no doubt that the unfrequency of the pulse was to be attributed to it. The instrument by which the tracings had been taken was one manufactured by Mayer and Meltzer. A pressure of 350 grammes was used in each observation.

Mr. CALLENDER asked, if in any earlier observations any notice had been taken of the frequency of the pulse. Was the unfrequency only recent, or had it occurred early in life? There were cases of extreme slowness of pulse associated with some injuries to the head; in such a case one always tried to ascertain the frequency of the pulse before the accident. In some cases of slowness of circulation, the patient seemed to suffer greatly from cold; but a patient of Mr. Callender's recently (St. Bartholomew's) had a pulse of 32 only, whilst a more robust man there could not be.—A MEMBER mentioned that in one of the earlier volumes of the *Médecine-Chirurgicale Transactions* there was a case recorded in which the pulse ranged from 25 to 7. After death, it was found that the foramen magnum was so contracted that it would hardly admit the tip of the little finger; and there was hypertrophy of the superior cervical ganglion of the sympathetic nerve.—Dr. SYMES THORNTON remarked, that the late Mr. Hodgson had a pulse which rarely exceeded 32; he was wont to draw especial attention to the fact that a slow pulse might exist for years without the production of any manifest symptom. He combated the notion that it meant a fatty heart. When the action was slow, any great exertion was apt to be exhausting, and exposure to cold was very hurtful.—Dr. SOUTHEY would like to ask whether Mr. Thornton had noticed that micturition was very frequent, or the quantity of urine very large. When digitalis was used, the action of the heart being very slow, the quantity of urine was often very large, the pressure on the renal capillaries being great. A man, aged 80, whose pulse had always been slow, usually from 18 to 20, and rarely reached 26 after exertion, had noticed the slowness for many years. Were fits associated with slow pulse? In this case the epileptic convulsions would seem to be associated with diminished supply of blood to the brain.—Mr. MAHONEY had taken sphygmographic tracings of a very slow pulse in a woman. The systole was not prolonged; but the diastole was much prolonged. Her pulse had been 65 before she was shut up in Paris during the siege, to which she attributed the change. Weakness, tendency to fainting fits, and the slow pulse had since ensued; the fainting being, perhaps, due to emptiness of the vessels of the brain.—Dr. ARCHIBALD HEWAN mentioned his own case. Twenty years before he had studied greatly; his pulse then was 72 in the minute. Afterwards it was found to be 55; from that point it had gradually decreased. Eight years ago, it was 24. Then Dr. B. Sanderson traced it with the sphygmograph. He had been abroad, never had a fit nor fainted, and could bear cold well. He had lately climbed a mountain many thousand feet high, and his pulse at the top was 40. His urine had not altered in any way; his digestion was very good, and he was in good health.—Dr. ALTHAUS said that the Emperor Napoleon the First had a slow pulse, and always felt uncomfortable, except in the excitement of battle, when it would rise to 60 in the minute.—Mr. THORNTON stated, that the pulse of his patient had not before her illness been noticed to be very slow. At the time of the operation it was 40; a few weeks afterwards it was 16. There was no valvular disease in this case. He had never heard that the urine was very copious, and would judge it was not so.—Dr. A. HEWAN mentioned that he had had rheumatic fever eight years ago, when his pulse did not rise above 32. Eight weeks ago he had gout and rheumatic pains, when his pulse quickly rose to 64 and 68; and then fell slowly to 32 and 28, at which it stood at present.

Excessive and Long-maintained High Temperature after Injury to the Spine: Recovery.—Mr. J. W. TEALE read notes of this case, in which a temperature ranging from 108 to 122 deg. and upwards had been maintained for a period of nearly nine weeks. The patient, Miss G., was thrown from her horse on September 5th, 1874, as the animal was trying to take a five-barred gate at a standing jump. The horse fell upon the lady, and rolled two or three times backwards and forwards over her chest, as she lay on the ground, which was covered with large rough stones. Temporary unconsciousness followed the accident, after which the patient was at once taken to Scarborough, and placed under the care of Mr. Teale. Her fifth and sixth left ribs were found to have sustained a simple fracture in the middle of their length; she was conscious, but collapsed, complained of great pain in the back, and was severely bruised at various parts of the body. For several days after the accident, there was some feverishness; the temperature reached 101 deg., but became normal in a fortnight. The ribs united readily; and the patient was apparently convalescing, though she had pain and tenderness over the spine, especially about the sixth dorsal vertebra. On October 3rd, Mr. Pridgin Teale of Leeds saw the case in consulta-

tion; and it was considered that the pain, and the slight feverishness which was again present, were due to subacute inflammation of the spinal ligaments. Perfect rest on a water-bed was advised. During October, the temperature remained at 100 or 101 deg.; there was pain, with tenderness, over the spine; sleep was disturbed; occasional twitchings of the legs occurred; and there was a feeling as of a cord tied tightly round the waist. The arms were unaffected. Leeches and ice-bags to the spine were employed; but the temperature slowly rose until, on November 3rd, it was 103.5 deg.; on November 6th, 106 deg.; and on the 7th, 107 deg. The respirations were unaffected; the pulse did not exceed 100. On November 7th, Mr. Pridgin Teale again visited the patient, and it was then thought that she had inflammation of the spinal ligaments and intervertebral substances, and possibly of the membranes of the cord, but that the cord itself was not primarily affected, except by pressure of neighbouring inflamed parts, as there was no paralysis of sensation or motion about the legs or sphincters. It was determined to bring the system gently under the influence of mercury, by means of ointment applied to the thighs. On November 8th, the temperature was 110 deg.; on the 11th, 12th, and 13th, it was 111, 113, and 114 deg.; whilst on the 14th, the index of the thermometer was buried in the bulb at the top of the instrument at a point above 122 deg. The pulse rose to 120, and became small, thready, and at times scarcely perceptible. Rapid emaciation occurred; there was intense pain along the spine, which was relieved by frequent hypodermic injections of morphia, and death from exhaustion seemed imminent. At times, the power of swallowing was lost, once for forty-eight hours; nutrient enemata were given, and ice-bags applied to the spine. On November 16th, the mercurial ointment was removed, the gums being slightly tender; and there was from that date an improvement in the general symptoms, though the temperature remained still as high as ever. The power of swallowing returned; the pulse fell to 110, and improved in quality; the spinal pain diminished; the twitchings in the legs were less frequent, and the patient could raise the legs more freely. The extraordinarily high readings of the thermometer ceased now to cause alarm, the patient having lived so many weeks with a temperature hitherto supposed to be incompatible with life. On December 12th, the tongue became suddenly swollen, causing great distress, which subsided in about twenty-four hours. Thenceforward more decided improvement set in. The appetite increased; flesh and power were regained more rapidly, though the temperature still ranged from 110 to 114 deg. On January 7th, 1875, the temperature fell to 104 deg.; on the 8th, to 102 deg.; and, on the 10th, it was normal. On the 12th, the patient could take a few steps about the room, a slight drag of the left leg being perceptible. On the 22nd, she walked one hundred yards in the open air. Mr. Teale thought that the result proved that the cord itself had not been seriously implicated, and that an excessive and long-maintained high temperature was not necessarily destructive of life. In some further remarks, he said that seven thermometers had at different times been used to register these high temperatures, four of which had been since verified at Kew. He exhibited the instruments and the accompanying certificates. Only one thermometer could be found which registered a temperature above 118 deg.; that one was marked up to 122 deg., and with that instrument the highest readings were taken. On December 1st, for the fifth time the index was buried in the bulb; as it was then found it still remained, and had been brought to the meeting for inspection. It was marked to 122 deg.; the index was in length equal to 3 deg., so that the temperature on December 1st would appear to have been at least 125 deg. The temperature was often taken in both axillæ at the same time; the instruments being reversed at each visit. The temperature between the thighs was generally found nearly to correspond with that registered in the armpits. Once, on December 10th, the temperature in the rectum was taken, and was found to be 111 deg., that in the axilla at the same time being 110.4 deg. The patient could never bear the thermometer to be placed beneath the tongue. The thermometers were inspected by two or three trustworthy witnesses before and after each application, and the results were always immediately recorded in writing. No hot-water bottles were near the axillæ, as had been good-naturedly suggested. Sometimes when the thermometrical readings were highest, the hands, feet, and forehead were icy cold. The urine, during the period of high temperature, was very scanty, and a mass of lithates; it was passed with difficulty into hot towels, so that neither the amount of uræa it contained, nor the specific gravity, could be estimated. It was found to be free from albumen on three or four different occasions. The bowels were relieved every third day by enemata; the menses recurred once after the accident at the proper date, and were then suppressed until January 26th, when they commenced and pursued a normal course. A large chart of the thermometric readings was exhibited to the members of the Society, and showed the rapid alteration of temperature which had occurred, without apparent alteration in the con-

dition of the patient; thus, on November 12th. at 10.10 P.M., the temperature was 113.6 deg.; on the 13th, at 4 A.M., it was 122 deg.; on the 13th, at 10 A.M., it was 114.3 deg. During seven weeks the temperature never fell below 108 deg., and rarely below 110 deg. Whether the high temperature was due to lesion of the ganglia of the sympathetic, Mr. Teale could not venture to surmise. There was never at any time distinct loss of sensation. The temperature was usually higher in the left than the right axilla; the left leg was now slightly the weaker; and it was the left ribs which were broken.

At the close of the paper, Mr. J. W. TEALE said he regretted that, since his paper had been forwarded to the Secretary, his patient had had a relapse, from which she was still in some degree suffering. After Miss G. had been convalescent for five weeks, he had reluctantly consented to her return home, and the effect of the railway journey, of 100 miles, had been in some measure to bring back the pain in the back, and a return of the high temperature, which had ranged from 105 degs. to 110 degs., and which was now again slowly falling. There had been no relapse of the more serious symptoms which had previously caused so much anxiety.—Mr. CALLENBER said that the temperature, pulse, and respirations of all his cases in St. Bartholomew's Hospital were taken twice daily. In no case of injury to the spine, with recovery, had he known the temperature to be above 107 degs. If the pulse and respiration, as well as the temperature, had been inserted on the chart, it would have been of service in elucidating the case.—Mr. THORNTON said that, in the case just narrated by himself, when the pulse was ranging from 16 to 24 the temperature was normal.—Dr. GREENHOW said, that rarely before had a case so unique or interesting been related to that Society. Cases of hyperpyrexia in rheumatic and typhoid fevers had been often under his care, but a rise of temperature so high as that in this instance he had never witnessed. He had seen a patient with a temperature of 110 degs., but never one to recover. If a patient with fever had twitchings and a rising temperature, he had felt that, unless the temperature could be reduced by cold, death was almost certain. This case negatived all he had taught for years.—Dr. FARQUHARSON said that the case afforded a very remarkable contrast to a case observed by Van der Kolk, in which, with dislocation of the first dorsal vertebra and injury of the spinal cord, the temperature fell to 82. Some observers held that, if the cord was injured near the brain, the temperature was high; others asserted the contrary.—Dr. MURCHISON had laid it down that in fever a temperature of 107 degs. was incompatible with life, even for a day. At *post mortem* examinations in such cases, fatty degeneration of the brain and heart was found to have occurred.—Mr. HUTCHINSON expected that one would have to take into consideration the cause of the high temperature in the different cases, and that the maximum temperature laid down by authorities as compatible with life in fevers would not apply to cases of injury to the spine. There were amongst these cases of injury two apparently opposite classes. After injury to the spine low in the neck, there might be very high or very low temperature without apparently any reason. A man who had received an injury to his cervical spine, producing paraplegia, had a temperature which never rose above 4 degs. below the normal. He was quite cold, even to the penis, which was turgid with blood, so that there was continual priapism; his face was quite cold, although he looked to be very well. He died on the fifth day. In such cases, however, there was mostly an exaltation of temperature, often to 110 degs. within twenty-four hours after the accident. He thought the mischief in Mr. Teale's case was in the spinal cord, although it was not a seriously disorganising disease.—Mr. PRIDGIN TEALE wished to add his testimony to the accuracy with which the case had been recorded. He himself took the temperature when it was at 110 degs, and three weeks subsequently at 114 degs. It was clear that we must give up the idea that temperature *per se* was an element of high danger. No injuries apparently were capable of raising the temperature so quickly to a high degree as those of the nervous centres. A gentleman, who at 5 A.M. received a compound fracture of his skull with crush of brain, was found at 5 P.M. to have a temperature of 109 degs., and was then dying. With apoplexy the temperature of the body often rose enormously. He hoped the time might shortly come when physiology might be able to throw some further light on these various points.—Mr. J. W. TEALE in reply said, that the pulse of his patient never exceeded 120, and was usually between 90 and 100. The respirations were never anything but normal, though sometimes excessively feeble.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MARCH 2ND, 1875.

GEO. D. POLLOCK, F.R.C.P., President in the Chair.

Molluscum Contagiosum.—The PRESIDENT handed round a photo-

graph of a case of *Molluscum Contagiosum*, at present under his care in St. George's Hospital, and on which he proposed on the following Thursday to operate. In this case the disease commenced at the age of six, and since then it has gone on increasing. These masses sometimes attain a surprising size, and a photograph of such a case was also handed around. These growths are very vascular, and the vessels are long and tortuous. He should proceed first to ligature that portion of the mass he proposed to remove, by passing needles through its base, and then tie the ligatures tightly. Without such precautionary measures dangerous hemorrhage might result.

Imperfect Teeth and Zonular Cataract.—Mr. JONATHAN HUTCHINSON introduced this subject in some remarks which are printed in another page.—The PRESIDENT inquired if all the teeth in the drawings exhibited were mercurial teeth. The answer was, All but two, which are syphilitic.—Dr. EDWARDS CRISP gave it as his opinion that the mercury had not much to do with the production of these teeth. In these children there was a history of fits, and he thought that the cause might lie in the condition of the nervous system. He had met with a French family, in all of whom there was mercurial trembling, and yet the teeth were entirely unaffected. In the case of a child of his own, which had been permitted to fall out of a perambulator, there had been fits, and its teeth were like those described.—Mr. HULKE said that he had listened to Mr. Hutchinson's remarks with great interest, but he ventured to think that other agencies were at work. Lamellar cataract occurred in the lower animals, and he remembered it in a cat of Mr. Bowman's years ago. There was no history of mercury there. Often only a single zone is affected; at other times there are several zones affected, with clear tissue betwixt them. A number of these, he believed, were produced early in intrauterine life, and are not produced afterwards.—The PRESIDENT said that, though feeling indebted to Mr. Hutchinson for his communication, for his own part he was inclined to follow Dr. Crisp's view. Inflammation in children would mark the nails, as his own experience in two illnesses showed. In the same way acute illnesses in children might mark the teeth, as he had observed in his own children, and in these cases there was neither mercury nor syphilis in action.—Dr. C. J. HARE thought that these teeth were associated with rickets. In rickety children the teeth were very liable to be marked, and that too in a form very like those exhibited. No mercury ought to be given in rickets, though it was often very useful in the treatment of infantile disorders. These teeth were not always seen where mercury had been given.—Mr. HUTCHINSON inquired if these teeth marked by rickets were the teeth of infants or of adults. The answer was, Of infants.—Mr. PUGIN THORNTON asked if there was any connection betwixt these mercurial and the syphilitic teeth.—Mr. T. SMITH said that mercury might be given to syphilitic infants, and they might grow up with these diseased teeth. As the last opponent of the use of mercury in syphilis had abandoned his position, these mixed teeth might be expected to be more common.—Mr. WARRINGTON HAWARD had seen in the Lancashire factory districts many children with marked teeth which could not be accounted for. There was no syphilis and no rickets, and probably they had not had mercury. Rickets were associated with convulsions, and mercury was given for the convulsions, not so much by medical men as in the teething powders sold so generally. He had seen a case of salivation produced by these teething powders.—Mr. HUTCHINSON, in reply, said that Dr. Crisp had raised a most important question; but in many cases where these teeth were found there were no convulsions. As to the production of lamellar cataract in cats, he thought they were more likely to have fits than to have had mercury. In cases where fits were long continued there might be two zones produced at two different periods. A small zone might occur in intrauterine life. Usually, however, these zones were infantile and not congenital. A small zone might easily be overlooked in early life. He did not think that mercury was the only cause of these diseased teeth. Stomatitis of a non-mercurial character, if severe, might produce them. Mercury was one, and also a most common, cause of these teeth. As to Dr. Hare's statement that rickets might occasion these teeth, Dr. Hare had admitted that the disease was in the temporary teeth, whereas his remarks applied to the permanent teeth. In rickets, the infantile teeth are much affected, but the adult teeth were good. There was no lamellar cataract in rickety children. The mercury given to syphilitic children was a common cause of these mercurial teeth. Often the teeth presented a mixed form. It was only when mercury was given in large amounts that the teeth became affected. They were quite different from those teeth called by dentists "craggy teeth", where large plates of enamel were defective. Craggy teeth ran in families.

Aneurism of the Heart.—Dr. BARLOW exhibited an aneurism of the heart, in a man aged 40, a plasterer, who had syphilis five years ago. For three years he had attacks of angina pectoris, and latterly he had had dropsy.

There were dulness in the third left intercostal space, and a systolic murmur at the apex, extending towards the axilla. The pulse was feeble, there was orthopnea, and the man gradually sank. At the necropsy, the pericardium was found adherent. There was regurgitation in the tricuspid, mitral, and aortic valves. The left ventricle was hypertrophied, and at the base there was a sac of the size of a small orange, to the left of the aorta. The edges of the aneurism were smooth. The sac consisted of fibrous tissue, much like an artery. This sac communicated with a sinus of Valsalva. There were only two patches of atheroma in the aorta. Both curtains of the mitral valve were thickened.

Case of Epithelioma.—Mr. HULKE showed three specimens of epithelioma. In the first case, the site was uncommon. It occurred in a woman who was admitted into the Middlesex Hospital in November 1873 with a cauliflower tumour behind the ear. It commenced as a knot and increased in size quickly. There was also giddiness, and she was deaf in the left ear. An abscess ultimately formed. The specimen showed a portion of the skull to be deficient, and the dura mater to be affected. The second specimen was from a man of fifty-six, whose hand and fingers were simply "dangling", from disintegration of the bones by cancer. At the time when he was vaccinated an abscess formed in his left hand, which broke and healed, and then broke again, all through life, until this ulcer formed. Old scars were very apt to become cancerous. The third case occurred in the forearm of a man of sixty-two, who had his hand crushed in childhood, and the wound did not heal for five years. The scar was tender, and then a wart grew. He used to pare this wart with his knife. At last, however, it formed a tumour.—The President asked if the same held good of psoriasis of the tongue.—Mr. HULKE said that the tough leathery covering almost always passed into epithelioma.

Malignant Disease of Testis in a Child.—Mr. HOWARD MARSH exhibited a case of malignant disease of the testis in a child of twenty-two months. In October last, the right testis was found to be enlarged. It was egg-shaped, $\frac{3}{4}$ of an inch by $\frac{1}{2}$. It was smooth. The epididymis was large and knotted. The swelling was firm but non-elastic. The cord was healthy; there was no pain. The case was watched, and as the swelling increased, two grains of grey powder were given daily. The testis grew rapidly, so it was removed, and the child went away into the country in a fortnight, quite well. The testis in structure was mottled and tawny. There were no traces of tubules anywhere. On microscopic section, it was found to consist of fibrous stroma with large cells. Such disease of the testis was not very uncommon in early life.

Aneurism of Aorta.—Dr. DOUGLAS POWELL showed a case of aneurism of the aorta, which came under his care in April last. The man was cachectic, and suffered from dyspnea. Six years ago he had lifted a heavy weight; he felt pain at the time, and had been ill ever since. The pulse was quiet. The arteries generally were diseased. There was a double murmur, and the area of cardiac dulness was large. In Dec. last, there were intense dysphagia, dyspnea, and orthopnea. There was a tumour in the front of the chest, extending from the third rib to the ensiform cartilage. Two points were very prominent. The pulse was quick and irregular, but there was now no murmur. On the necropsy, a tumour was found full of coagulated blood. The pericardium and left lung were adherent to the tumour. The oesophagus was generally contracted from compression. There was a globular aneurism of the aorta. The aortic valves were healthy and competent. There was a globular dilatation of the aorta about an inch above the valves, about six inches in circumference. From the point of this by an opening sprang an aneurism. It was flattened, about an inch in depth, while it was $3\frac{1}{2}$ in diameter. It was full of clots. The loss of the apex-beat, found in life, was due to this fluid tumour getting in front of the heart. There were no nerve-symptoms in life. The point of interest in the case was the large size of the aneurism. The dyspnea was due to it filling up so much of the chest-space. The man died ere the aneurism burst. Valsalva's treatment was carried out thoroughly, so that the man died of starvation. The man was a potter, and was often exposed to a temperature of from 200 degs. to 300 degs. Fahrenheit. There was much dust in the air, and he was always coughing. He drank much whisky, and had often to lift heavy weights. There was no history of syphilis. In 1856 he had rheumatic fever, but the heart was unaffected. There was a large area of dulness, a thrill at the third costal cartilage, a systolic murmur, and a very accentuated second sound. There was hypertrophy with dilatation of the right heart, general heart-symptoms, dropsy, etc. On the necropsy, the right ventricle was found to be greatly enlarged, but the pulmonary valves were healthy. The pulmonary artery was pinched, and there was an aperture in it. A scar, like a healed ulcer, was found above the anterior valves of the pulmonary artery. The left ventricle was hypertrophied, and the aorta diseased throughout: it was

pinched above the valves. There were several shallow pinches, and a scarlike surface in the aorta. There was general atheroma, much resembling that found with syphilis. Aneurisms opening into the pulmonary artery were recorded by Peacock and other writers.—The meeting then adjourned.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, JANUARY 30TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

Elephantiasis Arabum.—Dr. WHEELER showed the specimen described in the Report of the Surgical Society of Ireland, December 4th, 1874 (see page 146). Among the morbid appearances of the affected limb, was a marked thickening of the tunica adventitia of the popliteal artery.

Disease of Knee-Joint.—Mr. HAYES laid on the table portions of the bony structures of the knee-joint, which he had excised. The patient was a girl, aged 18, who had met with an accident to the joint eight years previously. The joint was externally globular in shape, and felt soft and pulpy. The patella was movable. The circumference of the limb at the knee was one inch and a quarter greater than that of the other leg. The morbid appearances were not well marked. Over the outer femoral condyle the cartilage was eroded, and below the cartilage generally lay a stratum of enlarged vessels. There was pulpy degeneration of the synovial membrane, and the posterior aspect of the patella was eroded.

Death shortly after Thoracentesis.—Dr. NIXON presented the thoracic viscera of a man, aged 22, who suffered from right pleuritis, with effusion. Bronchitis supervened. The apex-beat of the heart was displaced towards the left, being audible exactly beneath the nipple. The pleural effusion having rapidly increased, thoracentesis was performed, the point of puncture being between the sixth and seventh ribs and just within the axillary line. Four and a half pints of clear straw-coloured serum were drawn off. Vomiting set in during the evening, the respirations ran up to 70 per minute, the pulse to 150, and the patient died after a few hours. A large quantity of fluid lay in the pleura, and eighteen to twenty ounces of bloody serum in the pericardium. The heart was attached to the sternum by old lymph bands. Dr. Nixon considered that the fluid in the pericardium was due to *hydropericardium à vacuo*; and that collapse and engorgement of the right lung with blood, consequent on the drawing off of fluid from the pleura, had been the chief cause of death.

Giant-Cell Sarcoma of Lower Jaw.—The President showed a tumour of the lower jaw, which he had removed from a boy, aged 11. Eighteen months before, a small tumour was first noticed at the root of one of the canine teeth. It grew rather rapidly, and was an example of myeloid sarcoma. The normal bone was expanded so as to cover a large part of the growth. Microscopic examination showed the tumour to be a giant-celled sarcoma (Virchow).

Fractures of the Cranium.—Dr. BENNETT showed the skull of a man, aged 67, who had received a lacerated wound of the scalp in the left parietal region. A weight of thirty pounds fell thirty-four feet, and, having been checked in the fall at a distance of nine feet above the ground, struck the man over the temple. He died in a short time. There was an ordinary depressed fracture of the parietal bone, and a "fracture by radiation" was marked by a fissure extending from the depression to the orbital plate of the sphenoid bone, and passing into both optic foramina. The left lateral sinus was lacerated. The base of the cranium was fractured over each occipital condyle, and an oblique fracture passed outwards from the foramen magnum to end in the petrosal sinus. The transverse process of the first cervical vertebra was detached, the spine had been driven upwards, and was actually impacted into the cavity of the cranium. The posterior clinoid processes were also detached.

Ovarian Cyst.—Mr. CROLY exhibited a large unilocular cyst, which he had that morning removed by operation from a woman, aged 50. A second small cyst was attached to the sac.

Excessive Hypertrophy and Dilatation of Heart.—Dr. YEO presented the thoracic viscera of a labourer, aged 41, who had suffered from repeated attacks of rheumatic fever. He ultimately became the subject of aortic patency and weak heart; anasarca set in, and bronchial *râles* were general. Suddenly, a succession of attacks of hæmoptysis caused his death. Although the area of precordial dulness did not seem to be enlarged during life, the heart was found to be of enormous size. The left side was much hypertrophied and dilated. The right chambers were dilated and slightly hypertrophied. Both lungs were emphyse-

matous, and a bladder-like mass of inflated lung overlapped the pericardium, thus concealing the dulness caused by an enlarged heart. Some hard clots occupied the right ventricle. Localised, hard, airless spots existed in the lungs. These hæmorrhagic infarctions were probably the source of the fatal hæmoptysis. The arterioles leading to them were plugged. An embolus had evidently passed into the pulmonary artery, producing hæmorrhagic infarctions in the lungs and hæmoptysis.

Disease of Knee-joint.—Mr. HAYES showed a second set of morbid specimens from a girl, also aged 18, who had fallen on the affected knee four years ago. The changes were much more advanced than in the first case, scarcely a trace of cartilage being left over the tibial and femoral articulating surfaces.

SATURDAY, FEBRUARY 6TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

Central Necrosis of Shaft of Humerus.—Dr. STOKES presented a remarkable specimen. A man, a weaver by trade, aged 30, sustained a compound and comminuted fracture of both bones of the forearm. Amputation was in consequence performed just above the elbow-joint. The wound did not heal satisfactorily, and, unfortunately, the man was knocked down in the street, falling on the stump. Inflammation of the periosteum was set up, being accompanied by pain and great increase of size of the limb. Amputation through the shoulder-joint was practised after some time, but anasarca and albuminuria ushered in Bright's disease, to which the patient has since succumbed. The periosteum was most remarkably thickened, and in the masses of bone which had been laid down secondarily the osteogenetic properties of inflamed periosteum, as pointed out by M. Ollier of Lyons, were well exemplified.

Double Lesion of Aortic Valves.—Dr. HAYDEN laid on the table the enormously hypertrophied heart of a man, aged 53, who was admitted to hospital with oedema of the lower extremities, and *erythrosis*, or a reddish hue of the face, as distinguished from cyanosis. His respiration was irregular, and presented the Cheyne-Stokes' phenomenon. The area of precordial dulness was considerably increased, and at the base of the heart a loud and harsh systolic murmur was heard near the sternum. At the base was also heard a blowing slightly post-diastolic murmur, which was faintly audible at the apex. After death, the heart was found greatly hypertrophied; it weighed thirty-three ounces. A thrombus lay in the pulmonary artery. The right ventricle was not much thickened, but the left ventricle was greatly hypertrophied except at the apex, where its walls were attenuated. The mitral valve was healthy. The anterior aortic valves were incompetent, while from the posterior valve large calcareous masses projected into the opening, and evidently interfered with and postponed the regurgitation of the blood. Hence the postdiastolic second *bruit*. Dr. Hayden laid stress on the occurrence of Cheyne-Stokes' respiration in the absence of fatty change in the heart, calcareous deposits in the coronary artery, or atheroma of the aorta—the three pathological conditions supposed to be essential to the development of the phenomenon. Dr. Hayden considered that this form of breathing depended on dilatation of the aorta, a condition which was present in this case. He also alluded to Dr. Foster's views bearing on the indications afforded by the position where the diastolic murmur was heard (whether at the apex or at the ensiform cartilage) as to the valve which was incompetent in aortic valve disease. These views were directly opposed by the conditions in the present case.

Ulcer of Stomach.—Dr. FINNY showed the stomach of a man, aged 52, who on January 29 dined heartily off bacon and cabbage, having been previously in good health. Pain in the stomach occurred early next morning. He came into hospital with very little delay. On admission, there was pain in the hypogastrium and suppression of urine, with semicollapse. He died after a few hours. There were signs of recent peritonitis. In the anterior wall of the stomach, and just within the sphincter of the pylorus, there was a small round perforation. At the upper border of the stomach, an old cicatrised ulcer was found. This was especially remarkable, seeing the man had enjoyed good health.

Fracture of Os Calcis by Ecrasement.—Dr. BENNETT showed an os calcis, which had sustained a comminuted fracture. The patient leaped from a window in acute mania, and met with the accident. The soft parts were extensively lacerated, and gangrene set in, resulting in death. The specimen was illustrative of the second form of fracture of the calcaneum described by Malgaigne under the name *fracture par écrasement*. The other form was evulsion of the posterior portion by spasmodic action of the tendo Achillis: of this injury, Dr. Bennett also showed a specimen, and illustrated his remarks by Malgaigne's plate of the injuries of this bone.

CORRESPONDENCE.

THE CONTAGIOUS DISEASES ACTS.

SIR.—Dr. Parkes has again written in favour of the Contagious Diseases Acts, and, after calling upon me "to look at *the Army Statistics*", has again quoted statistics himself of two small regiments in two stations for a few months only: statistics privately obtained, and which I have no means of checking, and which may or may not be more accurate than Mr. Myers's private statistics of his own battalion, which gave exactly one-half the real amount of disease. It is strange that the advocates of the Acts, instead of appealing to the official reports of the whole army and navy, favourable and unfavourable alike (which are open to the profession), in order to prove their sanitary success, are continually putting forward private unauthentic figures of small bodies of men, which are, of course, supposed to be favourable, or they would not be selected, though, when figures were given by one of your correspondents (Mr. Myers) which did admit of comparison with the army reports, what was the result? Why, that in Windsor, which he had selected as a very strong proof of the efficiency of the Acts, the army reports showed that venereal sores had risen from the time of the introduction of the Acts, and were, at the latest published date, nearly twice as high as they were before the Acts were in operation. Dr. Parkes's own figures about the Royal Engineers at Chatham showed that primary syphilis had fallen 33 per 1000 in six years, or one-third, before the Acts were introduced; whilst it only fell 30 per 1000 in eight years afterwards. In Malta, by the two army reports, syphilis exceeded three-fold the average for the three years from 1869 to 1871: but this change is naturally not mentioned by the advocates of the Acts, though it is at least as striking as the difference between Portsmouth and Parkhurst in Dr. Parkes's last letter.

If, instead of taking two small regiments in two stations for less than one year, Dr. Parkes had followed his own advice to me, and examined all the army reports for the last twelve years, and also the navy reports since the Acts were in force, he would have found that, instead of gonorrhoea being double in the unprotected stations, it is the highest in the protected army stations, and has more than doubled in the protected home and Mediterranean navy stations since the Acts. He would have found that, whilst secondary syphilis fell from 31.26 per 1000 in the whole army in 1861, to 23.39 per 1000 (or more than one fourth) in 1866, it rose largely after the Act was passed, and is now higher (24.26 per 1000) than in 1866, and that the average of the six years has been 25.4 per 1000, or above one-twelfth higher than before the Act. In the Mediterranean station primary syphilis has nearly doubled since 1866, and in the home station there is less improvement than in any part of the world. Secondary syphilis has not increased in the home station in the navy it is true, but has fallen from 15.7 to 15.3 per 1000, &c. it has fallen in the navy, on the army, one-thirtieth, while it has risen in the army one-twelfth; and in Hong Kong, which is protected to an extraordinary degree, by the British government actually licensing the brothels, secondary syphilis bears a much higher proportion than it does in the army or navy at home. Instead of the introduction of the Act causing an abatement of disease, primary syphilis rose in Windsor from 58 to 136 per 1000, in Canterbury from 45 to 152 per 1000, in Shorncliffe from 42 to 77 per 1000. In Winchester it is now 16 per 1000 higher than it was before the introduction of the Act, and in Cork it has never been so low as it was two years before the Act. It is simply impossible to base accurate conclusions upon such a small number of men as the 1300 taken by Dr. Parkes for a few months in only two stations: and the average of 60,000 men or more in twenty-eight stations at home, and as many more stationed abroad, and taken for twelve years instead of twelve months, shows a sanitary failure which I put before Dr. Parkes in my last letter, and which he has not yet attempted to answer. The reply to Dr. Gore's letter is substantially the same as above. He writes about the periods of six months and one month, which are so short as to be quite inconclusive. As, however, he speaks strongly about the Curragh, it is necessary to mention that primary syphilis fell in it from 129 to 77 per 52 per 1000 two years before the Act was introduced, after which it rose again for three years, and that it has fallen 53 per 1000 in two years since the Act, and is now again rising. Dr. Gore's reference to the comparative severity of the cases in the protected and unprotected stations, is one upon which the army returns give no information: but the navy returns do give the average number of days sickness from each form of venereal disease in every station in the world, and from the tables on this point laid before the Home Secretary last autumn in my "statement" on the subject of the Contagious Diseases Act I extract the following.—"As regards

duration of primary syphilis, the home station occupies the worst position but one in the world, and the Australian (unprotected) the best; the Mediterranean is midway between best and worst. In gonorrhoea, the Mediterranean is the worst in the world, and the Cape of Good Hope and East Indies (partially protected) the best; the home station is midway. This certainly says little in proof that protection has reduced the severity of disease below its degree in unprotected places.

Yours faithfully, J. BIRKBECK NEVINS, M.D.

3, Abercromby Square, Liverpool, February 25, 1865.

SIR,—The important letter of Surgeon-Major Ffolliott of the 50th Regiment, in your last number, would have been even more valuable if the numbers had been stated per thousand; so I have thought it useful to respond to his invitation, and have worked them out, giving also the error (by Poisson's formula), and the range within which the truth would lie.

I.—50th Regiment at Colchester and Aldershot, under the Acts.

Year.	Average Strength.	Gonorrhoea.	Primary Syphilis.	Recruits who joined in Year.
1873 (12 months) 6551½	43	19	53	
1874 (7 months) 573	24	4	44	
Average strength 625.37	Total 67	23	97	
Average for a year of 12 months	42.32	14.53	61.26	
No. per 1,000	67.67	23.23	97.96	
Error by Poisson's formula (ratio to unity)	0.02841	0.01704	—	
Range within which the numbers might vary per 1,000	96.08	40.27	—	
	30.20	6.19	—	

II.—50th Regiment at Dublin, not under the Acts.

Year.	Average Strength.	Gonorrhoea.	Primary Syphilis.	Recruits who joined in Year.
1874 (5 months) 550	15	25	Nil.	
1875 (1½ „) 517	10	10	Nil.	
Average strength 542.38	Total 25	35	Nil.	
Average for a year of 12 months	44.44	64.44	—	
No. per 1,000	81.93	118.81	—	
Error by Poisson's formula (ratio to unity)	0.03331	0.03029	—	
Range within which the numbers might vary per 1,000	115.24	158.10	—	
	48.62	79.52	—	

It will thus be seen that, as regards syphilis, the superior limit of possible ratio in the period under the Acts is only *one-half* of the inferior limit, and only *one-fourth* of the superior limit in the period not under the Acts; whilst the simple average per thousand is more than *five* times in favour of the Acts. Even in gonorrhoea, which is obviously less under control, the numbers are considerably in favour of the Acts, to the extent of about 22 to 25 per cent. Again, taking the numbers as given in the successive periods, we have

I.—Period under the Acts.

Year.	Average Strength.	Gonorrhoea.	Primary Syphilis.	Recruits.
1873 (12 months) 6551½	43	19	53	80.6
1874 (7 months) 573	24	4	44	132.0
Admission per 1,000 per annum	67.67	23.23	97.96	
Ratio per 1,000 of strength.	—	—	—	

II.—Period not under the Acts.

1874 (5 months) 550	15	25	Nil.
1875 (1½ months) 517	10	10	Nil.

Here we see that, during the period under the Acts, syphilis diminished 57 per cent., in spite of a mean amount of nearly 10 per cent. of strength as recruits. Gonorrhoea slightly increased (about 10 per cent.), probably due to the recruits, as the increase in their number was considerable (56 per cent.) in 1874. On the other hand, in the period not under the Acts, the syphilis shot up, in the end of 1874, more than 800 per cent.; whilst the first month and a half of 1875 showed an increase of over 40 per cent. even on this large number, or no less than *twelve hundred* per cent. above the ratio of the first seven months of 1874. In the gonorrhoea, although there was at first a slight diminution (about 9 per cent.), due probably to no fresh recruits being taken, a large increase (more than 240 per cent.) took place in the beginning of 1875. It may be objected that the length of the second period is only one-third of the first, and the objection is so far a legitimate one; yet it may also tell another way, as showing the great rapidity with which the evil influence acted in the time. But, if we compare the seven months of 1874 at Colchester and Aldershot under the Acts with the

six and a half months at Dublin (1874-5) not under the Acts, we shall have two periods of almost the same length, and very fairly comparable.

	Average Strength.	Admissions Total.	Admissions per 1,000.	Recruits Total.
1874 (7 months under the Acts)	573	24	4	71.80
1874-5 (6½ months not under the Acts)	550	25	35	81.93
				118.81
				Nil.

Here we have most telling figures, for the mean strength is almost the same, as well as the length of the periods, and we have a rise of 14 per cent. in the gonorrhoea and no less than 900 per cent. in the syphilis, although the first period was under the adverse influence of 13 per cent. fresh recruits, whilst none were enlisted during the second.

I am, Sir, your obedient servant,

F. DE CHAUMONT, M.D., Surgeon-Major.

Army Medical School, Netley, March 2nd, 1875.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Monday, March 1st.

Water-Supply.—Lord CADOGAN inquired whether the Government intended to take any steps for the introduction of a measure during the present session with a view to obtaining a better and purer supply of water for the metropolis.—Lord BELPER referred to the bad state of the water supplied by the Chelsea Waterworks Company, and thought that some pressure should be put on them in order to compel them to provide water of a purer description.—The Duke of RICHMOND replied that it certainly was not the intention of the Government to introduce any measure for the purpose of acquiring all the waterworks in the metropolis; and, with regard to Chelsea, a Bill was now before Parliament for the improvement of the supply of water there, and it would, therefore, be premature to introduce at present any compulsory measure with respect to that district.

HOUSE OF COMMONS.—Monday, March 1st.

Rivers Pollution Bill.—In reply to Mr. Stevenson, Mr. SCLATER-BODDIE said he hoped to be able to introduce the Pollution of Rivers Bill before Easter.

Tuesday, March 2nd.

The Inquest on Sir Charles Lyell.—In answer to Mr. W. Cartwright, the HOME SECRETARY observed that the accounts which had appeared in the public press relating to the circumstances under which an inquest had been held on the body of Sir Charles Lyell were entirely true; and that if he (Mr. Cross) were sitting as chairman of quarter sessions, and had to consider whether the inquest ought to have been held, he should strike it out of the list as, in his opinion, a great outrage upon decency. The Secretary of State had no jurisdiction over any coroner, and the power of dismissal rested with the Lord-Chancellor. He had, however, felt it to be his duty to write to the coroner for an explanation of his reasons for holding the inquest. The letter he had received in reply, however, gave no reasons that seemed to justify his proceedings. Feeling strongly on the matter, he had written to the Lord-Chancellor on the subject, and left it in his hands to deal with it as he thought proper.

Burials in Westminster Abbey.—Mr. CROSS, in answer to Mr. Neville-Grenville, said he had communicated with the authorities of the Abbey and with other persons; and he was told that the average number of burials had not, for the last two-and-twenty years, exceeded one a year; and that every possible precaution was taken to prevent damage to the fabric, and also to prevent injury to the health of anyone. He believed there was not the slightest danger arising from burials.

Wednesday, March 3rd.

Universities (Scotland) Degrees to Women Bill.—Dr. LYON PAYFAIR presented a petition from the University of Edinburgh against the Bill.—Mr. COWPER-TEMPLE moved the second reading of the Bill, which he explained to be in the nature of a simple declaratory Act. The Universities of Scotland Act empowered the University of Edinburgh, with the consent of the Chancellor, and after communication with the Senate, to make internal regulations for the government and guidance of the institution, and in the belief that they were authorised to extend the teachings and examinations to women, regulations had been made accordingly. Doubts had, however, arisen as to the legality of those regulations, and it appeared that, if such a power was to be established, it must emanate from the Crown or the legislature. All this Bill did,

therefore, was to declare the desirability of extending the benefits of the universities to female students, leaving it to the authorities to do so or not. Opposition to the proposal had come only from the medical profession, who were jealous of admitting females to compete with them in the practice of medicine and surgery. At the present moment, all the universities of Europe were open to female students; even Russia was in advance of us in this respect; and if young women would qualify themselves to practise medicine, it was strange that, in a country like England, they should be deprived of the legal rights and status belonging to the profession.—Mr. MAITLAND moved the rejection of the Bill. He said that if it were passed into law the Scotch Universities would become the scene of perpetual agitation. It was altogether wrong to say that doubts existed respecting the power of the Universities to admit women as students and grant them degrees. His principal objection to the Bill was, that it asked Parliament to hand over its power to the University Court. Parliament was the only proper judge of a matter that affected the position of women. Moreover, a serious financial charge was involved; for if the Bill passed they would next have the University Court coming to the legislature for money to enable them to provide separate buildings and additional professors for teaching female students.—Sir W. ANSTRUTHER seconded the amendment. He stated that the admission of ladies was a result of a pardonable anxiety on the part of the University to meet their wishes, and of a mistaken exercise of power. What had been granted as a favour, however, the ladies now claimed as a right; but the claim, on being legally tested, was found to be untenable, and now Parliament was asked to reverse the decision of the highest court of law in Scotland. In his opinion it would be better for the ladies and their friends to establish a medical college of their own.—Dr. CAMERON pointed to the fact that women were prepared to pay whatever expenses were necessary, whilst their friends had subscribed £60,000 for new buildings for the University of Edinburgh.—Mr. FORSYTH spoke in support of the Bill, and combated the argument of women's unfitness for the medical profession.—Mr. BERESFORD-HOPE's objection to the measure was that persons who were engaged in a very wide crusade were taking advantage of a small issue and a local grievance to obtain a decision in their favour on a much larger and serious question. In fact, under the cloak of a Scotch grievance, they were trying to establish a precedent for the whole kingdom.—Mr. E. NOEL opposed the Bill.—Mr. ORR EWING would vote for the second reading, though he did not concur in all the objects of the Bill.—Mr. J. M. STEWART objected to the measure.—Mr. M'LAGAN supported it.—Dr. PLAYFAIR pointed out that the object of the Bill was not only to admit females to education, but enable them to graduate in arts, medicine, law, and divinity. The measure showed a profound ignorance of the constitutions of Scotch Universities, and even if passed it would not advance the intentions of its promoters a single step.—Mr. STANSFELD would give an earnest and hearty vote in favour of the Bill.—Mr. ROEBUCK was no advocate of what were termed "strong-minded women", but he saw no harm in allowing the Scotch Universities to grant them medical degrees. He thought there was no answer to the case put forward on behalf of those females who prayed Parliament to enable them to earn their livelihood in a fair, honourable, and upright manner. He was persuaded that the opposition of the medical profession was influenced by a coward fear that they would find successful competitors among women.—The LORD ADVOCATE was at a loss to understand why it was proposed to deal with the northern University only, and exclude those of Oxford, Cambridge, and London. Further, if it were right to confer degrees upon women, the power to do so ought to be compulsory, not permissive.—A short reply from Mr. COWPER-TEMPLE was followed by a division, and the loss of the Bill by a majority of 43, the numbers being 194 Noes, and 151 Ayes.

MILITARY AND NAVAL MEDICAL SERVICES.

RECENT ARMY MEDICAL EXAMINATIONS.

A MILITARY correspondent writes to us: "Kindly permit me to point out the results of the last, so-called, competitive examination for the army. Eight candidates were accepted for the Royal service, and twenty for the Indian; for the former there were twenty-five vacancies and twelve candidates; for the latter, twenty vacancies and forty candidates, all of whom were declared qualified. The British candidates obtained an average of 1,886 marks each; the Indian, 2,137, a difference of 251 per head in favour of the latter; but if the first eight men for the Indian service be taken, the average is raised to 421 per head in favour of the Indians. The *Broad Arrow* of February 27th, states that commissions in the Royal service were offered to men who were

unsuccessful in the competition for the Indian service. Can this be true? One thing was very evident before the examination. The India Board went honestly into the market, and said, 'We want twenty men', and they got them; while, for the British service, it was advertised that 'an examination will be held' thus leaving it open to the authorities to 'cut their coat according to their cloth', and accept or reject as many as they liked, and say afterwards, 'that is the number we required'; an honest proceeding truly. Is anything to be done to allay the present state of burning discontent which has now spread from the department and taken deep root in the medical schools, as evidenced by the result of the late competitive (?) examination."

THE ARMY MEDICAL SERVICE.

SIR,—No doubt, a great difference of opinion exists at the present moment amongst the officers of the army medical department on the subject of "systems"—whether the old "regimental", the "unification", or a "modified regimental", would best meet the requirements of the service, and tend most to the comfort of the British soldier and his medical attendant alike; but I am of opinion that, as far as the junior officers of the department are concerned, this is not a time to talk about "systems", but about the main points concerning their own immediate welfare. No one can have more at heart the well-being of the British soldier and the requirements of the service, I am sure, than the medical officer; but the latter, being formed of the ordinary stuff which goes to make up that strange compound termed "human nature", has wants and requirements of his own as well as those about him, and cannot see why his interests alone should be so little thought of now-a-days. I think we, of the junior grade, are all agreed on the following points, namely:

1. That all surgeons of fourteen years' service and upwards should be at once promoted to the grade of surgeon-major.
2. That officers of the administrative grade of sixty years of age and upwards should be invited to retire; and
3. That the rule regarding the retirement of surgeons-major, on their attaining the age of fifty-five years, be strictly enforced.

I think all sensible and just-minded people will admit that it is simply ridiculous to expect that, while A. B. has enjoyed the emoluments (such as they were) of the upper grades for a period consisting of three-fourths of his service, Y. Z. is quietly to submit to remain in the lowest grades for more than half his entire service.

I am, Sir, your obedient servant,

February 24th, 1875.

PROMOTION.

SIR,—In a recent issue of the BRITISH MEDICAL JOURNAL, an able article appeared, detailing the obstacles that at present exist to army medical reform. It is only too true, as the writer observes, that there is a want of unanimity as to the required changes in the organisation of the department; and, so long as those conflicting views and differences of opinion are put forward, it is difficult for the authorities at the Horse Guards or War Office to come to any conclusion, or decide what is best to be done for the benefit of the service. It could scarcely be expected that the originators and supporters of the unification or general corps system would abandon their pet scheme, or revert to the regimental system again, without a struggle; and their complaint now is, that it has not had a fair trial, inasmuch as all medical officers were not removed from their regiments and placed on a general roster for duty at the station hospital and foreign service. Surely they would not for a moment advocate anything so unjust simply to test a system that has so completely failed and broken down in its infancy, and that is condemned alike by commanding officers and men, and the majority of medical officers in the service. Since station hospitals were established here, the sick list steadily increases, notwithstanding the efforts that are made to keep it down by discharging men from hospital before they are convalescent, and detaining men day after day until eventually they are obliged to be admitted. In one hospital, the number has increased from 200 to 280, and in another from 140 to over 200. Trivial cases are much longer under treatment than formerly, when a hospital sergeant saw that the instructions given by the surgeon were carried out; yet the strongest arguments we hear urged in their favour are "economy and efficiency". They certainly are not more efficient, and I doubt if they will be found more economical, than the ordinary regimental hospital.

Take the case of Dublin, where three ambulances are employed daily in conveying the sick from regiments to hospitals. Each ambulance has a corporal in charge, and a driver of the Army Service Corps; if to expenses such as these are added the pay of captain of orderlies and his staff of sergeants, ward-masters, and assistant ward-masters, the increase in the number of sick, and the facilities afforded for those inclined to

prolong their stay in hospital of doing so, I think it will be found in the end that the regimental hospital was not only the most efficient, but the most economical of the two.

I have spoken to a number of medical officers, with the view of eliciting the general opinion on the suggestions that have been made for the reorganisation of the department, and they one and all say they would be satisfied with the scheme proposed by Surgeon-General Mouat, and which there is every reason to believe would meet with the approval of the authorities of the Horse Guards. The modified regimental and general hospital system would meet all the requirements of the Service in times of peace or war, and the concession of the few privileges asked for would, I am convinced, tend in a great measure to allay the feelings of discontent that exist at the present time amongst the executive rank in the department.

The administrative branch of the service were in no way touched by most of the changes that have occurred since April 1873. All of them have belonged to regiments at some period of their service. Some look back with feelings of pride and pleasant remembrance to their former association with their regiments, where, socially and professionally, they were much esteemed. It is, therefore, the more difficult to imagine why they should advocate a system that prevents the juniors entering the service from partaking of the many advantages they acknowledge themselves a regimental training has to recommend it, being the only school in which a young surgeon has an opportunity of learning anything of the habits of soldiers, customs of the service, discipline, etc., and so strenuously oppose the reintroduction of the regimental system in any form. Dr. Edward Hamilton, in his excellent pamphlet *on the Present State of the Army Medical Service*, tries to account for this opposition, and attributes it more to love of power than any desire to improve or benefit the Department. He says:—"Such is the thirst for military command among certain persons, that, if the Army itself must still be left to the combatants, the plan adopted to secure the coveted delight is to create a little army within the greater, and call it a department. We see this spirit in full force in the unification scheme." Let us hope that it is neither desires of this kind nor their own personal interests that influence their opposition to the wishes of the majority of army medical officers.

I am, etc.,

SURGEON, A.M.D.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

GLANFORD BRIGG RURAL SANITARY DISTRICT.—This district lies between the Trent and the Humber. According to the report of Mr. Moxon, "it is probable that in no part of the kingdom have general and subsoil drainage, and other agricultural improvements, made a greater change in the aspect and fertility of the country, and, incidentally, in the health of the inhabitants". Years ago, ague, and fevers were prevalent; now the former disease has entirely disappeared from the district, and the latter are much less common. Within Mr. Moxon's memory, the consumption of quinine as a remedy for ague was "enormous"; but, as a consequence of the good general drainage which has been carried out, the disease has practically been abolished. The habit of opium-eating, however, which Mr. Moxon believes to owe its origin to the desire to alleviate the distressing sensations of constant ill-health, still prevails in the district, though not to the same extent as formerly. It appears that the population is, on the whole, comfortably housed, and, though it consists mainly of agricultural labourers, the people generally are well fed and well clothed. Last year, the birth-rate was 33.75 per 1000, and the death-rate 17.5, the death-rate for the whole of Lincolnshire during the past twenty years having been somewhat over 19 per 1000. But, notwithstanding the improvements in land-drainage, Mr. Moxon states that the sanitary condition of the district in other respects has not improved, the annual death-rate during the ten years ending 1870 having been the same as during the previous decade. Many of the villages are either undrained or only partially drained, and in several the water-supply is insufficient, while nuisances connected with privies, pigstyes, cesspools, and defects in the sanitary condition of houses are common. The only work done by the sanitary authority during the year was the abatement of isolated nuisances. Although these amounted to 327, as the district, according to the census of 1871, contains a population of over 26,000, the number of nuisances removed, to say the least, does not appear to be excessive. The report is very well written and arranged, but it loses in value from

the apparent timidity with which the medical officer of health submits his recommendations. If villages are badly drained or have no sufficient supply of water, Mr. Moxon ought to have no hesitation in pointing out these defects in each case, and insisting on their removal.

BOLTON.—The Report issued by Dr. Livy, the medical officer of health for this borough, is a lecture on the general principles of public health as exemplified by conditions prevailing in Bolton, rather than a report on the sanitary condition of the place. It is, however, calculated to be useful to the sanitary authority; and it contains a considerable amount of valuable information. Bolton lies on a series of sandstones and shales, intercalated with beds of coal and fire-clay. The superficial deposits over a considerable portion of the municipal area consist of clay deposited during the glacial periods; and, as the borough lies in a hollow, this clay contributes to the unhealthy nature of the site by being all but impervious to water. This condition points to the necessity of a deep system of drainage, which shall carry off the subsoil water. The water-supply for Bolton is highly spoken of. It is derived from a series of hills composed of the millstone grit; it is soft and pleasant to drink; and it contains sufficient saline matters to prevent its having any dangerous action on the lead service pipes. In speaking of the various systems of excrement disposal, Dr. Livy condemns the use of water-closets in towns. He considers that they convert the sewers into elongated cesspools, and hence cause much offensiveness; and he objects to the large volume of water necessary to their proper management. The matters which the sewers contain in a water-closet town are stated to adhere to the sewers, and hence to pollute all the surrounding atmosphere. We do not wish to imply that the water-closet system is without drawbacks; but we think that many of the objections urged against it apply rather to ill-managed and imperfect systems, which are capable of being much improved. Where water-closets exist, they are unquestionably capable of much harm, unless they are connected with a really efficient and well-ventilated system of sewerage; but, on the other hand, the dry system of excrement removal, which answers admirably in institutions, in villages, and in those portions of towns where they can be under the constant surveillance and control of the authorities, is difficult of management in the large houses of the upper classes of town residents. Dr. Livy's Report implies that, in Bolton, common privies are connected with the sewers. Nothing can possibly be more objectionable than this. Such a system embodies all the filthiness of a closet with wet contents, and all the dangers of a system of sewers the use of which has been utterly perverted.

SHEFFIELD.—Dr. F. Griffiths has issued an elaborate report of the health of his town during the past year, in which every subject which comes within the ken of a medical officer is dealt with in an able manner. The population of Sheffield at the time of the last census was 239,946, which, with the excess of births over deaths for the three years subsequent, amounting to 10,659, gives a total of 250,605. The steady increase of births over deaths which has taken place indicates a concurrent prosperity of the population. The death-rate of the town is high, amounting in all to 6.558, or 26.61 per 1,000; of this number, 1,954, or 29.79, of the total deaths which occurred were of infants under one year of age. A great deal of this high rate of infant mortality is due to impure air, bad nursing, improper food, exposure to cold, narcotics, and neglect. Dr. Griffiths has prepared a set of simple rules for the guidance of mothers in the management of their infants, which might be judiciously and efficiently distributed by the registrars. The seven chief zymotic diseases caused 1,233 deaths; of these, diarrhoea killed 425, and small-pox 5 only against 600 deaths in the previous year. The number of vaccinations performed amounted to 5,685. In consequence of this, and of the greater cleanliness and strict inspections, the small-pox epidemic has been almost entirely stamped out. Scarlet fever, measles, and fever, including all kinds (excepting scarlet), carried off together 637. Scarlet fever is always present, and no week passed without some deaths. This disease, together with measles and whooping-cough, is conveyed chiefly by children who are sent to school before they have sufficiently recovered, and whilst they are still in a highly contagious state; and means have been taken to arouse teachers to a sense of the dangers they incur from allowing partly convalescent children to mix with the healthy and uncontaminated ones. The other chief causes of zymotic disease are the unwholesome dwellings and common lodging-houses which abound in the town, with their usual accompaniment of defective drains, closets, and sewage. A strict enforcement of the Common Lodging-house Act is strongly needed. At present, these houses are nests of crime, immorality, and disease. Thieves, tramps, and beggars congregate and migrate as well as import and transport from place to place both moral and physical pestilence.

Energetic measures are required to suppress these horrible places. The closet-system of the town is, generally speaking, very defective; the closets are invariably constructed on false principles, and are placed too near the houses. Dr. Griffiths has shown himself to be no mere theorist in these matters, but gives specifications, and working drawings with elevations, and transverse and horizontal sections of an improved system of combined privy, refuse-bins, and ash-pits, which he himself has invented. This system possesses the great advantage of being cheaply constructed, and readily adapted to existing privies. The closets are thoroughly efficient and inodorous, and do not require to be so frequently emptied, as is the case with the pail system of closet. Dr. Griffiths speaks highly, as he has a right to do, of his combined plan; practical experience having proved its ready utility and economy. The escape of sewer-gas through overflow-pipes is a frequent source of complaint; the curved syphon-water-trap is pointed out to be a gross and dangerous deception. The constant pollution of the rivers is a source of great regret. In those parts of the streams especially which pass through the inhabited parts of the borough, the banks are being narrowed and the beds gradually silted up with refuse of every kind. In dry weather, the beds are little better than stagnant and offensive pools; and, were it not for the flushing following rainfall, the streams would certainly become the foci of disease and death. It should be understood that slimy matter brought down these rivers in flood-time kills the roots of the plants which have held together the earth on the sides, and thus renders the shores liable to abrasion and to be washed away at the next flood. Private slaughter-houses are among the worst nuisances in the borough; they are all situated too close to dwelling-houses, while they afford the greatest facilities for slaughtering diseased animals and for the sale of unsound and unwholesome meat; they are seldom clean even after the filthy waste and washing have been carried into the sewers. Cow-houses, stables, and pigstyes are often found in yards and courts of very limited area, and too close to dwelling-houses. The cow-houses are seldom clean, and still more seldom supplied with water, whilst dairy operations are carried on in small rooms contiguous to the cow-houses, in which all other household duties are performed, and in which members of the family are occasionally suffering from disease. Milk stored in such premises cannot remain long uncontaminated, and, unless it be quickly consumed, is certain to absorb poisonous effluvia. Enteric fever has been clearly proved to have been carried from dairies, and spread amongst large classes of persons who used the milk conveyed in vessels improperly washed in impure water. In Wolverhampton, out of 18 cases of typhoid fever, 15 of the patients had been supplied from the same dairy where the disease existed. Hence the importance of the utmost cleanliness in regard to milk. Dr. Griffiths's remarks upon the working of the Act are cogent; doubtless, however, they were written before the Sanitary Acts Amendment Bill, passed August 7th, came into force; but, as the sanitary laws are still incomplete, and have been promised further amendments and consideration during the next session, the suggestions given are worthy of careful consideration. Theoretically, the Sanitary Act is lamentably defective; for, while it recognises the fact, that epidemics can be controlled in their violence, and their disastrous effects minimised by proper sanitary efforts in the early stages of an outbreak, it has entirely neglected to provide the machinery necessary to make the sanitary authority aware of the existence of disease, until it has taken a strong hold upon a locality, or until the epidemic has actually slain many of its victims. At present, the only source of reliable information is the local registrar's returns of deaths. To visit a locality after the disease has expended its violence, debilitated the strong, and killed off the weakest, and to offer advice when the evil has culminated, seems little better than a mockery or an absurdity. The efficient working of the Act should not be permissive, nor one of mere suzerainty. Wherever the word "may" occurs, it should be altered into "shall" or "must". To be really effective, it must provide for—otherwise provision must be made for—the supply of information upon which officers can act both promptly and intelligently. The only way in which information as to the existence of disease can be obtained, is to adopt means to obtain regular weekly returns from the whole of the medical profession, or at least from gentlemen who are Poor-law medical officers. The expediency of enlisting the present Poor-law officers on the sanitary staff is strongly urged. Those gentlemen, from the intimate knowledge which they possess of their respective districts, and their familiarity with diseases and its surroundings in all forms, are peculiarly well qualified to discharge the duties of medical officers and sanitary inspectors. It would be well if parents, guardians, and employers of labour, and schoolmasters, could be induced to give notice, either personally or in writing, to the medical officer within an early date of the outbreak of any contagious or infectious disease. Such an enactment would meet nearly all the requirements. Such a plan was adopted during the cattle-plague, and the early information

thereby obtained was the means of stamping out the disease. It is reasonable to urge that a regulation which checked disease amongst cattle could surely be carried out similarly to benefit human beings. A form of questions has been prepared for this purpose, and it is earnestly requested that these forms will be filled up and returned to the medical officer whenever the existence of disease renders it necessary. The total number of nuisances reported upon by the district inspectors during the year was 2,296—a heavy black-list certainly; but the cleansing and purification of a town like Sheffield is truly an Augean task. Fortunately the duty has devolved on an officer who is not likely to give up until all that human means can do has been done, and done well too. Dr. Griffiths complains of the inefficiency and incompleteness of the forms which Local Government Boards send out. Many diseases are entirely omitted in the schedule, and the provision for specifying the respective ages at which death occurs in children has also been left out. He himself furnishes the most minute and complete accounts on a plan of his own, which is simply perfect. He adopts the form of tabulated squares based on the system in which temperature and meteorological returns are given. The perpendicular columns represents the number of weeks in the year, the side-figures numbers; by means of a line, therefore, drawn week by week, the rate of mortality can be readily seen for any week in the year, the resulting diagram showing at a glance the fluctuations of the death-rate at any period of the year. No trouble or expense has been spared in any way in getting up the most complete form of report which we have yet seen. An index is the only requirement. Dr. Griffiths is to be congratulated on the success of his work.

A MEDICAL OFFICER OF HEALTH.—The publication of your letter in these columns might be open to misinterpretation.

POOR-LAW MEDICAL APPOINTMENTS.

MACBRIDE, Charles, M.D., appointed Medical Officer and Public Vaccinator for the Parish of Kirkcubbin, Wigtownshire, *vice* W. Cumming, M.D., deceased.
MAHON, Charles J., L.R.C.P.I., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Easkey Dispensary District, Upper Division, of the Drogheda West Union.

APPOINTMENTS OF CONSULTING MEDICAL OFFICERS OF HEALTH IN IRELAND.

LYNCH, Francis J., M.D., appointed Consulting Sanitary Officer for the Loughrea Rural Sanitary District.
LYNE, Daniel John, L.R.C.P.Ed., appointed Consulting Sanitary Officer for the Castletown Rural Sanitary District.
MCDOWELL, Francis V., L.R.C.S.I., appointed Consulting Sanitary Officer for the Carlow Urban Sanitary District.
O'NEILL, Patrick, L.R.C.P.Ed., appointed Consulting Sanitary Officer for the Athy Rural Sanitary District.

OBITUARY.

FREDERICK BLUNDSTONE WHITE, M.D., M.R.C.P., F.L.S. DR. F. B. WHITE died at Tetbury, Gloucestershire, on February 4th, in his eighty-third year. Having finished his studies at St. George's Hospital, he became a member of the College of Surgeons, London, in 1813; soon afterwards, he passed the Army Medical Board, and was appointed to the 73rd Regiment, which he joined in Holland. He was present at the siege of Bergen-op-Zoom, March 8th, 1814, under General Sir T. Graham (afterwards Lord Lynedoch), when nearly all the British soldiers were cut to pieces or made prisoners, and volunteered to look after his men when prisoners—a post of no ordinary danger.

In 1815, the 73rd Regiment was ordered to join the Army in Belgium; and Dr. White was present at Quatre Bras and Waterloo, his regiment having but three officers not killed or wounded. After these engagements, he went with the Army to Paris. On coming home, the 2nd Battalion, to which he was attached, was disbanded, and, after four years' service, he went on half-pay. He married in 1820, and took to private practice at Nether Stowey in Somersetshire.

In 1827, he was offered the appointment of Surgeon in Ordinary to the late King, then Duke of Clarence, which he declined. In the same year, he moved to Tetbury, where his practice became large. In 1830, he became an Extra-Licentiate of the Royal College of Physicians of London; then M.D. of Giessen, and M.R.C.P. (exam.) in 1839. He was also Physician to Tetbury Dispensary, and a Fellow of the Linnæan Society.

Dr. White's keen perception, accurate diagnosis, and genial manner secured him the affectionate regard of all classes, and his opinion was much valued, even after his retirement from active work, in the two counties alluded to. He returned only last autumn to Tetbury, the scene of his former labours, to pass peacefully away in a ripe old age.

R. T. C. SCOTT, L.R.C.S. Ed., MELBY.

MR. SCOTT, who died lately, was born on January 1st, 1812. He studied at Marischal College, Aberdeen; and having then attended the medical curriculum in the University of Edinburgh, obtained the license of the Edinburgh College of Surgeons, at the early age of nineteen. He entered the navy as assistant-surgeon in 1833, and retired from the service as Deputy Inspector-General of Hospitals and Fleets in 1870. Amongst the honours conferred upon him were Sir G. Blane's gold medal for a medical history of the Burmese War in 1852, while serving in H.M.S. *Hastings*; the silver medal of the H.E.I.C. for the same war, the Baltic medal, the medal of the Royal Polytechnic Society of Cornwall, for Natural History; and his medical and surgical notes in the Royal Dockyard are printed in the Parliamentary Blue Book, 1869. His public complaint in the medical journals, of having been ordered to use the stomach-pump as a punishment, led to an Admiralty Order for the immediate abolition of the practice, though, at the time, his friends expected that he would be tried by a court-martial, and dismissed the service, for what they considered an act of madness. On his retiring from the medical superintendence of the Sheerness Dockyard, a splendid testimonial was presented to him by the workmen; and on his arrival in Shetland, a public dinner in honour of him was given at Walls. In 1850, he succeeded to the Melby estates. For many years after his succession the rental was expended in building improved dwellings and in making other improvements. The funeral took place in the churchyard of Sandness, on January 12th, and, notwithstanding the inclemency of the weather, was attended by about two hundred of his tenantry and friends from various parts of Shetland, with whom Mr. Scott's name was a familiar and loved household word, and by whom his memory will be cherished as that of a just, generous, broad-minded man.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examinations in the science and practice of medicine, and received certificates to practise, on Thursday, February 25th, 1875.

Evans, Frederick William, Crookherbtown, Cardiff
Kyngdon, Frederick Henry, Croydon, Surrey
Miller, Frederic Daniell, Streatham, Surrey

The following gentlemen also on the same day passed their primary professional examination.

Bass, Charles William, University College
Richards, Thomas, Guy's Hospital
Wilson, George, Charing Cross Hospital

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examination, held on Tuesday, Wednesday, and Thursday, February 9th, 10th, and 11th, 1875, the License to Practise Medicine was granted to—

Barnes, Raglan Wyckham	Hoops, Samuel Evans
Foyd, Thomas	Jones, Richard Sorton
Browning, John Norris	Jones, Wilmot John
Callanan, Michael	Sigerson, George
Curtin, Patrick	

The License to Practise Midwifery was obtained by—

Barnes, Raglan Wyckham	Hoops, Samuel Evans
Browning, John Norris	Jones, Richard Sorton
Callanan, Michael	Jones, Wilmot John
Curtin, Patrick	Pollen, Henry

MEDICAL VACANCIES.

THE following vacancies are announced:—

BECKETT HOSPITAL AND DISPENSARY, Barnsley—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.
BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.
BRISTOL LUNATIC ASYLUM—Assistant Medical Superintendent.
CLINICAL HOSPITAL AND DISPENSARY FOR CHILDREN, Manchester—House-Surgeon. Salary, £60 per annum, with board and residence. Applications to be made on or before March 1th.
COVENTRY AND WARWICKSHIRE HOSPITAL—House-Surgeon and Dispenser. Salary, £100 per annum, with board, lodging, and attendance. Applications to be made on or before March 25th.
DIVON AND EXETER HOSPITAL—House-Surgeon. Salary, £150 per annum, with board.
DORSET COUNTY HOSPITAL—House-Surgeon. Salary, £70 per annum, with £10 additional as Secretary. Applications to be made on or before March 18th.
DOVER UNION—Medical Officer for the St. Mary's District and the Workhouse. Salary, £120 per annum.
DURHAM COUNTY ASYLUM—Assistant Medical Officer.
HAILESHAM UNION—Medical Officer and Public Vaccinator for the Parish of Heathfield. Salary, £44 per annum, and fees. Applications to be made on or before March 8th.

KILBURN DISPENSARY—Senior Resident Medical Officer. Salary, £120 per annum, with apartments, coals, gas, and attendance. Applications to be made on or before March 8th—Assistant Resident Medical Officer. Salary, £80 per annum, with apartments.
KINGSTON, Jamaica—Two Medical Officers for the Public Hospital.
LEOMINSTER UNION—Medical Officer for No. 2 District. Salary, £90 per annum, and vaccination fees. Applications to be sent in on or before the 11th instant.
LONDON FEVER HOSPITAL—Resident Medical Officer. Salary, £200 per annum, with residence, coals, gas, and attendance. Applications to be made on or before March 6th.
MANSFIELD UNION—Medical Officer for the First District, and the Workhouse. Salary, £50 and £40 per annum, respectively.
MILFORD UNION, co. Donegal—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.
NEWMARKET UNION—Medical Officer and Public Vaccinator for the Third District. Salary, £45 per annum, and fees. Applications to be made on or before March 8th.
QUEEN'S HOSPITAL, Birmingham—House-Surgeon. Salary, £50 per annum, with board, lodging, and washing. Applications to be sent in on before March 11th.
ROYAL EDINBURGH ASYLUM—Assistant-Physician.
ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road—Physician.
SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.
SOUTHPORT INFIRMARY AND LOCAL DISPENSARY—Resident House-Surgeon. Salary, £100 per annum, with board, furnished apartments, coals, gas, and attendance. Applications to be made on or before the 8th instant.
ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.
ST. THOMAS'S HOSPITAL—Assistant Obstetric Physician.
SOUTH ESSEX DISPENSARY—Surgeon.
TORBAY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.
UNIVERSITY COLLEGE, London—Curator of the Museums of Anatomy and Comparative Anatomy. Salary, £200 per annum. Applications to be sent in on or before March 6th.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

ALEXANDER, John, M.B., appointed House-Surgeon to the Paisley Infirmary, *vice* W. Adams, M.B., resigned.
ELDER, George, M.B., appointed Surgeon to the Police, Nottingham, *vice* H. Taylor, M.R.C.S., J.P., resigned.
FOOT, Robert H., M.D., appointed Assistant Medical Superintendent to the Fife and Kinross District Lunatic Asylum, *vice* G. H. Mackenzie, M.B., resigned.
HALLOWES, Adolphus H. B., M.R.C.S. Eng., appointed Surgeon to the West Kent General Hospital, Maidstone, *vice* W. Hoar, M.R.C.S. Eng., resigned.
JOHNSON, John, M.D., appointed Physician to the Tunbridge Wells Infirmary.
KAIKKEE, Paul O., M.R.C.S. Eng., appointed Accoucheur to the Torquay Lying-in Charity, *vice* W. B. Harland, Esq., deceased.
KENNEDY, Henry, M.B., appointed Physician to Simpson's Hospital, Dublin, *vice* R. Law, M.D., resigned.
LAWRENCE, Alfred E. A., M.D., appointed Physician-Accoucheur to the Bristol General Hospital, *vice* J. G. Swayne, M.D., resigned.
LYON, James G., M.D., appointed Dispensary Surgeon to the Western Infirmary, Glasgow.
*SWAYNE, Joseph G., M.D., appointed Consulting Physician-Accoucheur to the Bristol General Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

SOLOMAN.—On February 24th, the wife of Charles Solomon, L.R.C.P. & S. Edin., Kirklaugh, of a son.

MARRIAGE.

DUNCANSON—BAIRD.—At Edinburgh, on February 24th, by the Rev. Mr. Mac-knight, F. C. Whitburn, uncle of the bride, J. J. Kirk Duncanson, M.D., to Isabella, eldest surviving daughter of the late Robert Baird, Esq., of Limerigg. No cards.

BEQUESTS.—The late Mr. Alfred Wigan, in addition to other charitable bequests, left to the Home for Incurables, West Hill, Putney Heath; St. Mary's Hospital, Paddington; and the British Orphan Asylum, Slough, £500 each. All the legacies are given duty free.—Mr. William Willicombe of Tunbridge Wells has left £100 for the use of the Infirmary of that town.—Dame Sarah Haberfield (widow of Sir John Kerle Haberfield, who was six times Mayor of Bristol) has bequeathed to the Bristol Royal Infirmary £5,000, to be invested in consols, and the annual income applied for the maintenance and support of one of the existing wards, to be called Lady Haberfield ward; to the Bristol General Hospital, £1,000, to be invested in consols, and the annual income applied as a yearly prize, to be known as Lady Haberfield's prize, for the pupil at the hospital who shall exhibit the greatest proficiency; the Blind Asylum, and the Deaf and Dumb Institution, Bristol, and the Hospital for Sick Children, Clifton, £100 each; to the Clifton Dispensary, £50. There are numerous other legacies of a charitable nature, all of which are directed to be paid free of duty.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopedic, 2 P.M.

WEDNESDAY ...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London. Anniversary Meeting (102nd).

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Wm. Miller Ord, "On Urinary Crystals and Calculi, the Circumstances determining their Form and Production".

WEDNESDAY.—Epidemiological Society, 8 P.M. "On Arithmetical Questions involved in the Rise and Progress of Epidemics", by George H. Evans, M.A., M.D. Cantab.—Hunterian Society. Council Meeting, 7.30 P.M. General Meeting, 8 P.M. Mr. De Berdt Hovell will introduce a discussion on "Ventilation in Relation to the Treatment of Scarlatina".

FRIDAY.—Clinical Society of London, 8.30 P.M. Dr. T. T. Whipple, "Fatal Pleuropneumonia in an Opium-eater"; Mr. C. Burwell, "Case of Acute Necrosis in which the whole Shaft of the Ulna was removed"; Dr. Thomas Dowse, "Unusual Case of Lead-poisoning".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

J. C. will observe that his query is answered in another part of the JOURNAL.

MR. SCOFIELD's suggestion is one which, we think, might be adopted with advantage. The matter shall be looked into.

THE CONTAGIOUS DISEASES ACTS.

WE are requested to correct a misapprehension on the part of Dr. Wm. Carter, in stating that the "five members of the Liverpool Royal Infirmary School of Medicine who did not sign the memorial constitute more than one-third of the entire staff". The school staff numbers seventeen, and of the five non-contents three are not medical practitioners, and therefore were not asked to sign.

QUININE FRAUDS.

AN instance of importing spurious quinine, says the *North China Herald*, came lately under the notice of the Customs authorities, the quantity being 100 ounce bottles, for a Chinese firm, we believe. The shipment was detained on the score of false declaration, and a bottle submitted to Messrs. Watson, Cleave & Co. for chemical analysis. It was suspected that the substance was salicine, but the application of the usual test failed to indicate any trace of salicine in the sample. Quinine itself, or any of its salts, was equally undistinguishable, and subsequent examinations proved the substance to be composed entirely of muriate of cinchonine, a product of cinchona bark, the market value of which is one-fourth that of quinine, while it possesses remedial qualities analogous but less in degree to those of the valuable medicine for which it is attempted to pass it off. The bottles bear a neat label, flanked by exhibition medals, on which the inscriptions are not quite correctly printed. The label runs: "Sulfate de Quinine de Pelletier, Delondre et Lévaillant; 1 once Anglé; Amet De Lisle et Cie, Successeurs; Paris Rue Malher 18." The question of checking the attempts made to cheat the public into buying a spurious or inferior preparation of a febrifuge is of great importance in a place like Shanghai, and we hope will receive the attention of the authorities. It might do some good, meanwhile, if the native press were to draw attention to this "lie" quinine.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

HOSPITAL SATURDAY.

SIR,—I beg you will oblige the retiring Hospital Saturday Council by permitting me to mention that, except in three instances, £4,521 15s. 10½d. of the first Hospital Saturday collection has been paid to those Hospitals and Dispensaries, the Committees of which returned on the Council's forms particulars as to the amount of "Relief," "Economy," and "Efficiency" in their respective institutions. The distribution was made under these heads, and upon a plan which obviated the possibility of partiality. In many instances, patients' letters, *pro rata* to the amount allotted, have been returned. In others, notably that of the French Hospital, intimation has been given that all persons recommended by the Council will be received as patients without restriction. The Council will issue the letters to local and auxiliary Hospital Saturday Committees, and to *employés* of firms, on application, *pro rata* to the amount collected in each case. Letters not so apportioned the Council will issue individually to deserving persons.

I beg you will also permit me to mention that the Hospital Saturday Board of Delegates will meet on Saturday, the 27th of March next, to elect the Council who will organise the collection for this year (1875) in accordance with the resolution passed by the retiring members, to further ensure that the working classes shall have that voice in the management of the movement which will ensure its future success. The Board of Delegates will consist of members elected thereto by Lodges, Courts, and branches of the various Friendly and Trade Societies, and *employés* (100 or upwards) of firms. The Board will meet at least once in every three months to receive reports from the Council, over whose proceedings they will maintain a general supervision. A copy of the resolution as to the election of delegates, and the form of certificate, may be had on application to the retiring Council.—I am, etc.,

CHARLES MERCIER, Chairman.

Council Rooms, 28, Leicester Square, Feb. 20th, 1875.

H. M. STATISTICAL SOCIETY.—The bills of mortality were commenced so long ago as 1592, by the Parish Clerks' Company, who about 1625 were licensed by the Star Chamber to keep a printing press in their hall for printing the bills. The weekly bills of the parish clerks have, however, been superseded by the "Table of Mortality in the Metropolis," issued from the Registrar General's Office since July 1, 1837.

UNREGISTERED PRACTITIONERS.

DR. T. ORME DUDFIELD, in his monthly report on the Health of Kensington, raises the following questions, on two of the deaths registered in the Town sub-district which were "not certified", *i.e.*, the deceased were attended in their last illnesses by unregistered practitioners, whose certificates were accepted only as informal evidence of the nature of the fatal disease, the deaths being returned by the Registrar as "not certified", in accordance with the instructions of the Registrar-General. Under the Registration of Births, etc., Act, a duly registered medical practitioner is required to give a certificate, setting out the cause of death of any person who may have been attended by him. This is the certificate which was given in the cases above referred by unqualified practitioners, one of whom is the person against whom your Vestry directed proceedings to be taken some months ago for alleged contravention of the "Medical Registration Act". By the 37th section of that Act, the certificate he gave in the case now alluded to, is declared to be not "valid," because he is not registered. But if he had been duly registered, and had refused to give the certificate in question, such refusal would have entailed a penalty under the new Act. Whether his certificate brings him within the penal clause of the Medical Act, for the offence of "falsely pretending to be registered under the Act," is a nice question of law, which Dr. Dudfield states that he is incompetent to answer.

BIBLIOPOLE.—The total expense of the Library of the College of Surgeons, including purchases, binding of books, salary and wages was, according to the last calendar, July, £659 ss. 6d.

ETIOLOGY OF PUERPERAL FEVER.

SIR,—I have read attentively the article on the above subject in this week's JOURNAL, and must take exception to some of the statements therein made.

The first is, that I consider the writer bases his suggestion of the contagion of puerperal fever being connected with his own person in his cases of contagion, on very insufficient data, for the following reasons. Since writing my former letter to you I have unfortunately had another case prove fatal in my practice. Now, as three months have elapsed since my former case, I do not suppose any one can be by any means connect this last case with my former one, as I have attended my cases since then; and yet if I had ceased practice for a period of three months and then resumed it, and met with a fatal case soon after doing so, by reasoning as your correspondent has done I should have come to the conclusion that these months were insufficient to eradicate this contagion from my person.

By expressing himself willing to attend cases of puerperal fever, one would suppose he did not believe in the contagion theory at all.

By his inability to discover any symptoms of ill health in himself. As, if a man in bad health is more liable to transmit the contagion than a healthy man, which I suppose is possible, he would be almost certain to be attacked with some disease of a nature akin to puerperal; and yet your correspondent does not speak of his having suffered from either erysipelas, scarlet fever, sore throat, etc.

Secondly, I fail to see on what grounds he concludes that there are three different kinds of puerperal fever. I presume in making his divisions he had more in mind the different ways in which the disease arises. As I do not for a moment believe that the disease given by contagion differs from that arising either from causes which have to do with the patient alone, or from the epidemic form.

It seems to be a fact that how puerperal fever arises in a man's practice is unknown, and also that when, unfortunately, a fatal case does occur, it is clearly the duty of the surgeon to abstain from attending any more confinements for a few weeks. Hoping that these letters, and the case of the Coventry midwife, will awaken attention to this subject,—I am, Sir, yours truly,

J. MASON.

BITING OF THE NAILS.

SIR,—Can any of your correspondents suggest a good method of combating this habit in children, or briefly state what treatment has been found most efficacious?

G. Y.

M. KENSINGTON.—Archdeacon Pott was his son. Percival Pott was forty-two years Surgeon to St. Bartholomew's Hospital. He died December 22nd, 1788, aged 75 years, and was buried in the church of St. Mary Aldemary, Bow Lane, Cheap-side.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

MEDICAL DEGREES AND TITLES.

SIR.—The requirement of residence at an University prior to admission to examination for its degrees entails the perpetuation of a system which identifies the teaching and examining bodies, the error of which appears to have been recognised by the founders of that excellent institution, the University of London. It will scarcely be assumed that the gentleman who passes a year at either Aberdeen, St. Andrew's, or Galway, is more advantaged thereby than one who passes the same period of time in London, or in one of our large manufacturing towns. The requirements of the University of London, excellent though they be in intention, are undoubtedly, to a certain extent, prohibitory; frankly, I dared never affront them, and I have known many men who have given proofs of some capacity stop short in this difficult upward career. Some continental Universities, untrammelled by tradition, and rather in appreciation of practical results, do admit to the degree of Doctor by examination without residence. At Brussels, the examination I passed may have been inferior by the absence of written proofs of capacity, but I have no hesitation in saying was superior, practically, to our examinations at home, especially in the item of practical surgery, in which three operations have to be performed on the dead subject. This is an improvement which, it is to be hoped, may be adopted by our College of Surgeons in their Membership as well as in their Fellowship examinations, that it may be able to ascertain that it is really providing the public with surgeons who know where they are going when they have a knife in their hands.

The assumption of the title of Dr. by Licentiates of a Medical College is to be deprecated: either there is a distinction and a difference between a degree and a diploma, or there is not; and it is difficult to understand how, logically, the King and Queen's College of Physicians in Ireland can give a license conferring the right (as stated in black and white, and in large characters, on the diploma) to use the title of "Doctor in Medicine."—I am, sir, your obedient servant,
W. N. HIRON, M.D. Brussels, L.R.C.P. Lond., M.R.C.S.E.

SIR.—The numerous letters in your *JOURNAL* on the subject of medical titles show the interest taken on the subject. I believe that the dissatisfaction in the profession arises from the fact, that so many men, neither of superior ability or of education, get into practice with M.D. tacked to their names, and are thus placed before the public in a position above their fellows. Are the opportunities for medical education at Aberdeen, Glasgow, St. Andrew's, Oxford, and Cambridge, greater than at the London hospitals—St. Bartholomew's, Guy's, the London, etc.? Who are the teachers and examiners at the former places?—men hardly known out of their provincial towns, certainly not out of Scotland. In London, the opportunities are greater, the hospitals larger, the teachers and examiners many, of European reputation; but a student who passes the examining boards of the London College of Physicians, the College of Surgeons, or the Apothecaries' Company, is without a title, a plain "Mr.": he is even snubbed by the College of Physicians for styling himself "Dr." Does Scotch influence prevail at the London College? The upper and middle classes are finding out by comparison, that the title of Dr. or M.D. under the present régime by no means implies superiority of the man or his education.

Hoping that some means will be found, even if it require an Act of Parliament, for giving a London medical title to those passing the London examinations, and rectifying the present anomaly in respect of medical titles, I remain, sir, your obedient servant,
W. M.

SIR.—As one of the numerous M.s and L.R.C.P.s of Edinburgh, I beg to express my gratitude to you for your powerful advocacy of the cause of those amongst us who desire to be admitted by some British University to examination, without residence, for the degree of M.D.; but I beg respectfully to point out that your recommendation that only those who have gone through a full curriculum, extending over at least four winter sessions, be admitted to examination, would, if adopted, virtually exclude four-fifths of the L.R.C.P.s, who, like myself, only completed in their student-days three winter and two summer sessions, and who, being now in full practice, could not spare time to complete the extended curriculum.

With regard to the much disputed title of "Dr.", I beg to say that, so long ago as I can remember my age is forty-six, all Licentiates and extra-Licentiates of the College of Physicians of London were indiscriminately accorded the title of "Dr." by their professional brethren, and had that title engraved on their cards and door-plates; and when, in 1850, I passed my examination at the College of Physicians of Edinburgh, I thought myself fully justified in adopting the title of "Dr.", and have continued to do so ever since, though of course I never wrote M.D. after my name, nor allowed my friends and patients to do so. I may add that the College of Physicians of Edinburgh, when sending me the annual list of Fellows, Members, and Licentiates, always addresses me as "Dr."

I enclose my card, and am, sir, your obedient servant,
M.R.C.P. Ed.

SIR.—As a constant reader of your valuable *JOURNAL*, I have perused with interest the numerous letters published in your columns on the above subject, and I should like to add my mite to the collection. Into the question of the right of L.R.C.P.s, etc., to the title of "Dr.", I do not intend to enter, my object being merely to suggest means whereby the acquisition of the title M.D. might be facilitated without lowering the standard of professional knowledge now required for its attainment.

There is at present no University in the United Kingdom from which the degree of M.D. can be obtained without residence or its equivalent. I speak advisedly, though I know I shall be met by the statement that the University of London requires no residence of its graduates. But it requires its equivalent; that is to say, the time four or five years spent in medical study must be so spent at a recognised medical school after matriculation. It is in these two last words that the rub exists. By all means, require study at recognised medical schools, but I do not see why that study need necessarily be after matriculation. If evidence were required that the student had passed a sufficient time at recognised places of education, that should be sufficient to admit him to examination for degrees, whether he matriculated before or after commencing professional work. There are many men who, on entering on their student-career, do not think of taking a degree; but, after two or three years of study, they find themselves drawn strongly to the practice of physic *par et simple*, and wish to take the M.D. degree, and thus qualify themselves for hospital appointments and consulting practice. But they knock at the portals of Burlington House in vain.

They did not matriculate before entering on hospital work; and therefore, if they want a degree, they must matriculate now, and go through their two or three years again. This is surely a hard case; but I am convinced it is the condition of many students at the present time. Therefore, I would suggest to the Senate of the University of London (which, being the metropolitan seat of learning, should lead the way in all liberal and salutary reforms) to do away with the regulation which requires matriculation previous to the commencement of professional study, and to take so many years of work at a recognised medical school as sufficient qualification for admission to its degrees—after stringent and searching examination, of course. If the University of London will not relax thus far, the University of Durham, which already allows residence at Newcastle-on-Tyne to count as residence in the University itself, might surely extend its boundaries, and allow study at any recognised medical school to count as residence; and then permit students from all parts of the kingdom to graduate at Durham. These facilities for graduation would in no way detract from the value of the degree, as the standard of professional knowledge requisite for its attainment might still be kept sufficiently high to uphold the dignity of the M.D., and to stamp the bearer of the title as a man of high professional knowledge and scientific culture.

Trusting I have not run to too great length, and hoping you may think my suggestions worthy of insertion, I enclose my card, and remain yours obediently,
A KING'S MAN.

THE INFLUENCE OF TEMPERATURE DURING CHILDBIRTH.

SIR.—Painless and bloodless surgery is now universally practised and admired. Painless and bloodless midwifery—although a matter of at least equal importance—is not only not universally practised, but, I will venture to say (except in the use of anaesthetics), is a subject not even understood. I have endeavoured to show, in my previous letters, how simply, and by the regulation of temperature, and without the aid of any anæsthetic medication whatever, the pangs of childbirth may be reduced to a minimum, both as regards time and intensity. By the same principle of treatment, essentially chrono-thermal, I have suggested a means which, if fairly tried, will, I am firmly convinced, banish for ever that opprobrium medicorum—*post-partum* hæmorrhage. For such purpose, it will undoubtedly be found most desirable to apply the remedy, the *graduated cold douche*, by way of anticipation, speedily after the birth of the child, and before the separation of the placenta.

Apparently, in contradiction to what I have written, but, in reality, strongly in confirmation of it, comes the latest suggestion from New York, namely, the use of vaginal injections of warm water (at 100 Fahr.), as a means of arresting uterine hæmorrhage. This is a step in the right direction, and will do more than anything else to revolutionise all previously accepted ideas on the subject.

Everywhere, and for ages past, has been taught the utterly fallacious doctrine that cold—*quoad* cold—arrests hæmorrhage; and nothing but disaster has resulted when, in accordance with such teaching, the prolonged use of cold has been consistently carried out; for only in so far as cold, by reaction, is capable of restoring the natural warmth of the body, can it, by any possibility, restore the healthy tone of ruptured vessels, or indeed of anything else. Hence cold, properly applied, with the view of obtaining such reaction, is most valuable as a means of preventing hæmorrhage, but is a measure of doubtful utility in proportion to the amount of hæmorrhage which has already occurred, and the consequent difficulty experienced by the patient in acquiring the necessary reaction; and it is precisely at this most critical and important juncture that warm vaginal injections (at 100 Fahr.) may be brought into play with the most striking effect.—I am, etc.,
Harlesdon.

M.D.

THE CROONIAN LECTURES ON ADDISON'S DISEASE.

Delivered at the Royal College of Physicians, London.

By E. HEADLAM GREENHOW, M.D., F.R.C.P., F.R.S.,
Physician to and Lecturer on Medicine at the Middlesex Hospital.

LECTURE I.—(Concluded.)

BEFORE quitting the description of the constitutional symptoms and discoloration of the skin, I must advert to one remarkable feature common to them both, to which I directed attention in my clinical lectures on the subject in 1866. It has been noted also by several other observers in the reports of typical cases; but, owing no doubt to the shortness of the time that the majority of patients have remained under treatment, it has never hitherto been classed in its true place as one of the characteristic features of the disease. I mean its paroxysmal mode of progress. The asthenia, the constitutional symptoms generally, the change of colour in the skin, are all, it is true, progressive, but not steadily so. The course of the disease, on the whole, is slow and chronic; but it is subject to alternate exacerbations and remissions, usually dependent in some degree upon favourable and unfavourable circumstances, but sometimes also apparently independent of them. During the remissions, strength is in a great degree recovered, appetite is improved, sickness is abated, the discoloration pales; and, above all, the patient's whole aspect betokens that a heavy weight has been lifted from his head. After each fresh exacerbation, however, the patient remains upon a lower level than during the previous remission; the recovery of strength and the abatement of the other symptoms are less marked; the skin, though paler than during the last exacerbation, is visibly darker than before it. The alternations may occur several times before the onset of the fatal paroxysm; but, on each occasion, the patient takes one downward step that he never regains. In the case of two of my own patients, these alternations were well marked, though they died in one and two years respectively after they came under my care; and in the case of two others, who were under my care five and eight years respectively, the remissions in the symptoms and the paling of the discoloration were most striking. Dr. van den Corput relates, in the case of a woman aged thirty, who died under his care in St. John's Hospital at Brussels, that during four years she had three considerable periods of remission, and that the colour regularly alternated with the symptoms. Dr. Severini records that a woman, who was under his care for some months in the Hospital at Bologna, had, before her death, several alternations of health; and that the discoloration of the skin was darker or lighter, according to her state. Drs. Löwe and Wolff have noted similar alternations in two characteristic cases. Dr. Ringer also states, in the report of a case sent to me for exhibition to the Pathological Society in 1873, that with each slight improvement the discoloration of the skin grew less, but in each relapse it became darker than before.

But although slow chronic progress, with alternate exacerbations and remissions, is the usual course of the disease, it is by no means the only one. In many cases, especially in young subjects, the disease runs what may be termed a latent course; that is, the constitutional symptoms first appear suddenly in a fully developed form, producing death in a few days. This occurred in the case of Dr. Seth Thompson's patient, a man aged 20, who, although the skin was becoming dusky for six weeks, had exhibited no symptoms of illness until two days before admission into the hospital, and grew worse so rapidly that he died on the following day. The girl, E. W., who died under my care in 1865, is another illustration of this occasionally latent course of the disease. She returned home after an absence of six weeks in the country, apparently quite well, though her parents said she seemed rather sunburnt. This dinginess of complexion never left her; but she remained well for some months. Her father then regarded her as drooping for three or four weeks, but she had no symptoms of illness. She attended school until two days before her admission to the hospital, when she presented all the constitutional symptoms of disease in so fully developed a form that I diagnosed the case at first sight, although the discoloration was scarcely observable. She had suddenly become sick and cold; and, notwithstanding all possible restoratives, she died in a week. Dr. Schotte relates almost a parallel case of a girl, aged 15. She had been doing heavy work in the country, and complained for about four weeks of debility and powerlessness of limbs, and a tendency to fall asleep. She was admitted into hospital with symptoms of the disease in an advanced stage, and died the same night. Without doubt, these differences in the mode of onset and course of the disease are

partly due to differences in the mode of progress of the suprarenal lesion. The suddenly fatal termination in the first paroxysm is, however, like the accession of successive paroxysms, partly due also to some depressing external influence. In the case of my little patient, this was apparently an aperient administered by the mother, and in Dr. Schotte's case, a dose of calomel and jalap given in the hospital.

One other peculiarity in the course of the disease must not be overlooked—the very variable date of the appearance of bronzing of the skin, as compared with that of the constitutional symptoms. In a large proportion of cases, as might be expected in a disease prevailing chiefly among a class of persons who become hospital patients, no notice has been taken of this point; and in a great many other cases it is reported that the appearance of the constitutional symptoms and of the discoloration of the skin were simultaneous, or nearly so. Sometimes the discoloration is mentioned as soon following the characteristic symptoms, and sometimes as slightly preceding them. But in a certain number of cases, chiefly among the few that have occurred in the middle and higher classes, or have been longer than usual under observation, the interval between the appearance of the constitutional symptoms and that of the bronzing of the skin has been more accurately recorded. In a typical case recorded by Dr. Addison and Dr. Wilks, the patient, a young lady, aged 18, was ill only four months; but the bronzing had existed a year. In a case of Mr. Jonathan Hutchinson's, the patient, a boy aged 11, felt ill only a few weeks; but the bronzing had been noticed for six months. (I omit for want of time other illustrations of the same point.) These were all typical cases of the disease, no lesion being found of the slightest importance except that of the suprarenal capsules. Again, in about an equal number of cases of the same class, the development of the constitutional symptoms is recorded as having preceded the discoloration of the skin by several months, and sometimes by even a longer period of time. In a typical case related by Mr. John Moore, the patient, a clerk, had been in failing health for two years with the characteristic symptoms of the disease; but the discoloration only became visible during the last six months. In a case of Dr. Spender's, the patient, a young woman aged 21, was ill for a year with fully developed typical symptoms; but the discoloration only began to make its appearance three months before death. Dr. Robertson relates the case of a labourer who suffered from the characteristic symptoms of the disease twenty-two months, never having had any previous illness, but in whom the bronzing of the skin only began on the face, arms, hands, and chest, a year before death. (I must omit some other striking examples.)

I now turn to the consideration of the pathological lesion which Dr. Addison's observation of the clinical phenomena he described led him to seek for as necessary to explain them, and which he only briefly mentions as a diseased condition of the suprarenal capsules. He evidently believed that any diseased condition of these organs might produce the same effects; for he recorded in his monograph, in connection with the spurious cases to which I have referred, other diseased conditions of the suprarenal capsules totally different from the particular diseased condition which he had found in his own cases. This particular condition is nevertheless well described, as regards its naked appearance, in the report on the *post mortem* examination of one of his most typical cases. Each suprarenal capsule, he records, was completely destroyed, and converted into a mass of stumous disease—the latter of all degrees of consistency. The left suprarenal capsule had formed at the upper part a close connection with the outer coat of the stomach. The upper part of this capsule seemed fluid, and of the colour of pus; the lower firm, and of the consistency of putty. The right capsule had all degrees of consistency from the bottom to the top; the lower part being almost fluid, resembling pus; the centre putty-like; and the top was quite earthy, separate angular pieces being easily detached. Dr. Addison, however, gives no description of the microscopical appearances in this case, nor in any other case except one which was submitted to Dr. Hodgkin for examination.

I shall now proceed to describe more fully the pathological changes in the suprarenal capsules, as I have observed them in careful *post mortem* examinations of the same typical cases from which I have drawn the clinical picture of the disease. The capsules are generally enlarged, hard, and nodulated, though in rare cases they are of normal or less than normal size. On section, they scarcely ever present any trace of the distinction between the cortex and the medulla, so obvious in the normal condition of the organs. In all the fresh specimens I have seen, the cut surfaces have presented a marbled appearance, from the mixture of two materials of different colour and consistency. One of these materials is a semitransparent tissue of firm consistency, and grey or greenish grey in colour, at least when fresh cut; but, on being exposed to the air, it assumes a pink hue. The other material is opaque yellow, or

cream-coloured, and it assumes the form of irregular roundish masses embedded in the translucent tissue, from which they can often be easily enucleated. (This drawing shows better than any other that I have been able to procure, the appearance of a capsule freshly cut. The fact that I have stated, that on exposure to the air the greyish translucent tissue becomes pink, renders it difficult to obtain good drawings of the capsules when fresh. This is a copy of the original drawing that Dr. Addison had made for his book. I exhibit also another drawing, a very peculiar one, of a case in which the capsule has already begun to turn pink. There are two other drawings: one of a case in a very advanced stage, when the capsule is shrinking and the parts become hard; and another showing the same condition as that represented in a previous drawing.)

On close examination, intermediate gradations will often be seen between the translucent parts and the opaque cheesy nodules, and sometimes cretaceous granules, or small masses formed by the hardening of the cheesy matter, are felt to grate under the knife. (There are specimens here illustrating all these changes.) More rarely, the whole of the cheesy material dries up and hardens into calcareous masses, and it is in these rare cases that the capsules are smallest. Not unfrequently, on the other hand, the caseous matter softens down into collections of creamy fluid, called abscesses by some observers, and is found to occupy the larger or smaller cavities in the diseased capsules. In some cases, the whole central part of the organ constitutes one large cavity filled with creamy fluid, but more commonly there are, if any, several small cavities, the fluid in which is of the same character, but of various degrees of thickness.

It follows obviously from this description, that the proportions of the translucent and opaque materials, found in the diseased capsules, differ greatly in different cases. In some few cases, the translucent substance constitutes nearly the whole of the mass; in others, the yellow friable matter greatly predominates; whilst in others the normal tissue is almost entirely replaced by calcareous masses or creamy fluid. All these gradations, however, depend solely upon the duration and the more or less acute or chronic course of the disease. The morbid process is identical in them all—a fact which, as Dr. Wilks pointed out, gives a greater definiteness to the disease than Dr. Addison himself conceived it to possess.

On microscopical examination, the translucent substance is seen to consist of a fibrillated stroma containing numerous lymphoid corpuscles. In some cases, these corpuscles are arranged in rows between bundles of fibres; in others, they are contained in a delicate reticular stroma. The opaque cheesy material is formed of amorphous granular matter mixed in variable proportions with irregularly shaped shrunken cells, nuclei, and oil. Dr. Sidney Coupland found, on a microscopical examination of the capsules in my last case, some masses corresponding with giant-cells, which Schuppel considers distinctive of tubercle. The creamy-looking fluid consists mainly of oily debris. It is evident from these microscopical appearances that the morbid process in the capsules consists primarily in their infiltration by an inflammatory exudation of low type, which first becomes converted into fibrous tissue destroying the normal structure of the organs, and finally undergoes caseous degeneration.

In every one of my own cases, and in many of those carefully examined and reported on by others, clear evidence of inflammation in the cellular envelopes of the capsules has been afforded by great proliferation of their connective tissue, and also by the existence of firm adhesions to the neighbouring organs, such as the diaphragm, liver, pancreas, vena cava, kidney or stomach. It is probable, therefore, that in many other cases these conditions have been overlooked or have remained unreported, their significance not being understood. Of course, such extensive overgrowth of connective tissue round the capsule, cannot fail to invest the nerves of both the suprarenal and the solar plexuses with dense indurated tissue; and accordingly, when these nerves have been examined, their fibrous investment has been found to be hypertrophied. The first careful dissection of the nerves in the neighbourhood of the capsules in a case of Addison's disease was made by Dr. Habershon, who had published in the *Guy's Hospital Reports* in 1856 a very valuable paper on the abdominal sympathetic and its connections with the phrenic and pneumogastric nerves. The results of the dissection of the nerves in the case to which I refer, were published in 1864 in the same series of reports. He found the semilunar ganglia, and the branches of the nerves proceeding to the capsules, surrounded by an unusual quantity of dense fibrous tissue. In several of my own cases, the same condition has been found, though they have not been dissected out of the mass of hard tissue in which they were imbedded. My colleague Dr. Cayley, several years ago, at my request, carefully examined the suprarenal nerves in the body of a man who died of Addison's disease in the Middlesex Hospital, under Dr. Stewart's care.

He found the nerves proceeding from the semilunar ganglia to the suprarenal capsules, and especially one branch of the great splanchnic, twice the size of the same nerves in a healthy subject dissected at the same time. A microscopical examination showed that the increased size was due to the increase of the fibrous investment of the nerve-bundles. Dr. Tuckwell of Oxford also made a complete dissection of the nerves in a case of Addison's disease, recorded by him in *St. Bartholomew's Hospital Reports* for 1873, in which case, as in two others that he had previously dissected, he found decided evidence of thickening, extending from the surface of the capsule to the suprarenal plexus, the semilunar ganglia, and thence up the great splanchnic nerve. The thickening of the nerves was found on examination to be caused by hypertrophy of their fibrous investment, and not by any apparent change in the nerve-fibres themselves. A similar condition of these nerve-plexuses in cases of Addison's disease has also been verified by several eminent foreign pathologists. Rindfleisch, in his report on the microscopical examination of the nerves in a case of Kuhlmann's, found two large nerve-trunks, the fibres of which were undergoing fatty degeneration, bound up in firm adhesions which attached the diseased capsules to neighbouring parts. Professor Tigri found the semilunar ganglia considerably enlarged, and the nerve-fibres forming the solar plexus thickened by hypertrophy of the neurilemma. Hertz also reports that he found the coeliac plexus, and particularly the semilunar ganglia, enclosed in hard connective tissue, with considerable thickening of the connective tissue sheaths of the nerve-fibres going off from the ganglia; and Wolff observed the nerves of the solar plexus and the semilunar ganglia enclosed in a thick envelope of connective tissue. Bartsch, Van Andel, and others have reported similar conditions of the nerves.

In almost every case I have seen, the dense connective tissue surrounding the capsules has contained some enlarged lymphatic glands, and the same circumstance has been frequently reported by others. The mesenteric and retroperitoneal glands in the neighbourhood of the capsules are also generally enlarged. On section, these enlarged glands sometimes present only the normal appearances, but more commonly they are firm, glistening, of a pale colour, and not unfrequently in process of caseation. Microscopic examination sometimes reveals no obvious change of structure; in other instances, the nerves have been hard and glistening. There is another morbid appearance which has been so frequently observed by myself and others in cases of Addison's disease, that I feel justified in ranking it among the characteristic, though not, perhaps, quite invariable lesions incident to the disease: I mean enlargement of the solitary glands of the small intestine, sometimes likewise of the large intestine. In many cases also the mucous membrane of the stomach, especially towards the pylorus, has presented a mammillated appearance, and the mucous surface has not unfrequently been covered with tenacious grey mucus. Small ecchymoses, and more rarely superficial abrasions or small ulcers, are also found on the mucous membrane of the stomach, and in a few instances on that of the large intestines. Careful microscopic examination of the mucous membrane of the stomach in two different cases by Dr. Sidney Coupland and Mr. Schäfer have shown that the mammillations are caused by overgrowth of lymphoid tissue. Some of these mammillations presented small depressions in their centres, which were ascertained by Mr. Schäfer to be due to a breaking down and opening into the surface of the summits of the patches. Probably these depressions indicate the first stage of the small ulcers which have been reported by other observers as occurring in the gastric mucous membrane.

Lastly, I must not omit to mention one other morbid organic change too often recorded in cases of this disease to be passed over here, although I have had no personal experience of its presence. In a very considerable number of genuine cases, including cases reported by Dr. Addison and Dr. Habershon, the spleen has been found to be enlarged, sometimes greatly enlarged, and usually also dark coloured and soft. It is worthy of remark that in very few of these cases have the patients, so far as is known, suffered from intermittent fever. There has, however, been no enlargement of the spleen in any of the cases which have been under my own care. It is, therefore, quite certain that the disease may run its most typical course without presenting this lesion, and that consequently an enlarged spleen, though undoubtedly an occasional, is by no means an essential feature in the morbid anatomy of Addison's disease.

Having thus delineated, as I believe, the true clinical and pathological features of Addison's disease, I must, in conclusion, observe, to prevent misunderstanding, that it is only in a certain number even of the typical cases that the striking clinical phenomena which I have described are all fully developed. The progressive asthenia, muscular debility, feeble circulation, and low temperature, are invariably present; and in my experience neither loss of appetite, nor vomiting nor dyspnoea,

nor faintness on exertion, has ever been absent in the later stages of the disease. But there is not perhaps one of the other peculiar symptoms which is invariably observed. Every physician is sufficiently aware that this is equally true with respect to every other organic disease. It is only in the comparatively small number of cases in which an organic disease runs a long uncomplicated chronic course, that we can look for the full development of all its peculiar symptoms. The absence of some of these, therefore, in complicated cases, or in cases of short duration, cannot be regarded in Addison's disease, more than in any other organic disease, as militating against the connection between such symptoms and the pathological conditions with which they are associated.

THE GOULSTONIAN LECTURES ON PUERPERAL FEVER.

Delivered at the Royal College of Physicians, London.

By ROBERT J. LEE, M.D., F.R.C.P.,

Assistant Physician at the Hospital for Sick Children, Great Ormond Street.

LECTURE II.—(Concluded.)

THE interval between Gordon and Semmelweis of half a century was occupied chiefly by those important investigations into morbid anatomy and pathology, both general and microscopical, which have contributed to the improvement of every department of our profession, and particularly to the practical knowledge of diagnosis and etiology. It is to this source that we must look for modifications in general opinion concerning some of the phenomena of puerperal fever; and it will be, I think, most convenient to defer our inquiry into the value of Semmelweis's observations till we have reviewed the progress of pathological research. The real reason why there was such a universal movement in that direction about the end of last century may be easily traced to a few powerful minds, like the two Hunters and those nearly associated with them, who clearly perceived that the pathological study of the effects of disease promised more than the study of symptoms.

The result of this method, as far as it influenced the subject of puerperal fever, was the introduction of several new terms into our nosology which were intended to describe the pathological conditions of different organs, structures, and tissues. Thus originated puerperal peritonitis, phlebitis, metritis, and some others. These terms, as we know, did not include any explanation of the remote cause which induced the changes observed by the pathologist. They all more or less involved the assumption, that what is termed inflammation was their exciting cause, and the practical object of these terms was to connect local inflammatory processes with local and constitutional symptoms.

The subject of the pathology of puerperal fever is an extensive one, and I shall not attempt to treat it in the same manner as that of the etiology of the disease. There may be some excuse for doing this, as I feel more equal to deal with this part from personal experience and observation than with the other, which we have regarded as a matter of history. There is one point which would not be difficult to prove, if it were not self-evident, and that is the fact, that neither morbid anatomy nor pathology assisted the theory of Gordon: I mean to say, that the idea of a specific poison would never have been evolved from such pathological work.

It was of very great value, however, in another way. Such theories as that which accounted for the swelling of the leg, or phlegmasia dolens, by supposed metastasis of lacteal secretion, very soon retired before the scalpel of the pathologist. The result of all this is, that we have some chance now of succeeding, after the separation of many pieces which would not fit together, in completing a puzzle of really no great complexity.

If it were asked why Gordon's theory did not find acceptance with pathological investigators (for we may observe that there were some of these who were distinguished for an extensive knowledge of the disease in all its forms, and had studied carefully all its symptoms), we must look for an answer in the supposition, that the pathological mind is of such a character as never to feel satisfied of the existence of anything without direct evidence, and then only when the method of demonstration employed is one with which it is familiar. The pathological mind is not a credulous one. It has a good deal of confidence in its own powers, and it likes to use its own visual organs. It would meet such a theory as Gordon's with an avowal of the greatest willingness to believe in the existence of a specific poison, provided only it could be shown the poison. To imagine that it could be contented with less is to do

injustice to its common sense and acuteness. For such a mind to conceive of an atom is almost impossible; it appears to it practically useless to do so, and to range beyond the sharply defined cordon of the demonstrable is scientifically reprehensible.

Let us examine to what pathology led. The principal effect was a very excellent classification of morbid changes, which has been followed closely by continental authors, and is still preserved by systematic writers in all countries. When it was found that descriptions of particular forms of inflammation were true for the particular cases in which they occurred, but not for all forms of the fever, we can understand that general views would soon embrace the apparently unconnected series of various morbid appearances which have been recorded. It soon appeared quite possible for various structures in the abdomen to be severally or simultaneously affected, or even that there might be well marked, though very different, pathological alterations, and yet that the cases were correctly described as forms of puerperal fever. Thus a simple classification was adopted under the general term uterine or puerperal inflammation, which included: 1. Inflammation of the peritoneal covering of the uterus and the peritoneal sac; 2. Inflammation of the uterine appendages; viz., the ovaria, Fallopian tubes, and broad ligaments; 3. Inflammation and softening of the proper or muscular tissue of the uterus; 4. Inflammation and suppuration of the absorbents and veins of the uterus. Each separate structure was thus carefully examined, and its alterations recorded.

There is a great deal to admire in the very exact and truthful descriptions, which make the works of the pathologists, to whom we are indebted for these valuable aids to our knowledge of puerperal fever, so well deserving of our regard. Probably the very fact, that a rigid exclusion of etiological influences in connection with these pathological conditions was observed by the school of pathologists to which I have referred, may be the cause of their work being so valuable. That publication of Dr. Baillie's, which contained nothing but careful and elaborate engravings, with the simplest descriptions possible, was the type of scholarly composition and masterly anatomical and pathological skill. There can be no doubt that, since the productions of that period from which we have traced the commencement of our history, nothing has ever appeared to compare with those of our own country. There were no uncertainty as to facts, no hasty generalisation, and no attempts at artificial classification, amongst those that followed close upon Baillie's model. So carefully did they attach themselves to the firm rock of certain truth, and so sure were they of the ground on which they stood, that they would have wondered at many since their day who have been looking so long into the hazy atmosphere that surrounds those difficult regions of the origin of life and disease, as to have forgotten to move on whilst dreamingly attempting to define the misty outlines of forms of things beyond their power of perception or comprehension. Such is the feeling they would have experienced, combined with one of pity, if they had heard some of us say that the very foundations of pathology are uncertain; that we know not quite where we are, or what next we may see. This brings me back to an urgent claim for the careful preservation amongst us of our peculiarly national method of observation, which, while accurate in detail and cautious in expression, still considers the best proof of its value to be the benefit it confers by its practical application.

To return to our subject, we have to notice the important extension of the theory of inflammation to the explanation of the connection between that condition which was known as phlegmasia dolens, and certain morbid changes in the structures of the venous system of the uterus; that is to say, when the symptoms which had previously been referred to metastatic lacteal secretion or pressure upon the lymphatics, were found to depend upon obstruction to the venous circulation.

The term phlebitis assumes the possibility of the veins, as separate structures, being affected by inflammation. Various changes of their lining membrane, and the existence of pus within the vessels, were considered satisfactory evidence of inflammatory action; and then followed the theory of pyæmia or puerperal purulent infection, arising from suppurative phlebitis. We will not stop to discuss just now whether these views were altogether correct. There is no doubt that, as far as the facts were concerned, they led to very important results.

It was shown that phlebitis might occur, not only in the puerperal condition, but also as a consequence of suppressed menstruation; in cases, too, of malignant ulceration of the os and cervix of the uterus; in certain forms of tuberculous disease; also as a consequence of abortion, and after operations for fibrous and other tumours of the uterus. The theory of puerperal purulent infection was supported by the popular school of medicine in France, and was ably argued by the late Professor Trousseau. It never was very generally received amongst ourselves, for the reason that we did not find it in accordance with clinical experience.

I can recommend the analysis of Trousseau's lectures on this subject to those who are interested in the comparison between French and the English character of mind, as influencing the scientific study of the phenomena of disease. Trousseau entertained the idea that puerperal fever depended on purulent infection, and that such infection was always to be traced to a wound; or that suppurative phlebitis might follow a wound, and pus might thus be introduced into the system. He assumed, or, rather, fell back upon, an old theory, which has often been employed to explain many circumstances connected with the puerperal condition. As far as it bears upon our subject, which, I may remind you, is the specifically poisonous origin of the fever, we can fairly allow it to be passed over, at least at present. The theory to which I allude is this: that a certain diathesis characterises the puerperal state.

We can easily understand how the theory of a particular diathesis was also employed to explain that condition of the veins which we term thrombosis, or, rather, that state of the blood which was supposed to be the primary cause of its coagulation; and a further application of somewhat the same theory to tuberculous and cancerous cases, which assumed in the latter instance the more familiar title of cachexia, was conveniently used to explain the occurrence of the various pathological conditions, and the symptoms arising from them which were found to be common to these diseases as well as to the puerperal state.

The last edition of Trousseau's lectures was published some years after Semmelweis's work, in which, as we shall see, it was clearly shown that cases of carcinoma of the uterus in the same ward with puerperal cases might produce that fever. This was undoubtedly, though a simple observation, one of considerable importance in bringing clinical evidence into consistent accordance with pathological facts. There is one remark of Trousseau's, however, which clearly shows that he was quite aware of the weakness of his argument in favour of diathetic influence. "The same conditions," he says, "exist in nearly every recently delivered woman, or in all cachectic persons," yet "phlegmasia dolens is not a necessary complication in either class of patients"; from which he concludes very candidly that "consequently there exists a special cause which is unknown". It happened about this time that the doctrines of the German pathologists were exciting a good deal of attention in their bearing on the theory of inflammation. Those important changes which are observed in the various forms of puerperal inflammation were subjected to the theory which Virchow expounded, of the origin of inflammation in certain alterations in connective tissue. It is not essential to our argument to consider whether that theory be correct or not; for it is, as far as we can judge at present, not of very great practical importance whether the process of inflammation commence with active changes in the cellular elements of connective tissue, or in the exudation of the corpuscular elements of circulating fluids. They both agree in allowing the existence of some primary cause for the tissue-changes; they only differ in respect to the earliest effects which that cause produces. It is now generally admitted that the connective tissue is that which is chiefly affected in puerperal inflammation in all its various forms; that is to say, in metritis, phlebitis, and others; and the term cellulitis is more commonly used than any other, at least by those who receive the recent doctrines on inflammation.

Clinical experience and pathological examination of this question lead me to concur entirely in these views. Instead of regarding a vein as a separate structure, and thus admitting the term phlebitis to be pathologically correct, it appears that we must refer the coagulation of the blood, which is the consequence of so-called phlebitis, to changes in the connective tissue which surrounds the vessels. On this point, therefore, we are obliged to differ from the pathologists whom Trousseau followed, as well as from those who consider that the tissue-changes are induced by coagulation of the blood or thrombosis, whatever that may depend upon.

There is not much difficulty in comprehending the process by which a vein becomes filled with coagulum in phlegmasia dolens, whether it occur in the puerperal state, or under any other circumstances. Perhaps the best instance from which we can inform ourselves of the relation which the process of coagulation bears to that of cellulitis, is one of those rapidly fatal cases of the disease in which the large vessels which unite to form the vena cava ascendens are filled with coagula. By removing the main trunks contained in the pelvis, together with the adjacent arteries, as high as the diaphragm, we can determine by dissection the exact points where the coagula terminate. If we then examine the condition of the cellular tissue surrounding the vessel under inspection, it will be found that the external changes are in advance of the coagulum, assuming that both processes are taking place in the direction of the venous circulation. As a matter of demonstration, we may insert a needle through the vein at the point where the inflammatory changes are seen to terminate; and, on comparing its position with that of the termination of the coagulum, we may measure the distance be-

tween them. This may amount to an inch or more; but, to a great extent, it appears to depend on the number of the lateral veins that enter the vessel between those two points. The orifices of the lateral veins are generally distinguished by a small projecting coagulum, which is much less firm than that of the principal coagulum. The space between the two points is not empty, but the blood which it contains is in the same condition as that which fills the vena cava itself, and generally distends the right cardiac chambers. It is satisfactory to find that this view of the pathology of phlebitis, using the word under correction, is admitted by the leading pathologists in Germany, and that they are inclined to adopt it in preference to the theory of thrombosis or primary coagulation.

We may dismiss this part of our subject with one or two brief remarks. It may be asked, How are we to explain the formation of pus in veins on the supposition that the connective tissue externally to them is primarily affected? We should reply to this: that there is evidence to prove that the different tissues of which the venous canals are composed participate very soon in the changes of the connective tissue; that the termination of the inflammatory process in any locality is the formation of pus, and that an abscess may form in such a position and in such a manner as to allow of a communication between the collection of pus and the venous canal. If, again, the question be put to us, Can the lining membrane of a vein secrete pus in the same way that the pleural membranes, the pericardium, or peritoneum are known to do? we can only answer that the epithelial surface of a vein may exhibit the ordinary changes which succeed one another in the stages of inflammation, and that in the final stage pus-corpuscles may be secreted, or rather developed, but only when the epithelial surface has been destroyed. The practical value of these pathological researches has been to afford us very valuable assistance, not in the elucidation of the etiology of puerperal fever, but in the explanation of several symptoms which were previously unaccountable, such as those resulting from embolism, coagulation of blood in the right side of the heart, the formation of secondary abscesses in various organs and tissues, and the constitutional disturbance which is produced by them.

I shall now request your attention to those contributions which were made in Germany to the etiology of puerperal fever by Semmelweis. Quite independently of his relative personal merits as a scientific observer, we may simply confine ourselves at first to the evidence which he offers on the subject of the contagious nature of the fever. After perusing the first few pages of his work, we find that he presents himself to us as an independent witness. There is also the manner which favourably impresses us with the idea, that he would not assert anything which he could not prove; on the contrary, we feel that he rather tires us with details. He does not mix up conjecture or theory with fact, though he may indulge too much in arguments which are intended to prove certain conclusions almost self-evident. The method of investigation pursued by Semmelweis was much the same as that followed by Gordon, and the proposition he supported was, like his, that puerperal fever is a disease (essentially) produced by the introduction of a septic poison into the system. Gordon, as we have seen, declined to express any opinion on what the poison might be; but Semmelweis did not hesitate to state that it was generated in the foul organised substance which results from the decomposition of animal matter. The work does not contain any original contributions to the pathology of the disease, and in that respect, as an observer of pathological conditions, he appears to me to have been decidedly inferior to Gordon.

Semmelweis argues his point somewhat in the following manner.

"We see that the great lying in institutions are singularly subject to occasional outbreaks of this disease, and the danger to puerperal women is very much greater in those institutions than in separate domiciles. In those hospitals where students are instructed, and are in the habit of coming to the wards, and to the examination of cases from the dissecting-room, the disease is more frequent and the mortality greater than when only midwives are admitted for instruction. To prove this, we have such and such a tabulated register of cases, which shows a mortality under one system of 10 per cent., as compared with $3\frac{1}{2}$ in the other. In Vienna, before 1841, the mortality in the lying-in hospital was small, when compared with that of a few years later, when the hospital had been converted from its first intention to serve for the clinical instruction of students."

"To prove that the poison was generated in the process of decomposition, and might be conveyed by the hands of attendants, a case of cancer of the uterus in a pregnant woman was the cause of a dozen fatal cases in the same ward, and the probable means of conveyance of the poison were the sponges and other things employed by the nurses, or in the course of examination by the medical attendants. We had a case, too, of necrosis of a knee-joint, which was also the cause of some fatal cases. These were clearly established facts, and they point to the

same conclusion." This is the nature of the argument, which is fairly well worked out. To show that the dissecting-room might be the source of danger, he makes the declaration:—"I myself was appointed for the second time to the clinical assistantship of the first *clinique*, and was in the habit of going into the wards after making explorations in the dead-room. The mortality in April and May was 18 per cent. and 12 per cent. respectively. During the four preceding months, I was only occasional assistant, and was not engaged in *post mortem* inquiries, nor was I obliged to examine the patients *seriatim* before the visits of the Professor. Look at the difference between the mortality in the two cases."

Then he goes on to show us from his tables that there is no connection between seasons of the year and the occurrence of the fever; so that it could not be said in any way to depend on epidemic conditions of atmosphere or temperature. There is a great deal more in the way of collateral evidence adduced by Semmelweis, but the main line of argument he pursued is thus broadly indicated. It was essentially based on statistics fairly arranged, without taking advantage of such data, and without overstraining them.

He did not neglect an important test of his views by ascertaining the effect on living animals of the artificial introduction of healthy pus into the circulation, thus proving that the symptoms could not be referred to such a cause as simple purulent infection.

I have said that Semmelweis's work consists chiefly of a collection of observations made by himself, without direct reference to the opinions of others. He does not omit, however, to mention the views of some few whom he was led to regard as the representatives of scientific thought, both in his own country and abroad. In this part of his work, however, it must be acknowledged that he gives proofs of possessing very limited knowledge indeed of the literature of his subject, and we cannot feel surprised that he finds but little difficulty in disposing of his opponents to his own satisfaction.

He brings his arguments together into a condensed conclusion at the end of his treatise in brief and forcible language. "I have shown", he says, "above that the excess of mortality in the first lying-in *clinique* in comparison with that in the second was occasioned by putrid matter, which was introduced by the hand of the examiner. I have shown that, in October 1847, the foul material of a foul cancer of the uterus produced puerperal fever. I have shown that, in November 1847, a decomposing material from a carious knee-joint produced puerperal fever; how the fever was connected with the visits of the surgeons in one hospital in particular, and how the mortality during six years was reduced to less than one per cent. when all connection with the surgical wards was broken off. It was the finger of the surgeon that carried the poison in the latter case; it was the atmosphere in the case of the knee-joint, and the air and the foul linen together in the *clinique* at Pesth, where the infection spread in spite of the washing with chlorine-water."

It may be mentioned that he had adopted the use of chlorine-water with signally good results, and derived from this fact increased support to his views of the septic origin of the disease. We will not venture to make any further comparison between the value of Semmelweis's treatise and that of Gordon. As far as the merit of priority is concerned, though the observations and opinions of the one may have been quite independent of the other, we can certainly claim for Gordon precedence in date by a considerable period.

In their style of composition, in their arrangement of data, and their logical powers, it is more than probable that we should be inclined to claim for Gordon decided superiority over Semmelweis. At the commencement of these lectures, I briefly alluded to the condition of mind which it is necessary for us to obtain in order to weigh fairly scientific evidence. It is easy to decide on the value of such evidence when we have tested it on the anvil of time. Observations and theories which have been conclusively analysed by that process naturally lose their interest. But, when we are studying the pages of history, it is the lives and characters of those who thought, and worked, and benefited us, that we feel an interest in contemplating, as well also as the lives and characters of those who did not think and did not work, and stood in the way to oppose the progress of scientific and practical knowledge. The history of this fever, if it contained nothing but facts, with the dates of their discovery, would not be a long one. The history of the erroneous ideas and statements which were advanced on the subject of its origin and nature would far surpass it in dimensions. It has been said by one who has displayed singular scientific acumen in philological research that, "for the discovery of truth, there is nothing so useful as the study of errors". It may be useful certainly to the individual who pretends to originality; but, for our purpose, I venture to think we have done well in confining our attention to the more limited object with which we started, of tracing the progress of truth through its various stages of development.

CLINICAL LECTURE

ON

CLUB-FOOT AND ITS TREATMENT.

By GEORGE BUCHANAN, A.M., M.D.,

Professor of Clinical Surgery in the University of Glasgow, Surgeon to the Western Infirmary, etc.

THERE are few operations in surgery which the surgeon approaches with more satisfaction than those for the cure of natural deformities. Amputation of limbs, resection of joints, and excision of tumours, are necessary and important as a means of saving or prolonging life after other treatment has failed to remove or arrest disease; but these are evidences of the imperfection of our knowledge of the nature and origin of many affections, and, at all events of the inefficiency of our therapeutic applications. Let us hope that the advance of pathological and therapeutical knowledge will one day diminish the number of radical operations, which at present are necessary in the treatment of surgical diseases.

But we cannot expect that any extension of our researches will diminish the number of children born with congenital deformities. Into the popularly supposed causes of these defects, it is not our place to enter; it is sufficient that they are common enough to demand a careful consideration on our part. It is very probable that many of you who are destined to become general practitioners, may never be called on to perform operations for the cure of deformities, delegating those duties to those who are to take the position of operating surgeons; but some of you will, I have no doubt, have as your sphere some place where you must rely on your own resources for every medical service demanded by your patients; and all of you will have it in your power to advise and direct patients as to the proper course to be followed. This is a most important position, for it is in early years that most of these defects can be most readily remedied. Never was this more impressed on my mind than by the case now before you. Here is a young gentleman, eighteen years of age, who has been the victim of talipes varus since infancy. The deformity seemed so hopeless to the medical attendant, that he did not venture to suggest any treatment; and the various surgeons, who were from time to time consulted, dissuaded the parents from any operative interference. Six months ago, he came to me, and, though the deformity was extreme and all the structures implicated were rendered rigid by the length of time they had been in their unnatural position, I did not despair of being able to improve his state, at least in a material degree. The result has exceeded our most sanguine expectations, and the patient is here to walk across the theatre on the sole of his foot, a thing he never did in his life till a month ago.

The further illustration of this subject will be found in connection with the case I shall now introduce, and also another in the wards, which will be operated on a short time hence. Here is a boy, aged seven years, with a well-marked example of talipes varus, or inverted club-foot. Observe the particulars of the distortion. First, the heel is raised and twisted towards the opposite foot. Second, the inside of the foot is twisted round so that the sole of the foot looks upwards, and the boy walks on the dorsum of the tarsus turned down. The sole of the foot is also curled inwards, so that the ball of the great toe is much closer to the heel than it ought to be. The whole foot is so distorted, that the only kind of boot which the boy can wear for the protection of the skin is a sort of leather bag with a strong thick sole. Let us now consider the structures concerned in this deformity. Let me remind you, then, club-foot exists in four varieties—talipes equinus, talipes calcaneus, talipes valgus, and talipes varus. Each of these varieties may depend on atony of one set of muscles, or an undue contraction of the antagonistic set. Hence we have tonic and atonic talipes. Now it is important to recognise this difference, because, though in both you may, by mechanical or operative means, restore the normal shape of the foot, yet it is in the tonic variety alone that you can promise a really favourable result as regards the future power of walking. I am far from taking a hopeless view of cases depending on muscular atony, or paralysis as it is often called, for I have had under my care a great many children in whom by persevering mechanical, gymnastic, and operative treatment I had had every reason to be satisfied with the result. The whole subject of the proper treatment of muscular atony, whether the result of deformity or prolonged retention in one position, is well deserving of notice, and I shall call your attention to it in another lecture.

The case before us is one of the tonic variety, in which the distortion is produced, or at least kept up, by the contraction or rigidity of the muscles, tendons, ligaments, and fasciæ. With regard to the

muscles, the first thing I wish to impress on you is the difference between *contraction* and *rigidity*, although these two terms are too often used indifferently. By contraction is meant the physiological action of a muscle, the vital movement produced in and by its particles. This, of course, cannot be continuous, but must be interrupted, varying with the stimulus applied to its molecules. But, by rigidity, we mean a permanent condition produced by the long retention of the muscle in one position. It loses its contractility to a great extent, and to a certain degree its elasticity, and assumes more of the nature of a tendon than a fleshy mass. Of course, there are various degrees of rigidity, but in extreme cases the above is a true description.

Examples of distortion maintained by muscular contractility are to be found in fractures and dislocations, where the abnormal position of the articulation or fragment of bone depends on the action of the muscles, to overcome which we have recourse to mechanical position, or the administration of chloroform, or both.

But in a club-foot the deformity is maintained more by mechanical rigidity than vital contractility. The muscles are shortened and stiffened in a very unyielding manner, and chloroform enables us to act on them only in so far as it abolishes pain and prevents the struggles of the patient.

There is no doubt that in persons with club-foot, who have been allowed to grow up and use the foot in walking, the bones of the tarsus become more or less altered in shape by mutual pressure, and the ligaments become shortened and stiffened; but primarily, and even in adult cases principally, the muscles are the offending structures.

In talipes varus the muscles concerned in the deformity are of two classes: those of the leg and those of the foot. The muscles of the leg which pass round the inner malleolus are more or less implicated, but it is only the *tibialis posticus* which is worthy of notice, and I believe that it is not nearly so important as many writers would seem to indicate. A muscle of its length, even when very rigid, can be stretched to a considerable degree, and if there are any cases of club-foot which can be "cured without cutting tendons", as some surgeons would have us believe, they must be very trifling examples of the deformity, and the defect must depend wholly on the long muscles of the leg, which is very rarely the case.

Turning now to the structures in the sole of the foot, we find several of these the principal, in many cases the only, cause of the distortion. The plantar fascia is always rigid and unyielding, and is stretched like a suspension-bridge across from the heel to the ball of the great toe. But I believe that there is something even more important than the fascia. My attention was first called to this matter by the unsatisfactory results of my earlier operations, in which my incisions were planned after the most reliable information I could find. I used to divide the *tendo Achillis*, the *tibialis posticus*, and the plantar fascia, all by subcutaneous incision; but, in many cases, I found either that the incurvation of the foot did not yield, or it recurred with a rapidity which showed that something more was wanted.

Reflect for a few minutes on the anatomy of the foot. Composed of a number of separated bones, articulated in such a way as to give that lightness and elasticity of step which is one of the prerogatives of man, there is one special joint on which centres its principal movement. I mean the ball and socket articulation, between the head of the astragalus and the cup of the scaphoid. The muscles of the sole are composed of two sets; one the superficial, which acts from the *os calcis* on the distal part of the foot; the other, all the deeper layers, which arising in front of the *os calcis* and astragalus, control the more minute movements, which are of such service to those who walk barefoot. The articulations in front of the astragalo-scapoid and the muscles which act on them are little, if at all concerned in club-foot, the inversion and incurvation being situated in the joint referred to, and produced by the muscles which act on it.

The *tibialis posticus* is inserted into the tuberosity of the scaphoid bone, part of the tendon being sent forward to the bones anterior to it; but the important point for the surgeon is its attachment to the scaphoid bone. When it is in a state of undue contraction or rigidity, pulls the scaphoid round upon the head of the astragalus, and so twists the foot inwards, as you may see from the dissected specimen I here show you.

But in this other dried specimen of the bones of a case of varus, you will see that there is something more. The ball of the great toe is approximated to the *os calcis* to a degree that could not be accounted for by the action of a muscle attached to the scaphoid bone.

Now, I bring back the boy who was here a short time ago, and point out to you on the inner side of the foot a thick, strong, rigid band, binding the great toe towards the heel; and, on stretching the toe, it becomes as tense as a tight-rope. The superficial part of this band, no doubt, consists of fascia, but the thick mass is the rigid and unyielding

substance of the abductor pollicis muscle. You will remember, that the relation of the plantar fascia to the muscles of the foot is peculiar. They adhere to its deep surface, and their origin is greatly extended by this adhesion of their fibres to it. On the outer edge of the foot, and to the middle of the sole, the fascia is adherent to the muscular layer as far forward as the ends of the metatarsal bones, so that there is comparatively little muscular movement in that region; and it will be remembered that the outer part of the foot, both owing to this disposition of its muscle, and the small number of articulations, is designed to be a lever of station, while the spring of the foot depends on the elasticity of the inner arch of the instep. The abductor pollicis is covered by a comparatively thin layer of fascia, but, just at the place where it lies against the flexor brevis digitorum, the fascia is thick and there is a firm dense septum between the two muscles which adheres to both. This septum is well known to anatomical students, as its dissection to expose the deeper structures of the foot is a piece of manipulation requiring much care and time. If a case of talipes varus be critically examined, it will be found that the rigid band retaining the great toe in its incurved state, corresponds precisely with the situation of the septum I have alluded to, and the fascia covering the adjacent sides of the abductor pollicis and the flexor brevis digitorum. I again show you, in this boy's foot, the prominent unyielding band in the very region I have just indicated.

Now, I believe it is the close adhesion between the muscles I have named and the inner part of the plantar fascia which renders it so difficult for the surgeon to restore the proper shape of the foot, even after a partial division of the plantar fascia. No sooner is the section made than the muscular action tends to approximate the cut edges of the fascia, and, notwithstanding every effort, causes their union in a few days. It was this result in my earlier operations, demanding fresh incision, that made me dissatisfied with the operation as I then carried it out, and made me adopt the plan I now follow.

Let us now consider the various steps of the operation required for such a case as we have just seen; and I may here state that I do them all at the same time, and not in successive stages, as is often done; except in cases where the first incision in the sole is not sufficient, as is not unfrequently the case in adults.

The first part of the operation is the division of the *tendo Achillis*, which may be done either by introducing the tenotomy-knife in front of it and cutting outwards to the skin, or, as I always do, passing the knife superficial to it while it is in a state of relaxation, and cutting down upon it while extended till it snaps asunder. There are very few cases of talipes varus in which this is not necessary as a preliminary. Many surgeons do this part of the operation some weeks before attempting the rest; but I have seen no reason to depart from the plan of doing all the cutting part at the same time.

The second part of the operation, where it is necessary, is the division of the *tibialis posticus*. This I believe to be very seldom required. I am convinced of this, that if those surgeons who are in the habit of cutting it above the malleolus internus as the second part of the operation would delay it till the following proceeding is adopted, they would find very few cases in which it would be necessary. I explain this by the fact that it is really not often affected so much as is supposed; and also that, being a long muscle, it may be stretched in the subsequent manipulations. I never cut it above the malleolus, but I have seen it done by others; and I can confidently state that, in at least some in which the operator had satisfied himself that the division was effected, there was no release to the foot, from its distorted state—in fact, it remained bound in its abnormal shape by the tissues next to be dealt with. If I were quite satisfied that it was very tight in an adult with talipes, I should divide, as I have mentioned, above the malleolus; but, in children, I prefer to make the incision just proximal to its insertion into the scaphoid bone, through the same opening as is necessary for the next part of the operative proceedings.

The third stage is the division of those structures which maintain the incurvation of the astragalo-scapoid joint, to which I have already referred, and which pull the ball of the great toe towards the heel. To effect this, the tenotomy-knife is to be entered at the inner edge of the foot just behind the tuberosity of the scaphoid bone. It is to be kept flat and pushed under the skin till it reaches to the middle of the sole; then it is to be turned with its edge to the plantar fascia, which is to be divided by a sawing movement of the knife, the parts being kept in extreme tension by an assistant. When the knife has passed through this part of the fascia, the point is to be dipped down so as to divide as far as possible the septum of fascia described before, and then the whole of the muscular substance down to the tuberosity of the scaphoid is to be cut through; and, before removing the knife from the aperture of entrance, the point may again be depressed, and the tendon of the *tibialis posticus* divided.

This may seem a somewhat heroic incision, but its effects on the distortion are most satisfactory; and I may state that I have never experienced any bad results from it, though I am in the habit of operating in this way many times annually. I believe that sometimes the internal plantar nerve and artery may be cut; but the artery in a child is a mere trifle, and never gives rise to hæmorrhage after the application of a bandage, and, as for the nerve, we know how rapidly repair of divided nerves occurs. At all events, experience shows that such incisions may be made subcutaneously with impunity, and with results which warrant their performance. When the muscular substance of the abductor pollicis is divided, the tendency of the plantar fascia to come together is obviated, at least, till the muscle reunites; and if means are taken to prevent that for a time, the cure of the deformity is rapid.

When the incisions are completed, a pad of lint is to be placed on each of the apertures of entrance of the knife and a bandage applied round the foot and ankle. I then usually put on the club-foot spring-boot for an hour or two. But the operative part, although very important, is by no means the only part of the treatment. For days, weeks, and months, the most patient and persevering manipulations must be carried on. I do not approve of keeping the foot in a rigid apparatus, and gradually screwing it round to the proper shape if that could be done. For at least a week or ten days, the apparatus is to be put on first for an hour or two morning and evening, adding an hour daily, till at last it is only removed for an hour morning and evening in order to undergo the necessary manipulations. These for the first week or two must be performed by the surgeon or his assistant, or by a skilled nurse, as no parent will undertake them at the outset. They are the *douche*, frictions, shampooing, and, above all, the systematic twisting of the foot towards its natural position. This is the most important part of the treatment, for during it the muscles are brought into play to a certain extent; and, if the child be old enough, or sufficiently intelligent, you will find that it will use its antagonistic muscles to assist you to turn out the foot, in order to avoid the pain produced by the twisting, which is always increased at first by the involuntary, though vain, endeavour to struggle against you. So important is this assistance, that I am in the habit of offering small rewards to the child to bribe him to turn out his foot without assistance. It not only helps you to overcome the deformity, but it adds tone to the peronei muscles, and is of singular value when you allow the child to begin to walk, which at first must always be done while the boot is worn.

Such being the chief points of importance to guide you in the management of such a case, I shall now again bring in the boy and make the incisions I described. The subsequent treatment will be done in the ward for a few days by myself, and then he will be committed to the charge of three dressers, who will on alternate days perform the manipulation described at the end of the lecture.

NOTE ON LIGATURE OF THE LINGUAL ARTERY IN CASES OF CANCROID DISEASE OF THE TONGUE.

WITH CASES IN THE PRACTICE OF M. DEMARQUAY, SURGEON TO THE MAISON DE SANTÉ, PARIS.

[Communicated by M. E. SCHWARZ, Interne of the Paris Hospitals.]

LIGATURE of the lingual arteries has been employed in many cases of cancrroid of the tongue, with three distinct objects:

1. To stop hæmorrhage in cases of cancrroid, in which it is very common;
2. To prevent hæmorrhage in operations on the tongue;
3. To ward off the spread of the tumour to other parts, and to cause it to atrophy.

In the first and second cases, in consequence of the very slight anastomoses between the arteries on the two sides of the tongue, ligature of the lingual artery has afforded excellent results; and all surgeons have been well satisfied with it in cases for which it has been indicated. But opinions differ when the third case is in question.

The honour of having been the first to perform ligature of a vessel, in order to produce atrophy of a tumour which it nourishes, is due to Harvey; and it is on the basis of the same physiological principles that Mirault d'Angers, Moore, Liston, etc., and M. Demarquay, have performed ligature of the lingual arteries to produce atrophy of cancrroids of the tongue. In 1868, M. Demarquay, Surgeon of the Maison de Santé, published a memoir in the *Archives Générales de Médecine*, in which he summarised all that had been done in the matter, at the same time giving precise directions for tying the artery with ease; and praising ligature, not as a curative, but as a palliative means. He

gives reports of twelve cases of ligature of the lingual arteries, of which eight were made with the object of producing atrophy of the artery.

In 1869, M. Broca tied the common carotid artery in order to produce atrophy of a cancrroid affecting one side of the tongue. Mauvoisin has added to these cases another in which M. Broca performed ligature of the external carotid: and, in concluding his thesis, he recommends ligature of the lingual artery as a last resource. To these cases now remain to be added three more instances of ligature of the lingual artery performed by M. Demarquay. These cases give the opportunity of examining: 1. What are the indications for this operation? 2. When must one or both of the lingual arteries be tied? 3. What are the immediate and the consecutive results of the operation?

1. *What are the indications for ligature?* A clear indication for ligature is when repeated hæmorrhages occur, which quickly exhaust the patient if they be not arrested. In a certain number of cases, infection of the lymphatic glands is a second indication. It is, indeed, clear that, if the ulceration or a cancerous growth on the tongue be limited in extent and capable of being completely removed, no infection of the submaxillary glands being present, ablation will be preferable; but if, on the contrary, the patient have, together with ulceration or circumscribed growths, a cancerous glandular lump indicating a tendency to invasion, the operation, if performed, should not only extend to the tongue, but also to the glands. This is generally difficult, and is likely to be incomplete when the cervical glands are implicated. As a matter of course, the ligature of the lingual artery will itself be rendered less easy by the presence of glands; but, upon the whole, it will be less dangerous than the preceding operation: and, besides, recourse can then be had to the ligature of the large trunks of origin, as has been done.

Great extent of the lesion is a third indication for ligature. When it is impossible to reach directly the limits of the evil with the *caneur* or galvanic cautery, ligature, by retarding its progress, will certainly prolong the life of the patient, or will arrest certain accidents.

A fourth indication is drawn from the size of the tumour, and from the symptoms of asphyxia and dysphagia which it then produces. It is specially in these cases that ligature of the lingual artery has often produced remarkable results. Additional indications may be derived from the cachectic or anæmic condition of the patient, very advanced age, or the harmlessness of the operation in itself. Such is a general view of the circumstances in which ligature of the lingual artery should by choice be performed.

2. *Should one or both arteries be tied?* In the cases quoted in M. Demarquay's memoir in the *Archives de Médecine* for 1868, he tied the two lingual arteries—a practice which has usually been followed. The sufficiently clear demonstration of the division of the circulatory system of the tongue into two parts, right and left, will afford a basis for judging of the opportuneness of single or double ligature, according to the situation of the points invaded by the epitheliomatous degeneration. If one of the edges or sides of the tongue be attacked, which often occurs, ligature of the corresponding lingual artery will suffice. If, on the contrary, the tumour or the ulceration be median, or, whilst invading one whole side, trespass also on the other, the two arteries must be tied, and that in two different operations.

The results obtained by simple or bilateral ligature are as follows. This operation affects the local condition of the lesion and the general condition of the patient through the medium of the very varied functions in which the tongue has a share. The following facts have been observed almost immediately after the ligature of one or both arteries, according to the existing conditions.

There is generally, at the end of twenty-four hours, a notable subsidence of the tumour, a diminution of the ichorous and fetid secretion of the ulcer, and a distinct softening of the tumour. These results are almost immediate. The functional results are no less remarkable, and even more marked. Speech becomes freer, mastication and deglutition easier; the patient can again keep up his strength by taking food, and his appetite is improved. If dyspnea had previously been present, respiration becomes almost normal. These more or less immediate results are remarkable. The relief afforded to the patient is most often very remarkable: the more so, as the operation is almost always completely inoffensive, and gives only a little pain when the base of the tongue is moved during deglutition.

The consecutive results are as follows. Ligature of one or both linguals is evidently only performed with the object of palliating the evil, and, considering the circumstances in which it is indicated, it is impossible to pretend that it will arrest the progress of the disease or even make it retrograde. Thus, after a longer or shorter lapse of time which has not yet been defined by the majority of writers, the affection continues and resumes its progress; the more so, that the glandular infection has not been in the least arrested, and the patient is carried

off either by an intercurrent complication, or by the gradual invasion of the tumour, or by the recurrence of symptoms which were only temporarily suspended by ligature.

Before concluding, I will state the results of three new cases of ligature of one lingual artery, with the object of arresting the progress of lingual canceroids.

The first case was that of a man aged 68, who came into M. Demarquay's wards on October 20th, 1874, suffering from a cancer of the tongue, which had attacked all the left half of the organ, but did not pass the median line. There was a deep fetid and sanious ulcer, bleeding easily; the patient swallowed with difficulty; his speech was much impeded in consequence of the almost complete immobility of the tongue. The submaxillary glands were lumpy. On November 6th, the lingual artery was tied outside the hyoglossus muscle, and the lump of submaxillary glands was removed during the operation. On November 7th, a notable depression of the lingual tumour of the left side was noted. There was less ichorous secretion; speech was more easy, and the dysphagia was diminished; the tongue was not so hard. On November 12th, the ligature came away; from the 12th to the 24th, the patient had a slight increase of disorder. There were redness and hyperæsthesia of the whole of the buccal mucous membrane. All of these symptoms disappeared by degrees. On December 27th, the patient's general condition was more satisfactory; his appetite was good; he swallowed easily, spoke in a comprehensible manner, and the secretions from the part had but little smell. The ulceration had scarcely increased at all. The pains of which the patient complained before the operation had not disappeared.

The second case was that of an old man aged 69. He came in on November 19th, 1874, suffering from a canceroid of the tongue, for which he had undergone an operation. The first time on the 22nd of last May. The right anterior fourth of the tongue was removed; but he had a recurrence of the disease at the end of about five months. On November 13th, he was attacked by violent buccal hæmorrhage, which weakened him much; it only lasted eight minutes, but the quantity of blood lost was very considerable. For about a month he had felt very severe pains in the whole of the right half of the head, of a neuralgic character, returning in paroxysms. The anterior fourth of the tongue had been removed, the cicatrix was healthy, but the floor of the mouth and the base of the organ at the same side were invaded by a deep ulceration, covered with foul detritus. Its edges were indurated. The submaxillary glands and a submental one were enlarged. Salivation was very profuse, and gave much annoyance to the patient, who spoke with difficulty, and could scarcely swallow anything but liquids. He was ordered a gargle of permanganate of potash, with sulphate of quinine internally. On November 24th, M. Demarquay proposed ligature of the right lingual artery, and succeeded in tying the vessel, notwithstanding the size of the patient's neck and the submaxillary glands. The same evening, a notable reduction of the tumour was observed on the side where the artery had been tied. Salivation was less abundant; the patient felt very well, and had only a little difficulty in swallowing, in consequence of the movements of the subhyoidæan region where the ligature (outside the hyoglossus) was applied. On November 28th and the following days, there was no accident. Speech became more easy; the ulcer became cleaner, and even seemed to diminish. On November 30th, the patient had an attack of gout. On December 3rd, the ligature came away. On December 20th, the patient was much better than when he came into the hospital, and went out. The ulcer was clean, the tongue was less indurated; speech and deglutition were easy; there was no more tendency to hæmorrhage; and the general condition was good.

The third case was that of a man aged 62, suffering from a canceroid of the tongue, which invaded both sides of the organ, implicating the base. There were enlarged submaxillary glands on both sides; deglutition and speech were impeded; and there was copious salivation. On December 3rd, ligature of the lingual artery of the right side was performed, and a great reduction of the tumour on that side was noted. The salivary secretion was diminished. There were no accidents on the following days, and less difficulty in speaking and swallowing, though considerable pain was felt during the first thirty-six hours. M. Demarquay wished to perform ligature of the lingual artery on the other side; but the patient left the ward, finding himself sufficiently relieved.

In conclusion, the results obtained in these three cases of unilateral ligature are very satisfactory. Without at all pretending to bring forward this operation as one to be often employed in cases of epithelioma of the tongue, we still think that it is likely to render essential service to patients in the conditions pointed out, and that this treatment should be extended to a greater number of cases than it has hitherto been.

A CASE OF MEDIASTINAL CANCEROUS TUMOUR, LEADING TO OCCLUSION OF THE RIGHT BRONCHUS, AND CONSEQUENT COLLAPSE OF THE RIGHT LUNG, AND CARDIAC DISPLACEMENT.

By I. BURNEY YEO, M.B., M.R.C.P.,

Senior Assistant-Physician in King's College Hospital, and Assistant-Physician to the Brompton Hospital.

S. A., AGED 53, a picture-colourer, first came under my observation as an out-patient at the Brompton Hospital on November 11th, 1874. I was at once struck by his appearance. The dusky pallor of his countenance, his emaciation, his breathlessness, which was not of a noisy sort, but what might be called a silent dyspnoea, gave warning of the presence of serious disease. He immediately seated himself in a chair, and appeared reluctant to move, as the smallest attempt at exertion increased his difficulty of breathing. It was also a trouble to him to talk, and it was with some difficulty, therefore, that I obtained from him the following history.

His father was a healthy man, and lived to be 75; but his mother and a sister had died of phthisis, and he had also lost another sister from cancer of the uterus. With the exception of attacks of winter-cough, he had always had good health until about six months ago. He had always been temperate. About twenty years ago, he contracted a chancre, which was followed by an eruption.

His present illness dated from last April. He then had what he was told was an attack of bronchitis. He recovered from this to a certain extent; but, in the beginning of June, he thought he "caught cold again". He had shiverings, and felt pain and "pressure" in the right side. Three days after the shiverings, he took to his bed, and remained there for two months, suffering from difficulty of breathing and cough, with only slight expectoration. He was then told that he was suffering from pleurisy, and that there was fluid in the right pleural cavity. In August, he was better; he was told that the fluid had been absorbed. He got up and went about.

Towards the end of October, he found himself becoming worse again. He suffered much from dyspnoea on the least exertion, and he had a troublesome hard cough. He had been losing flesh for six months. He at this time presented the appearance of a pale emaciated man; pale, as I have said, with a dusky and livid pallor; complaining of great general weakness and distressing dyspnoea on the least exertion. He had a slight cough, with a little muco-purulent expectoration. His pulse was small, compressible, and very rapid—140 to 160 in the minute. Respirations, 32. On stripping him and examining his chest, the first thing that struck me was a remarkable displacement of the heart, which was easily seen and felt beating entirely on the right side of the chest. There was diffused cardiac impulse occupying the right mammary region, and extending downwards to the right side of the ensiform cartilage. But over the whole normal cardiac area on the left side there was clear pulmonary resonance. On inspiration, it was observed that the left side of the chest expanded much more than the right. Over the whole of the right side of the chest, there was dullness on percussion, both anteriorly and posteriorly. The left side, on the other hand, was superresonant in front and behind, this resonance extending beyond the middle line in front and nearly reaching the right margin of the sternum. There was very little diffused inspiratory movement even on the left side of the chest, and it was clear that the left lung was greatly distended and emphysematous. On auscultation, there was no natural respiratory sound to be heard on the right side; a moderately loud rhonchus was occasionally audible at the right base, and a distant, faint, blowing sound with the expiration over the right scapular region. Later on, an indistinct crepitant *râle* was heard in the right suprapinnous fossa.

There was very little vocal fremitus either in front or behind on this side, but it was not entirely absent. A rhonchus was also heard at the base of the left lung.

The patient complained of no pain or tenderness anywhere. There was no noisy breathing; no stridor; the voice-sounds, though somewhat feeble, were quite natural. There were no distension of the superficial veins, no edema, no marked pressure-signs of any kind. On his first application as an out-patient, he declined to be taken into the hospital, as he had, he said, some work to do at home. He attended again on November 21st, when I was unable to be at the hospital, and, therefore, did not see him. But, on December 5th, he came, for the third time, as an out-patient; and, as he found he was losing strength rapidly, and that his symptoms had been in no degree

relieved, he was induced to accept my offer to make him an in-patient in King's College Hospital; and, on December 10th, he was admitted into that institution under my care. On his admission, and as long as he was in the hospital, the physical signs were, and remained, precisely as I have given them above.

After a few days' rest in bed, his symptoms were greatly relieved. His dyspnoea was scarcely observable; his appetite was good; he slept well, and was cheerful, and, save when occasional slight attacks of cough and expectoration brought on an access of dyspnoea, he presented few subjective symptoms of any distinct import.

After, however, he had been in the hospital about ten days, the cold weather, which had been for a long time severe, became intense; this seemed to depress him physically; he became somewhat confused and incoherent in his manner, and, on the 23rd, somewhat unexpectedly, he died from exhaustion, after only thirteen days in hospital. There was no aggravation whatever of the chest-symptoms; but he had not vital energy enough to resist the continued depressing influences of protracted cold. A case of thoracic aneurism in the very next bed to this patient died a few days afterwards in precisely the same manner, not directly from the effects of the aneurism, but from exhaustion induced, to a great extent, by the depressing influence of cold.

We did not feel quite sure what we should find on *post mortem* examination. In its general aspect, the case resembled one of malignant tumour within the thorax; but, save the dyspnoea, there were none of those pressure-signs which generally accompany such disease; and, with rest in bed, the dyspnoea disappeared. He had no pain, no orthopnoea, no anxiety. He ate and drank and slept well. There was very little cough; indeed, there was an almost entire absence of subjective symptoms. We had a history of a previous attack or attacks of pleurisy, and we were assured that there had been an effusion into the right pleura, and subsequent absorption of the fluid. There was clearly considerable contraction of the right lung, sufficient to cause the heart to be displaced from the left to the right side of the chest; there was also considerable compensatory expansion of the left lung. But there was no noticeable retraction of the left side. I have seen the heart displaced in this way, drawn over to the right side, from the contraction of a large cavity in the upper part of the right lung; but, in such a case, there is also usually very marked flattening or depression of the chest-wall opposite the seat of the cavity; or the heart may be pushed over to the right by a large effusion of fluid into the left pleura, and may contract adhesions to the right chest-wall, and so be permanently fixed there. But this was certainly not the case in the instance before us; for the left side was clearly occupied by a greatly distended and very emphysematous lung.

In the next place, the question arose, Could the symptoms and physical signs observed in this case be satisfactorily accounted for by supposing that there had been an effusion of fluid into the right pleural cavity; that this had been slowly absorbed; and that the lung, having been prevented from expanding by bands of lymph, and the chest-walls prevented by rigidity from retracting, the left lung had slowly dilated, and pushed the heart over to the right side? The dyspnoea on exertion, which was the chief subjective symptom, would thus be accounted for by the contraction and compression of the right lung, the highly emphysematous distension of the left lung, and the cardiac displacement. The absence of all pain and tenderness, of all pressure-signs, such as dilated veins, stridor, dysphagia, aphonia, etc., and the disappearance of the dyspnoea with rest in bed—all these circumstances, together with the stationary condition of the physical signs, tended to obscure the nature of the case, although they in no way diminished its clinical interest. On the other hand, the evident cachexia, the emaciation, the peculiar dingy pallor of the countenance, pointed to the probable existence of malignant disease within the chest.

Post mortem examination revealed the existence of a tumour about the size of a large orange, situated in the posterior and middle mediastinum, pushing down the base of the heart. It was of a whitish colour, and cut with a moderately firm section. It enclosed in its substance many black bronchial glands. A small process of this tumour had grown into the right bronchus, so as to almost completely occlude it. In the apex of the right lung, there were three or four rounded masses, the largest of the size of a filbert, moderately firm, and whitish in colour, and resembling in appearance the larger tumour. The right lung was firmly adherent to the chest-wall throughout, and the pleuritic adhesions were so strong, that the lung could only be removed by lacerating its substance. The lung-substance was crepitant at the apex, but the middle and lower lobes were firm and indurated from complete collapse. The left lung was markedly emphysematous. The heart was found to lie horizontally, the base turned quite to the right side, and on a level with the apex.

On microscopical examination, the tumour presented the characters

of medullary cancer; the fibrous tissue was more abundant than usual, but the cells were well marked, and contained, for the most part, several large nuclei and sometimes nucleoli.

NASOPHARYNGEAL POLYPUS: HYPERTROPHY OF THE MUCOUS MEMBRANE: TRACHEOTOMY: REMOVAL OF SUPERIOR MAXILLARY BONE: DEATH.

By ARTHUR S. UNDERHILL, M.B.

A BOY, aged 14, was brought to my surgery in the early part of last month, suffering from difficulty of swallowing and great difficulty of breathing, particularly when in the recumbent position. He had had occasional attacks of hæmorrhage from the nose. The disease commenced eight months ago with an inability to blow down the right nostril. He had gradually grown thinner: the hæmorrhage, which was sometimes very considerable, had greatly debilitated him; in fact, so weak was he that he was unable to walk any distance, or even to stand for any length of time. On examination, the soft palate on the right side was seen to be bulging considerably forwards and downwards, so as entirely to preclude the view of the pharynx; the bulging was tense, with no fluctuation. On attempting to pass the finger down the pharynx and to hook it over the soft palate, a number of small oyster-like bodies were felt entirely occluding the posterior nares and much contracting the cavity of the pharynx: they seemed to be sessile and closely packed together; no pain was felt after the manipulation, but there was very considerable hæmorrhage. In consultation with my father, I decided to perform tracheotomy as a first step, as the patient's condition was not such as to warrant a very severe operation, and it was imperative that his breathing should be relieved. The night before the operation, so great was the dyspnoea that his attendants had to constantly change his position and shake him, as they were afraid that his breathing would entirely cease.

After tracheotomy, the relief was immense. He slept well, and became very lively; but the polyp increased rapidly in size, so much so, that it became a matter of difficulty to swallow even liquids. Accordingly, as a *dernier ressort*, excised the right superior maxillary bone fifteen days after the first operation. This I accomplished with less hæmorrhage than I anticipated. The bones, being young and soft, separated readily, thus enabling the operation to be rapidly performed. We found the mucous membrane to be everywhere very considerably thickened, and a number of small polypi varying in size from a pea to a moderately sized oyster studding everywhere the mucous membrane as far down as the finger could reach. Some of these were torn away with the finger-nail; and others lower down were removed with the *decrur*. The operation was necessarily a bloody one, and the actual cautery was necessary. The boy temporarily rallied, but gradually sank seven hours after the operation.

I wish to suggest that, in future major operations about the mouth and air-passages, tracheotomy should be performed as a first step. In this case, I was compelled to do it. Tracheotomy (at all events, before adolescence) is an easy and comparatively safe operation; and chloroform can so safely and so effectually be administered through the trachea-tube without hampering the operator or his assistants, and the patient has a free opening to breathe through, not being choked, as they usually are, by the blood which necessarily trickles down the air-passages, and when coughed up sputters over the operator. Having a tube in the trachea also allows a sponge to be placed at the back of the pharynx, and so prevents any blood from entering the œsophagus or trachea. I should recommend that a tube be used without a fenestrum, so that, if it fit the trachea well, no blood can possibly enter the trachea through it.

MATERNAL IMPRESSIONS.—A *paper* of recent papers in the JOURNAL on the subject of maternal impressions, the following may be interesting. In a *Discourse delivered at Manchester*, and published in London in the year 1698, Sir Kenelm Digby refers to the dread of a drawn sword which was manifested by James the First, and attributes it to the fright received by Mary in consequence of the murder of Rizzio in her presence when she was pregnant. Sir Kenelm was knighted by James; on that occasion, he says, the King could not look upon his sword, and adds, "he had almost thrust the point into my eye had not the Duke of Buckingham guided his hand aright".

GEORGE F. ELLIOTT, M.D.

SURGICAL MEMORANDA.

TREATMENT OF ABSCESS IN THE KNEE-JOINT BY SUBCUTANEOUS PNEUMATIC ASPIRATION.

As the pneumatic aspirator is not yet in general use among medical men, the following brief note of a case, in which its use resulted in complete success, may prove interesting and instructive.

Mrs. S., aged 26, sent for me on January 26th. She informed me that, a month previously, she had fallen down during the frost, and struck her left knee against the kerbstone. Since then, she had suffered intense pain in the joint, which had gradually increased; for several nights she had had no sleep; four days back, she had a rigor; her temperature at noon was 99.2 deg.; pulse, 80; tongue a little coated. On examining her knee, I found that it was greatly swollen, exquisitely tender to the touch, and she could not bear the least movement. There was distinct fluctuation, and I had no doubt that fluid was in the cavity of the joint. As she had not slept for several nights, I ordered her twenty-five grains of chloral at bedtime; but the pain was so intense, that it gave her no sleep. I asked my partner Dr. Gibbings to see the lady with me; and, he agreeing with my view of the case, I determined to try pneumatic aspiration. The lady would not hear of this being done without chloroform; and, as she was in very great pain, and we were anxious to further examine the joint, Dr. Gibbings administered the anæsthetic, and I passed the second largest of Messrs. Weiss and Son's needles into the joint, when about two ounces of thick pus, mixed with blood and broken-down-looking tissue, passed into the exhausted reservoir. The patient quickly recovered from the chloroform, and said the joint felt much easier. I put her on a back splint, and gave a grain of opium at bedtime. She slept well, and the next morning was quite free from pain. I kept on the splint for a fortnight, and then began careful passive motion. She is now well, and has gone to the country. The knee feels weak, and is a little stiff, but this inconvenience is gradually passing away.

FREDERICK H. DALY, M.D., Dalston.

CASE OF SPINA BIFIDA TREATED BY INJECTION OF SOLUTION OF IODINE: DEATH.

On September 16th, I was asked to see a child, born the day before, and said to be "not right". On examining the child, it appeared to be a feeble, not well nourished infant. It had a large fluctuating tumour over the last dorsal and two upper lumbar vertebrae. The legs and feet were much deformed, there being *talipes varus* of both feet, whilst both legs and feet were rotated ninety degrees outwards, principally through unrestrained action of the sartorius. Both legs, and especially the right, were flexed on to the belly, by unrestrained action of the rectus. There was paralysis of the levatores ani, so that the natural fold of the buttocks was wanting, and the anus appeared as a slight protuberance on a tolerably smoothly rounded surface. There appeared to be paralysis of all the muscles of the backs of the legs and thighs, and tickling the soles of the feet gave rise to no movements. Fæces appeared to be constantly escaping from the rectum, as the surface of the tumour gave signs of irritation from friction; and, as there were no likelihoods of the child becoming stronger, I decided not to postpone the operation of injecting the solution of iodine in the manner successfully followed out by Dr. Morton. On the 18th, in company with my friend Mr. W. H. Moore of this town, I drew off three drachms of clear fluid, and, taking great care that the needle should not cross the middle line lest it should come into contact with the spinal cord, I then injected half a drachm of Morton's solution. Neither part of the operation seemed to give much pain. The child cried a little just as the fluid was being injected, but stopped as soon as the needle was removed; and, after laying on a pad of carded cotton, kept *in situ* by means of strips of soap plaster, it was put to the breast and sucked well. I ordered fifteen drops of brandy every three hours. On the 19th, I was told that the child had not been well, that it had sucked once only during the night. The tumour had partly refilled. The eyes were fixedly and convulsively drawn down, the arms were rigidly extended forwards, and the hands clenched; whilst the child started convulsively on the slightest noise or movement. I ordered two grains of bromide of potassium and four minims of tincture of hyoscyamus in water every four hours. On the 20th, the child had not sucked since I saw it last, and was in severe convulsions. I had it turned on to its belly to look at the tumour, which was in about the same state as on the preceding day, and when it was turned back it had ceased to breathe.

It will be observed, that this was an unfavourable case for operation, as paralysis was so general; however, no better result could be looked

for by letting it alone, and as the operation had been so successful, it appeared to be the only means of doing it any good. No *post mortem* examination was made. I have thought it my duty to report the case, as the subject of the treatment of this complaint by injection of iodine is now under discussion, and the method has up to this time met with uninterrupted success.

J. E. BURTON, L.R.C.P. Lond., Assistant Honorary Medical Officer to the Liverpool Ladies' Charity, and Lying-in Hospital.

OBSTETRIC MEMORANDA.

VAGINISMUS.

SPASM and pain of the sphincter muscle of the vagina, on the application of a stimulus, was first described by Dr. Burns of Glasgow. He regarded it as due to a hyperæsthesia of the pudic nerve, and he often divided this nerve for its relief. In this treatment the late Sir James Simpson concurred, for he believed that "the best treatment for such cases is division of the affected nerve". But in the manner of dividing it, the two operators differed. This treatment was, at best, only palliative; for even after section of the offending nerve, the pain returned in some other part of its course, and the spasm continued. Courty treated this affection by forcible stretching with the finger and thumb, under chloroform. In this he was followed by Dr. Tilt. Scanzoni opposes the use of the knife, and "has always succeeded in bringing relief by first subduing all inflammatory complications, and next by effecting gradual dilatation by means of graduated glass specula, worn for short intervals at a time". Dr. Barnes has cured many cases by methods similar to those of Scanzoni, but he has "met with cases where the knife or scissors gave not only the quickest and most efficient relief, but also at the least cost of pain and other distress".

In the year 1857, Dr. Marion Sims had under observation, for the first time in his practice, a typical example of the disease, which he fully and graphically described. In two or three years after this, other cases of vaginismus came under his observation and treatment, and he devised an operation which happily is a certain and abiding cure for the malady. The following particulars of a case of vaginismus, which recently came under my notice, is, I think, a good example of the value of Dr. Marion Sims' mode of cure. Mrs. B., aged 25, residing a few miles from Gloucester, a fine, strong, healthy, young woman, consulted her medical man for some uterine discomfort. After digital examination, he told her that pregnancy existed, and intimated that her labour would be one of considerable difficulty, and would require both chloroform and instruments. Discrediting altogether his opinion that she was pregnant, she at once determined to come to Derby, her native place. She fell under my care. On July 14th, 1872, I examined, and found her almost at the full time of pregnancy. I found also that there existed vaginismus to a most severe degree. My examination gave her great torture, and it was with much difficulty that the index-finger of the right hand could be introduced into the vagina. On assuring my patient that she was with child, and would be delivered in not many days from that time, she was still sceptical, and pertinently asked how such a thing could be possible, since marital intercourse had never been consummated. This, I knew after my examination, and the difficulty I encountered, could not be otherwise; nevertheless, in five days thereafter, I delivered her with forceps of a full grown healthy child. It was after a rapid and excellent recovery from her confinement that I suggested to my patient the importance of having her ailment cured; and I described to her the nature of the operation and the subsequent treatment. She at once consented to undergo the operation; and accordingly, on November 5th, in conjunction with three medical friends, having placed my patient in the position for lithotomy, and fully under the influence of chloroform, I introduced a Sims' speculum into the vagina, and removed with a scalpel a strip of the width of from three quarters of an inch to an inch. The speculum, during the advance of the knife, was made to revolve round the vagina. Thus, at the moment of laying bare the fourchette, the speculum had advanced as far as the arch of the os pubis, and, when the knife had followed it to that position, the speculum had arrived again at the fourchette, from which part it was throwing a flood of light upon the knife. Thus an entire ring of mucous membrane was removed from the vagina, an operation which was greatly facilitated by the above-mentioned management of the speculum. The next point of the operation was section of the sphincter vaginae. The scalpel was introduced fully two inches into the cavity of the vagina, at a point about one inch on the right of the mesial line, as one sits facing the pelvis. It was carried along, making in its course a deep incision, and brought out at the fourchette. A corresponding incision was then made on the opposite side of the mesial

line, and brought out at the same point as the first; a junction having been effected between the two incisions about an inch above their termination. The two incisions, thus united, had the T-shaped character recommended by Dr. Marion Sims. The after-treatment consisted of the insertion and retention, during several hours a day, of a metallic speculum. This was inserted not long after the operation, and had a desirable effect in controlling the hæmorrhage. This patient made an excellent recovery from the operation. Twelve months ago, I delivered her of her second child at full term, and she is now two months gone with her third. I have reason to believe that conjugal relations exist without any inconvenience. F. W. WRIGHT, Derby.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

WEST RIDING ASYLUM.

OBSTRUCTION OF THE BOWEL BY A BILIARY CALCULUS.

(Under the care of Dr. CRICHTON BROWNE.)

MARIA J., aged 67, widow, a housewife from Leeds, was admitted for the second time on August 19th, 1870. She was then labouring under an attack of mild maniacal excitement, and after that period continued to suffer from similar paroxysms at very irregular intervals. Her bodily health, however, remained unimpaired, and she was indeed unusually robust and vigorous for her years, until November 1874, when, at the close of one of her ebullitions of excitement, she was prostrated by dysentery. This illness, which was sharp in character, yielded readily to treatment, but left her rather weak. She regained strength, however, and was quite herself again, when, on December 9th, she complained of sickness, with pain in the right side, in the region of the liver. Her pulse and temperature were normal, but her tongue was very dirty; and, as it was ascertained that her bowels had not acted for two days, and not even after the administration of castor-oil, a mixture of rhubarb with soda and ammonia was prescribed. On the following day, the pain in the side had entirely disappeared, but the sickness continued to be very distressing, and vomiting followed each meal. The countenance had an anxious expression, and a little shivering was from time to time experienced. The patient was placed in bed, and a gruel enema was ordered, with a diet of milk and lime-water. The enema failed to secure any evacuation of the bowels, and towards evening the vomited matter was noticed to be mixed with bile, and to have a peculiarly offensive odour. On December 11th, her features were pinched and haggard, her pulse was quick and weak, and the ejection from the stomach had become distinctly stercoraceous in character. On physical examination, it was found that there was no abdominal distension, and that pain on pressure, although present, was by no means severe. The pain was felt over a wide area, but was most distinct in the region of the descending colon, where there was some dulness on percussion, but where no tumour could be discovered. A rectal examination failed to reveal any abnormality, so enemata were again tried without relief. At 10 p.m., the vomiting continued at short intervals, and the patient was very weak and distressed. Large injections, administered by a tube passed as far as the sigmoid flexure by kneading, were given in various postures, but no beneficial result followed them. A hypodermic injection of morphia was, therefore, resorted to. On December 13th, no great change was observed in the patient's state. The abdominal tenderness had not increased, and the vomiting was rather less urgent. The pulse was weak and the tongue dry, and coated with a yellow fur. There was no discharge of any kind from the rectum. It was agreed that the patient should be kept under the influence of morphia, and that ice champagne and small quantities of concentrated nutriment should be from time to time administered, while warm fomentations were applied to the abdomen. On December 13th, the patient was weaker, but more composed; and on the 14th, at 2 A.M., she died rather suddenly from exhaustion after another attack of retching.

The *post mortem* examination was performed sixty-seven hours after death. It was found that the body was exceedingly well nourished, and was free from bruises or injuries. The brain presented a few traces of chronic degeneration, while the heart was somewhat hypertrophied, and the lungs were congested and oedematous, as well as emphysematous, at their anterior margins. In the abdomen, the liver was seen to be healthy; but around the gall-bladder, the walls of which were enormously thickened, there were discovered some greenish purulent fluid and some discoloration of the hepatic substance. On further

exploration, it was ascertained that the fundus of the gall-bladder was adherent to the duodenum, and that a ragged opening formed a communication between the biliary receptacle and the first division of the bowel. There was no evidence of peritonitis; and the cause of the intestinal obstruction was found in the jejunum, at a distance of six feet from its commencement, where a large biliary calculus was lodged. The stone, which weighed $231\frac{1}{2}$ grains, and measured an inch and a half in diameter, both longitudinally and transversely, was somewhat barrel-shaped, and presented on its upper end a smooth facet, where it had been in contact with another calculus of smaller size, which remained in the neck of the gall-bladder. It was of a dark olive brown colour, and of considerable hardness. It was not fixedly impacted in the bowel, and by forcible pressure with the finger and thumb it could be pushed onwards for a little way; but it entirely occluded the canal, so that not even water could pass it. Behind the calculus, for a distance of two feet, the mucous membrane of the jejunum was greatly thickened and swollen, and of a dark red colour, from vascular engorgement.

ABERDEEN ROYAL INFIRMARY.

CASE OF SUBPLEURAL INFLAMMATION AND ABSCESS (THORACIC CELLULITIS), COMBINED WITH PERICARDITIS.

By J. W. F. SMITH SHAND, M.D., Physician to the Infirmary.

W. R., AGED 62, a twine-spinner, was admitted into St. Nicholas Ward on May 12th, 1868, complaining of cough and weakness, with fever. He stated, that he had always enjoyed good health till two days previously, when his present illness began. One of his daughters said that a medical man had pronounced him to be labouring under diabetes, but that it had never affected his general health.

Present Condition.—The patient was seen in the ward immediately after admission, and after undergoing the fatigue of ascending the stairs. He seemed to be in a state of great exhaustion; there were lividity of the face and hands, and a cold clammy sweat over all his body.

On May 13th, he was found in bed in a semi-elevated position on account of the difficulty of his breathing. His body was bathed in perspiration. His pulse was very feeble, and above 100. In his weak state, a minute examination was not considered justifiable, but a hasty examination detected the following signs. The percussion-note was clear over both fronts of the chest, except at the upper and inner border of the right mammary region, where there was slight dulness. The percussion-note was dull over the two lower thirds of the right back. Bronchial breathing was heard over both sides of the chest, in front and behind, with occasional snoring and sibilant rhonchi. The heart-sounds were feeble; but nothing otherwise abnormal was noticed. The urine was scanty, high-coloured, of specific gravity 1028, containing neither albumen nor sugar. The bowels were regular. The sputum was scanty, slightly mucopurulent; it had never been bloody, or of an unusual colour. He was ordered a mixture containing aromatic spirit of ammonia, spirit of nitrous ether, and compound tincture of cardamoms, with peppermint water; also to have beef juice, and wine and brandy.

May 17th. The patient's condition had not varied much since admission, except that, for the last two nights, there had been delirium. The tongue was dry, with slight brown fur. The face was still livid, with a haggard expression. He has had the mixture repeated several times, as he said that it relieved the breathing. May 20th. The pulse was very feeble, but he said that he felt better. The tongue was moist and cleaning. He slept better at night, and the delirium was gone. May 25th. He was very weak. May 26th. He died early this morning.

Necropsy.—(Reported by Dr. BEVERIDGE). The body was emaciated. On opening the chest, a small collection of thick pus appeared along the lower part of the right margin of the sternum, in the loose tissue of the anterior mediastinum. The left pleura was minutely injected in patches; a few flakes and bands of soft recent lymph connected the two layers—the cavity contained a quantity of serum mixed with lymph. Both lungs were somewhat gorged and oedematous. The right pleura was finely injected throughout the greater part of its extent, but with no lymph on the surface, and no serum in its cavity. Under the pleura, in the subserous cellular layer, were numerous masses of soft recently effused lymph, forming flocculent masses, beginning partially to break down into pus, and placed chiefly on the diaphragm and ribs; the largest being situated behind, stretching from the third to the ninth rib. The pericardium was much thickened; it was much and finely injected, especially the visceral layer, which was of a deep crimson colour; the whole was covered by a very thick layer of soft lymph, much reticulated. The cavity contained ten ounces of a

yellowish fluid—serum mixed with lymph and pus. The heart was enlarged. The mitral orifice was contracted. The aorta was large, rough in the anterior, with spicula of calcareous deposit. The abdominal viscera were healthy.

REVIEWS AND NOTICES.

DE L'ALCOOLISME; DES DIVERSES FORMES DU DÉLIRE ALCOOLIQUE ET DE LEUR TRAITEMENT. Par V. MAGNAN, M.D., Médecin de Sainte-Anne. [Ouvrage couronné par l'Académie de Médecine: Prix Civrieux, concours de 1872.] Pp. 282. Paris, 1874.

ON ALCOHOLISM; ON THE DIFFERENT FORMS OF ALCOHOLIC DELIRIUM. By V. MAGNAN, M.D., Physician to the Sainte-Anne Asylum. [The work to which the Academy of Medicine adjudged the Civrieux Prize of 1872.]

IN medical and surgical practice, in the ordinary illnesses of ordinary times, in epidemic diseases, in hospitals suddenly crowded with the mutilations of battle-fields, in every diversity of sphere wherein the science and art of healing are exercised the maximum of success attends the practitioner who skilfully combines with, and often subordinates to, the treatment of the malady or mutilation, the treatment of the patient. Pneumonia, typhoid fever, or a compound fracture, demands essentially different management in persons of ordinarily sound constitution, and in persons whose economy is dominated by some morbid condition, such as tuberculosis, syphilis, or alcoholism. From a wide-extending clinical range, therefore, the able and very original work of Dr. MAGNAN claims attention. It will well repay careful study; for it bears upon it the stamp of the disciplined clinical observer and of the judicious experimental physiologist.

In the first chapter, Dr. Magnan determines the comparative action of alcohol and wormwood, and assigns to each its part in producing alcoholism. He shows that alcohol produces drunkenness; a state which begins with excitement, and may proceed through the stages of stupidity, paralysis, and anesthesia, till it culminates in coma.

On the other hand, he shows that wormwood produces phenomena of a different kind, viz., muscular twitching, giddiness, epileptic seizures, hallucinations, and delirium. These distinctive characters of alcohol and wormwood having been established, we are presented with an account of physiological and pathological researches, which may be described as an experimental elucidation of the continuous and progressive action of alcohol upon the animal economy, both in respect of the physical and intellectual disturbances which it causes, and the anatomical lesions which it produces. Dr. Magnan's experimental study of alcoholism throws an important practical light upon clinical phenomena. It enables us better to appreciate the real significance of such symptoms as tremblings and convulsive attacks, by pointing out their natural progress; and likewise furnishes us with useful indications of treatment.

The liqueur sold at the cafés and tippling-shops of Paris, and generally in continental towns, under the name of *absinthe*, is a complex compound, but the two active agents which it contains are alcohol and wormwood (*absinthe*). To the latter poison it owes its characteristic deleterious consequences. The following case, especially when studied in connection with other cases in Dr. Magnan's volume, and in connection with the histories therein given of various experiments on the lower animals, is clinically most interesting and instructive. The case was originally published by M. Motet in 1850, in his *Considérations Générales sur l'Alcoolisme, et plus particulièrement des Effets Toxiques produits sur l'Homme par la liqueur d'Absinthe*.

"M. S. (Jean Baptiste), a man, aged 31, of ordinary height and usually of good health, had been employed for three months in sculpturing the external ornaments of the Louvre Palace. He was tidy, sober, and industrious, till a fortnight before the date at which he yielded to the solicitations of his comrades to desert his work for the tippling-house. He soon got to drink ten or twelve tumblers of *absinthe* in a day, supplementing it with brandy and white wine. Some days prior to the outbreak of his delirium, he was still drinking, but without being able to get drunk; he was in a feebly-stupid state. In the night of 29th-30th May, he suddenly jumped out of bed, fancying that he saw police-constables coming to arrest him. After protesting his innocence, he sat down, and did not speak another word till it was daylight. In the morning, he became calmer, went out, drank *absinthe*, and came home in the evening in a state of complete stupefaction. With assistance he went to bed; but, scarcely had he lain down, than he was beset with frightful visions. He could not close his eyes for one instant; he got up and walked about the room, and he regarded

the persons taking care of him as his enemies. In consequence of his state occasioning alarm, he was placed in an asylum on the 31st May, 1857.

"From a knowledge of the patient's antecedents, I at first thought that he was suffering from delirium tremens. On examining the patient, I was surprised to find that he had neither restlessness nor trembling of the hands and lips. I found him seated, motionless, haggard, and anxious in face. He had more the appearance of a person under the influence of melancholia than of alcoholism. There was a something markedly peculiar in his expression, which retained all its vivacity: he moved his head with remarkable quickness from side to side, to observe all that was going on. He had not the concentration of melancholy combined with a stupid expression, nor the fixed unchanging look characteristic of melancholy. The pulse was 90, and full. The tongue was foul. The pupils were not much dilated. He answered questions, but with great indecision. He did not know exactly, he said, whether he was himself or not; 'his name was Sul, and he did not understand why people called him Monsieur Jean. He was not M. Jean—he had not killed any one': he asked, 'why he was insulted?' He heard sounds, and was always turning his head in the direction of the strange sounds. He walked with tolerable confidence, though his legs were rather feeble.

"He passed a sleepless night; he did not cry out; he spoke in a low voice; he saw flames encompassing his bed, and grimacing faces emerging from the walls. He fancied that he was being pursued by police-constables. He had no visions of horrible beasts.

"On the 1st June, all he had was a bottle of Seidlitz water, two basins of soup, and two *litres* of vegetable lemonade. He had copious evacuations. During the day and night, his condition remained the same. Next morning, he was put into a bath, where he remained for five hours, during which time, at intervals of half an hour, cold water was poured over his head. I saw the patient in his bath; he then seemed less agitated. This change for the better was only apparent. Two hours after the bath, the same morbid fancies existed as before he entered it. He had doubts of his identity, and affirmed that he had not committed any crime. When asked regarding his business, he gave the required information with great precision but with much brevity, on account of his mind being distracted by imaginary accusing voices. He manifested no restless excitement, uttered no cries, and did not exhibit any spasmodic movements. For two days similar prolonged baths were continued; and, on the following day, he was again purged by Seidlitz water. Next night was much more calm; he slept two hours without awaking in a start.

"On the 9th of June, I found him walking in the garden. He was still somewhat disturbed in his mind, and asked me what would become of him if he could not see his father. He listened to me with more sustained attention than on previous occasions. He possessed a half consciousness of his state; in a vague way he felt that all was not right, but he did not know what was taking place around him. He had again a prolonged bath with the cold affusions. He dined in the evening with more appetite. During the night, he had five hours of tranquil sleep. On the 10th, I found him better. He still had depressing mental delusions; but he made inquiries regarding his family. His recollections were hazy, and he was not aware how long he had been in the establishment. I told him that he had had an illness resulting from alcoholic excesses. He admitted that he had been leading an irregular life, and that there had been a change for the worse in his habits. He still continued to be afraid of being arrested and put in prison. From the 10th to the 15th, the appetite and digestion became more and more natural, and the delirious fancies at the same time continuously decreased till he was considered cured. He left the asylum on the 25th June, quite re-established in health."

As Dr. Magnan remarks, the value of this case is enhanced by the subject having been of sober and regular habits till he took to *absinthe*-tippling a short time before his attack. In this respect, the clinical case partakes much of the nature of an experiment. In the man, the hallucinations and delirium did not manifest themselves for some days; whereas, in the dogs on which Dr. Magnan experimented, the dose of the poison was larger, the drug was the pure essence of wormwood, and not the liqueur which, in virtue of its alcohol, retards without preventing the action of the wormwood poison.

The second chapter is clinical. In it the author classifies the patients who are the subjects of alcoholic delirium, basing the classification upon the degree of poisoning, and the predisposition of the individual. This division supplies valuable rules of practice, particularly with respect to the necessity for and duration of confinement in an asylum. This chapter also contains clinical illustrations of the action of *absinthe*.

In the third chapter, we have an exposition of the symptoms and

diagnostic signs of febrile delirium tremens. This is an important question, and one which has proved embarrassing to many. The difficulty has been to establish a well marked difference between the formidable affection, febrile delirium tremens, and the comparatively mild affection, simple delirium tremens. On this subject there has hitherto been a want of agreement; and the conclusions deduced from statistics are flagrantly at variance as to the natural progress of the disease, its termination, and its modifications by treatment. This is not remarkable when we consider that the disease is so essentially polymorphic as often to lose the marks of its identity. When it coexists with other formidable diseases, as it often does, it may easily escape recognition, and so lead to errors in treatment. In febrile delirium tremens, "the fever", says Dr. Magnan, "is an essential element of the disease, and has an existence of its own. In the other form of delirium tremens, the fever has many sources, originating, as the case may be, in pneumonia, erysipelas, pericarditis, or traumatism, resulting from injuries or therapeutic appliances. According to the cause, so does the fever comport itself: in the one class of cases the fever follows the normal cycle; in the other, its progress varies with the progress of the intercurrent affection."

The indications of treatment in febrile delirium tremens are, according to the author: 1. To protect the patient from himself, and to prevent him from injuring others; 2. To favour the elimination of the poison; and, 3. To sustain and improve the strength of the patient. In treating the first indication, Dr. Magnan expresses himself strongly against the too great use of the strait waistcoat in France, which, he shows, is often the cause of serious pulmonary congestion. Touching the use of hydrate of chloral, the following sentences deserve attention.

"Let me add a word, a few words, regarding hydrate of chloral, the efficacy of which, in delirium tremens, has been so much lauded by some physicians as to be represented by them as almost the specific medicine for the disease. Unquestionably, chloral has its place in the treatment of mental diseases: it affords a very ameliorative repose in mania, and in melancholia accompanied by restlessness and insomnia; but it is only necessary to recollect the physiological properties of the medicine to reject its use in the acute forms of a kind of poisoning which itself exceedingly compromises the circulatory and respiratory functions. Moreover, on perusing the history of cases said to have been cured by hydrate of chloral, one very soon sees that they were not cases of febrile delirium tremens, but of simple alcoholic delirium."

The fourth chapter, which treats of chronic alcoholism, is highly original, and of great practical value. The author not only gives in his adhesion to the opinions of some former writers to the effect that the two terminations of chronic alcoholism are general paralysis and dementia, but he also extricates this subject from doubt and controversy. By a record of well observed cases and of most careful researches in pathological anatomy, he demonstrates the wherefore of the tendency to these terminations. In this chapter, also, we have a description of the hemianæsthetic form of chronic alcoholism which is accompanied by muscular debility, loss of general sensibility, and loss of special sensibility. This is to a great extent a new question, and is full of the highest interest in relation to the pathological physiology of the brain.

The fifth chapter is excellent, though it does not contain information of an original character. It is devoted to the consideration of those cases in which alcoholism is combined with different forms of mental disease. We would particularly call attention to important remarks in this chapter on the relation which alcoholism bears to dipsomania and general paralysis.

In commending this volume to our readers, we would particularly remark that it is rich in clinical information and therapeutic suggestions, suited to the emergencies which frequently arise in the practice of any general physician when he has to treat acute diseases and severe injuries in persons addicted to excessive alcoholic potations. The experiments on animals, as well as the observations made on living patients, and the examination of the bodies of those who have died, are all given in clear language and satisfying detail. The rules of practice may, as a whole, be said to rest on a secure foundation of facts.

A LUCID DESCRIPTION.—A hundred and fifty years ago, opium was highly prized as it is at present, but its action was so little understood that a noted author said of it, "when it is given in too great a quantity it so thickens and glues the humours in the brains, by its viscous parts, that the spirits which come forward to succour, not being able to dissolve this viscosity, are forced to stop and congeal likewise, by little and little, until at last they lose all their motion, whence it comes to pass that many do die upon the taking of opium".

SELECTIONS FROM JOURNALS.

SURGERY.

COMPRESSION IN HYDRARTHROSIS OF THE KNEE.—Dr. Maurice Langier (*France Médicale, and Irish Hospital Gazette*) directs attention to the success which has attended the treatment of this affection by the plan of compression adopted by M. F. Goyrand. Instead of applying the force directly to the whole knee, which is irksome and painful, he places the limb upon a splint, which only leaves the anterior part of the joint uncovered. Sheets of wadding are applied to the knee, and form a thick bed for it. The limb is then fixed by a bandage, which includes it in the splint. By this means, the compression is borne upon the anterior part of the knee, the posterior and lateral portions being protected by the splint. M. Langier selects two cases from many in which the result was satisfactory, a cure being effected in one instance in ten, and in the other twenty-three days.

LOSS OF AN ARM FROM DERMATO-CELLULITIS.—Dr. P. F. Eve (*American Medical Weekly*) reports a rare case, having the following points of interest. A healthy man, aged 67, was thrown, some nine years ago, from a mule, upon a rocky surface, striking the right forearm in the fall. For several weeks after the accident, he was unable to go about his farm. The inflammation then excited continued until 1873. At that time, there were several fistule on the anterior and posterior surface of the limb. The use of the right arm and hand was lost; there was neither flexion nor extension, pronation nor supination, nor could the hand or fingers be closed. The whole limb was rigid, incompressible and useless. A thick grumous matter, limited in quantity and inodorous, escaped from the sinuses. No diseased bone could be detected by the probe. The affection was due exclusively to the connective areolar tissue, the inflammation extending through the whole thickness of the subcutaneous connection. After every device had been tried in vain, the limb was amputated at the middle third of the arm. An examination of the separated limb showed that none of the articulations were specially affected, and that the bones were healthy. The entire soft parts were agglutinated, cellular tissue being removed by the disease, so as to allow no motion of the parts.

BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 13TH, 1875.

VERY HIGH TEMPERATURES.

THE extraordinary case of high temperature recorded by Mr. Teale of Scarborough, of which a notice appeared in last week's BRITISH MEDICAL JOURNAL, cannot but excite the attention of the whole medical profession; and, inasmuch as it tends to overturn all our notions regarding the effects of high temperature on the body, it must necessarily excite much criticism. When we have before us a large number of facts experimentally ascertained by numerous and careful observers and by various means of inquiry, all of which show that certain effects invariably follow a certain cause, we naturally hesitate before accepting any single observation which is in direct contradiction to all our previous ones. When we read of St. Denis, after decapitation, walking about with his head under his arm, we are naturally incredulous; for such an action would be a most notable exception to the rule, that a headless trunk is incapable of executing such complicated and definite movements, the most that it can do being only to give one or two convulsive kicks. And yet, why should not St. Denis walk about with his head under his arm? There are two reasons why he should not. Firstly, because we know, from cases of fracture of the spine, that a man's spinal cord cannot originate such movements as that of walking; and, secondly, because the body cannot live without blood, and the vital fluid would be quickly lost from the severed carotid and vertebral arteries. Clearly, then, an ordinary man cannot live without his head; but St. Denis may have differed in some slight par-

ticulars from other men. A duck can run about without a head; and, if St. Denis possessed a spinal cord resembling in some degree that of a duck, he might walk about without his head. If his carotids happened to possess much contractility, they might close up like small arteries and prevent any loss of blood, and so the body might walk about for a long time. It is not impossible that St. Denis did possess these two peculiarities in his spinal cord and arteries, and that, in consequence, he did walk about with his head under his arm; but we require very distinct evidence indeed to convince us that such was the fact.

Now, just as experience has shown that headless trunks do not walk, so has it hitherto shown that, when the temperature of the human body rises to 111 or 112 deg. Fahr., death invariably ensues. But a temperature of 104 deg. in man is accompanied by the symptoms of high fever, while it is normal in the rabbit, sheep, and ox, is below the normal of other mammals, such as the bat and the squirrel, and far below that of many birds. If the titmouse, finch, and swallow, have a normal temperature of 111 deg. Fahr., why should not cases occasionally occur where such a temperature in man should be present without any serious consequences? The only answer to this is, that, although we cannot fully give the why and the wherefore, yet experience shows us that the bodies of most men are not constructed to withstand this temperature, just as their spinal cords do not enable them to run like ducks after decapitation.

But, in Mr. Teale's case, we have not only a temperature remaining at upwards of 110 deg. Fahr. for weeks together, but we have it rising on several occasions to the astonishing height of 122 deg. Fahr., and probably even of 124 deg. Fahr., and yet the patient recovers. To understand what this statement involves, let us consider a few of the principal effects of high temperature on the various organs of the body. And firstly, the blood must have undergone great changes at a temperature of 122 deg. Fahr. The fibrin which forms the clot in coagulated blood does not exist in the living body any more than water exists in a jar full of oxygen and hydrogen. In living blood, there are two substances present—fibrinogen and fibrinoplastic substance; and the action of a ferment causes them to unite to form fibrin, just as the oxygen and hydrogen unite to form water when an electric spark is passed through them. But both the fibrinogen and fibrinoplastic substance become altered to such a degree when they are heated to more than 122 deg., that they altogether lose their power of combining to form fibrin. The muscles undergo still more noticeable changes: for, at a temperature of 120.2 deg. in mammals, and about 122 deg. in birds, they become coagulated, rigid, and stiff; so that, judging from experiments on this subject, any one would have said that life at 122 deg. Fahr. was a thing impossible, even for a bird, because the muscles would then be boiled in their own juices.

Nor is the heart likely to be exempt from the fate of the voluntary muscles, and to continue to pulsate after they have become rigid. The very reverse of this is the case, and the heart usually ceases to beat long before the temperature has risen so high as to affect the muscles. As the temperature rises, the cardiac pulsations become quicker and quicker, until at last they become merged in a sort of general shiver of the organ, which next becomes spasmodically contracted, and remains absolutely still in a state of tetanus. From this condition it may recover, if quickly cooled; but, if the temperature be raised even a little, instead of being lowered, the tetanus passes at once into rigor, and all hope of recovery vanishes. The effect of heat upon the heart is almost the same when the organ is removed from the body as when it is *in situ*; for Schelske, Cyon, and Panum have shown that the hearts of frogs and rabbits beat more rapidly, and then cease when they are warmed up, after they have been cut out from the body, just as they would do if they were still in it. This constant effect of heat upon the heart under conditions so very different naturally inclines us to look upon it as something which we may always expect, and to be still more astonished not only that the heart continued to act at all in Mr. Teale's case, but that the pulse did not rise above 100 when the

temperature was at 107 deg. Fahr., nor above 120 when the temperature rose to 122 deg. The respirations at 107 deg. were unaffected, a circumstance which is also contrary to all our previous notions. Not only has it been noticed that high temperature of the whole body produces accelerated respiration, but Fick and Goldstein have found that when the blood in the carotid arteries alone is warmed so as to warm the part of the brain which regulates the respiratory movements these movements become quicker just as the heart beats more rapidly when it is warmed. But, supposing that the muscles, heart, and respiratory nerves—to say nothing of the brain and other parts of the nervous system which in other persons lose their powers at such high temperatures—supposing that these were all different from those of ordinary persons in Mr. Teale's patient, the catalogue is not exhausted. For a long time after the temperature had risen to 122 deg. Fahr., the patient continued to eat and to digest more or less perfectly, otherwise she could not have survived. But pepsin and the active principles of the other digestive juices lose their activity about 113 deg. so that in an ordinary case a rise to temperature to 122 deg. would completely deprive them of all power, and render digestion impossible. It may be objected, that all these determinations of the effect of heat on blood, muscles, heart, respiratory apparatus, and digestive ferments, have been made on animals, and not on man. It is quite true that most, if not all, of these experiments have been made in this way; but it must be remembered that the animals on which they were made have normally a higher temperature than man, and that we might, therefore, expect that their tissues would bear at least as high a temperature, if not a higher one, than the tissues of the human body.

The difficulties raised by Mr. Teale's record are, therefore, exceedingly great; but, on the other hand, both Mr. Teale of Scarborough and Mr. Pridgin Teale of Leeds bear such a high character, both for honesty and accuracy, that every one who knows them would instantly scout with the utmost scorn the idea that the record is untrue; and very few can even imagine the possibility of their making a mistake. It is exceedingly difficult to reconcile their observations with the results obtained by others. The hot bottles which some one suggested have been most emphatically disclaimed by Mr. Teale, and one cannot see how pressure could have been applied to the bulb of the thermometer, so as to raise the mercury, without breaking the instrument.

Granting that Mr. Teale's observations are correct, almost the only way of reconciling them with what we know of the general effects of heat on the various organs, is to suppose that the development of heat was only local in the limbs, and that some alteration of the vaso-motor system prevented the superheated blood from reaching the heart, brain, and digestive system, and thus allowed the circulation, respiration, and digestion to go on with comparatively little disturbance. In order to account for the muscles remaining flexible and contractile, instead of becoming rigid and stiff, we must either suppose that human muscles resist heat better than those of animals, or adopt the most improbable hypothesis, that the heat was only in the skin, and that the muscles below were also protected by the contraction of vessels from the influence of the superheated blood. It is unfortunate that the temperature was not taken also in the mouth, but the observations given tend to show that there was some vaso-motor disturbance, rendering the distribution of heat more partial than usual. Thus the temperature was 116 deg. between the thighs, while it was only 113.5 deg. in the axilla, and sometimes, when the thermometrical readings were highest, the hands, feet, and forehead were icy cold. Whether this explanation be true or not, the case is one of extreme interest; is altogether unique, and is almost certain to give still further interest to the much debated subject of animal heat, its causes and consequences.

THE HOSPITAL SUNDAY FUND.

A PUBLIC meeting was held at the Mansion House on Monday last, to receive the report of the special subcommittee appointed on January

4th, and to determine the system of distribution for the current year. The Egyptian Hall was completely filled a quarter of an hour before the time of meeting. Of those present, a large proportion were young men whose appearance indicated that they belonged to the shopkeeper class, and for whose interest in the subject it was difficult to account. The proceedings were of a most uproarious character, such as have never before been witnessed at a Mansion House meeting. Dr. Morell Mackenzie took a leading part in the business of the day, and the violent opposition which his supporters made to the programme of the Fund Committee was such, that twice during the meeting the Lord Mayor was only able to restore order, and secure a hearing for the speakers, by threatening to leave the Chair.

Mr. Galsworthy moved, and the Rev. J. F. Kitto seconded, the adoption of the report, which stated at its commencement that, on January 20th, Dr. Morell Mackenzie was invited to present a system of distribution by way of amendment on the report of January 4th. Of fourteen propositions made by him, four had been withdrawn, six were not accepted, three were accepted as modifications of the system adopted at the last public meeting, and one was passed with slight amendment. Several additions and modifications made by the Committee appeared in the report, among which were: that special hospitals were entitled to participate in the fund on the same basis as general hospitals; that it should be left to the discretion of the Distribution Committee to deal with the contributions of patients in defining the basis of award, as they saw fit; and that in every case where the cost of management exceeded what the Committee of Distribution considered a reasonable percentage of the whole current expenditure, such excess should be deducted from the basis of award.

Sir Rutherford Alcock and Dr. Morell Mackenzie then rose at the same moment. Immediately a tempest of hooting and shouting commenced, with loud calls for "Mackenzie". But the Lord Mayor ruled that Sir Rutherford Alcock should speak first, and accordingly he endeavoured, amid repeated interruptions and frequent attempts to cough him down, to impress upon the meeting the responsibility which rested upon it in dealing with the distribution of so large a sum as £30,000 *per annum*. But his words were unheeded. The youths who followed fuglemen at various points, and who formed such a conspicuous element in the meeting, had evidently not come to listen to reason, but to exercise their voices by hooting down some speakers and cheering on others. It was now Dr. Morell Mackenzie's turn to speak, and he was greeted with tumultuous cheering. He said that he wished to move an amendment to the report, and his reason for doing so was that he thought that the committee was exceedingly unfairly constituted. There were actually only three members of it connected with the special hospitals, while there were nine belonging to the general hospitals. In giving instances of the way in which his scheme had been received by the Committee, he said that one of the members had had the coolness to raise the question as to whether the scheme should be considered at all. In reply to cries of "Name, name", he declined to give the name, because he felt sure the member was heartily ashamed of the course he had adopted. Another gentleman had described the meeting of January 4th, as being a "packed" meeting. He thought that that gentleman, too, was ashamed of himself. He passed to the scheme itself. Four of his propositions were stated to have been withdrawn, and the object of that statement was to show that his scheme was so incomplete that he was obliged to withdraw these four resolutions. That was not the case. Certain propositions were negatived, and he was obliged to withdraw, in consequence, others that he had brought forward in favour of justice and impartiality. At the first meeting there was simple wrangling. All they did was to negative his scheme; and, such being the case, he ventured to move an amendment, which he had put in the form of an abridged scheme of distribution.

The scheme proposed by Dr. Mackenzie was as follows:

1. The Committee, consisting of nine members, and the Lord Mayor as President *ex officio*, shall be elected at the first meeting of the Council after the annual public meeting.

2. No person holding office in a hospital or dispensary, whether it participates or not in the Hospital Sunday Fund, shall be eligible to serve on the Committee. This rule shall not apply to patrons, presidents, vice-presidents, or governors, as such.

3. The system of distribution shall be primarily based on the last three years' expenditure of each institution, after deducting from that amount a sum equal to the income derived from endowments, realised property, and legacies exceeding £100, but under no circumstances shall the contributions of patients be deducted from the basis of the award.

4. In all cases where the general expenses of management exceed 20 per cent. of the annual subscriptions and donations (not including the donations from the Hospital Sunday Fund), such excess shall be deducted from the primary basis of award, but in no case shall the primary basis of any institution be lowered, or any award withheld, until after a conference has been requested with the managers of the particular institution concerned.

5. Although no award shall be made on account of money collected for building funds or endowment funds, cost of management to the extent of 20 per cent. shall be allowed in connection with such funds, and the management expenses thus incurred shall be deducted before the general expenses of management are computed.

6. Special hospitals are entitled to participate in the fund on the same basis as general hospitals.

7. Incurable hospitals are entitled to participate in the fund on the same basis as general hospitals, but the basis shall be limited to the expenditure in connection with patients treated within the walls of such institutions.

8. That it be an instruction to the Committee of Distribution to place dispensaries on the same footing as hospitals as regards the general basis of award, and that only such dispensaries as are managed by a committee duly constituted be admitted to participate in the fund.

Dr. Mackenzie went on to say that his second proposition was a very important one, and would exclude all those medical men who had the management of the large endowed hospitals, and also the treasurers of those institutions. With regard to the fourth, the term "reasonable" adopted by the Committee was exceedingly vague and unsatisfactory. It then depended entirely on the views of the members of the Committee, and was one of those schemes which permitted favouritism and encouraged jobbery. The seventh resolution was intended to meet the clause of the Committee's rules which excluded the incurable hospitals. It was as though they said, "If you take a patient into a hospital, and he dies quickly, we will give him a grant; but if you keep him alive for a week or a month, we take the award away". He merely wished to add that he had brought his scheme forward in a spirit of conciliation. It was fair to the large hospitals and to the small hospitals; and he trusted it would be accepted in its integrity, as it was necessary for the continuance of the Hospital Sunday Fund.

Mr. Charles Hood (who is, we believe, the Chairman of the British Home for Incurables) seconded the amendment in a speech of remarkable feebleness. Sir Sydney Waterlow, who replied on behalf of the Committee, would have had no difficulty in answering the two previous speakers, if only he could have obtained a quiet hearing; but such was the noisy behaviour of a portion of the meeting, that even Sir Sydney Waterlow, to whom this movement owes more than to any other single individual, was not allowed to speak without frequent and most unseemly interruptions. Subsequently, Canon Miller, Mr. Octavius Coope, M.P., and others, attempted to speak; but their voices were almost inaudible, on account of the uproar and the cries of "Divide," "Divide". Dr. Mackenzie's amendment was then put by the Lord Mayor, and was carried by an overwhelming majority, amidst boisterous applause. The amendment was then made a substantive motion; and it was moved by Dr. Glover that the clause relating to the

exclusion of medical men from the Committee be omitted. Bishop Claughton supported the amendment, and was understood to say that he could not preach in favour of the fund if the guarantee for its distribution, which was afforded by the presence of the medical men, were withdrawn. The amendment was put and lost. Dr. Mackenzie's motion was then carried, and the proceedings concluded with three cheers for that gentleman and for the Lord Mayor.

We sincerely regret that such a movement as the Metropolitan Hospital Sunday should be endangered by such boisterous proceedings as those which characterised this meeting. We freely admit that a few of Dr. Morell Mackenzie's proposals were reasonable. Some of them had been already adopted and embodied in their report by the Fund Committee. Others might still be fairly considered open to discussion. But no discussion was allowed by the majority present. Anything like argument was silenced by hooting and noise. If there was "wrangling" at the Committee meetings, what word can describe the scene in the Egyptian Hall on Monday last? It called to mind the uproar at the hustings at a contested election before the passing of the Ballot Act.

The arguments of Dr. Mackenzie's speech might convince the general public, but with his professional brethren they will carry their own refutation. He says the Committee was unfairly constituted because nine members represented the general hospitals, and only three the special. But we imagine that our readers, who are acquainted with the relative value of these two classes of institutions, will mostly agree in thinking that the special hospitals were quite sufficiently represented. Again, it may be a question whether Homes for the Incurable should participate in the fund. They are, in truth, more like almshouses than hospitals; and, as Sir Sydney Waterlow pointed out, the fact that admission to them is obtained by the voting system gives them a different character. But it is hard to maintain that the difference is as if the Committee said—"If you take a patient into a hospital, and he die quickly, we will give him a grant; but if you keep him alive for a week or month, we take the award away." All who are acquainted with hospitals know full well that it is no uncommon thing for them to keep patients many weeks, or even months. The distinction between the two classes of institutions does not lie in this; and of this fact our readers must be well aware.

Again, the second proposition passes a very poor compliment on the profession. The distribution of the fund is a matter which closely concerns us, and upon which the experience of medical men must surely be of great value. It has always appeared to us a source of satisfaction that, from the fact of the great endowed hospitals not participating in the awards, it was possible to obtain from their staff men of high position and character to assist at the deliberations of the Distribution Committee. But now, thanks to Dr. Morell Mackenzie, we are to be deprived of our representatives. We can hardly doubt that many clergymen will agree with Bishop Claughton in hesitating to preach for the fund "if the guarantee for its distribution, which was afforded by the presence of the medical men, be withdrawn".

We cannot believe that the public will be contented to accept the decisions of such a disorderly meeting as this. It will give as little satisfaction to them as it does to the profession. The matter can hardly be allowed to rest here. It will be asked and asked with very good reason—Of whom did the meeting consist? Who composed the majority? What gave rise to their irrepressible enthusiasm? What practical knowledge had they of hospitals, or what proof had they given of their interest in them? These questions will naturally suggest themselves, and the public will probably demand that Monday's proceeding should be reconsidered; and that, at any future meeting called to deliberate upon the Hospital Sunday, means shall be taken to limit the admissions to those who have given substantial proof of their interest in hospitals and dispensaries, and who may, therefore, be expected to conduct themselves in an orderly manner when questions affecting those

institutions are under discussion. Unless some such steps be taken, there is reason to fear that the whole movement will be discredited. Another such meeting as Monday's would go far to make shipwreck of a good cause.

MR. SERJEANT COX presided at a meeting last week, when it was resolved to form a society for the promotion of Psychological Science, under the title of "The Psychological Society of Great Britain". T. K. Munton, Esq., was elected honorary secretary.

MESSES. MACMILLAN will publish shortly "A Course of Practical Instruction in Elementary Biology", by Professor Huxley, F.R.S., assisted by H. N. Martin, B.A., D.Sc., of Christ's College Cambridge.

THE current number of the *Fortnightly Review* contains two articles on subjects of medical interest: Vivisection, by Mr. E. Congreve and Dr. J. H. Bridges; and the Practice of Medicine by Women, by Miss Jex-Blake. Both articles are worth reading.

THE sum collected at Liverpool on January 10th, and January 16th, which were set apart as Hospital Sunday and Saturday, and the joint receipts, being merged into one fund, was £9,300. This amount was £1,500 less than was realised last year. The falling off is attributed to the fact that the late Mr. Lyon Jones had left the sum of £350,000 to be divided among the various benevolent institutions of the town.

THE London correspondent of the *Scotsman* writes: So far as can be at present arranged, the motion for going into committee on the Artisans' Dwellings Bill will be taken some time next Thursday, but only with the object of getting rid of the talk. As soon as the motions on the measure are got rid of, the actual committee work will be postponed till the following Thursday. There are three pages of notices.

THE Government of Madras on January 11th, issued its general orders on the admission of lady students to the Madras Medical College, and on the course of study to be pursued. The *Eastern Chronicle* (Madras) announces that lady aspirants to medical honours will now be able to study for the degree M.D., if they determine to do so.

A PROVIDENT HOSPITAL FOR BRIGHTON.

AN important meeting was lately held in the Town Hall, Brighton, with a view to the establishment of a provident hospital. It was summoned by a circular, which stated that "by the establishment of such an institution, the prevalent abuses connected with our medical charities will be to a considerable extent prevented, while a stimulus will be given to thrift and self-dependence among a large section of our population". All the speakers were unanimous in saying that they did not wish to injure any existing institution, and that if another hospital were started, it should not be charitable, but entirely self-supporting. The necessity for something of the kind was shown by the fact which was mentioned, that "one-fourth of the population of Brighton were receiving medical relief of a gratuitous kind, and it was surely time that some steps were taken to prevent this state of things". It was also urged by several speakers, "that something was due to the medical staff. There was no profession which was so shamefully abused as theirs, and it was high time that these abuses should be remedied. It was the wish of the promoters of the scheme that the medical officers should be paid for their services. They should consider not only the cost of the maintenance of patients, but also the remuneration due for medical attendance. Otherwise they would continue to be relieving the pockets of the wealthy at the expense of the medical men". The question was raised whether it might not be possible for the Sussex County Hospital to take up the proposal, more particularly as a similar plan was at present under the consideration of the managers of that institution. Ultimately it was decided

that the whole matter should be referred to a committee, to report to a future meeting upon the expediency and practicability of establishing a provident hospital, and to lay before it a detailed scheme for such an institution.

MANSLAUGHTER BY INFECTION.

WE publish to-day in another column the report of the criminal prosecution of another midwife for causing the death of certain lying-in women, to whom she is alleged to have conveyed the contagion of puerperal fever. Mrs. Ingram, whose trial we last week reported, had been cautioned by a police inspector; Elizabeth Marsden appears to have been cautioned by a surgeon. The precedent is a very stringent one, and, as we pointed out before, if manslaughter by infection became an offence readily recognised and habitually punished by criminal prosecution and conviction, it will undoubtedly behove all medical practitioners, as well as midwives, to move with very great caution; and, unless such prosecutions be regarded with some jealousy, and a sincere regard to all the related facts and consequences, the perils of professional practice will be very largely increased. The prosecution of midwives appears to take place amidst considerable applause; nor ought they to escape any penalty which justly attaches to ignorance or neglect. It is obvious, however, as we pointed out from the first, that the arbitrary principle involved does not concern midwives only. The editor of the *Edinburgh Medical Journal*, commenting on the case of Mrs. Ingram (as reported in the coroner's investigations), illustrates his views thus:—"Down comes the policeman to Sir William Jenner, to tell him to see no more cases of croup for two months, at his peril, as the coroner hears he has been attending some fatal cases; to Sir William Gull, to give up practice for two months, as he hears he has been attending some fatal cases of scarlatina; to Dr. Farre, to give up practice, because he has been in repeated consultation in a fatal puerperal case; to Sir J. Paget, to give up operating, as he is in attendance on a case of erysipelas; and so on." In these days, when the extent to which diseases are influenced by septic germs and hospital influence is much debated, the vista opened up by such prosecutions leads a long way, and is lost in a rather obscure shade.

POISONING BY HOMŒOPATHIC SOLUTION OF CAMPHOR.

THE subject of poisoning by the homœopathic concentrated solution of camphor, to which the attention of the profession was first called by Dr. George Johnson's paper in the *Clinical Society's Transactions*, has during the last few days excited a more wide-spread interest in consequence of the *Times* having published on the 5th instant a letter by "A Physician", the object of which was to warn the public of the danger which is incurred by the incautious use of this concentrated poison. In Dr. Johnson's paper, five cases of poisoning by this strong solution of camphor are recorded; and four have been recently published in our columns. The slighter symptoms have been giddiness, faintness, headache, and drowsiness; but, in five out of the nine cases, a dose ranging from fifteen drops to a teaspoonful caused epileptic convulsions, and more or less profound and alarming stupor; and it is probable that death would have resulted in more than one instance, if a large proportion of the poison had not been speedily ejected by vomiting. The symptoms described are those which are well known to result from an overdose of camphor. Nevertheless, Dr. Bree, in a letter which appeared in the *Times* on the 6th instant, expressed a doubt whether camphor was really the cause of the symptoms, and gave as a reason for his doubt, that he had taken camphor in three-grain doses with no other than a beneficial effect. He had prescribed it for others in much larger doses; and "in the *British Pharmacopœia* the dose is given as from one to ten grains, or what is equal to from two to twenty drops of the homœopathic solution". Dr. Bree's letter was promptly answered by "A Physician" and by Prince Louis-Lucien Bonaparte, both of whom pointed out that Dr. Bree's error consisted in comparing camphor in the solid and dry state with camphor dissolved in spirit. It is a well known fact that the action of

a poison is, *ceteris paribus*, in direct proportion to its solubility. Camphor, being very insoluble in the fluids of the alimentary canal when given in the form of a dry solid, is in great part eliminated without being absorbed, and has little medicinal or poisonous effect; but, when taken in the form of a spirituous solution, it is much more readily absorbed, and in a corresponding degree more active. The compilers of the *Pharmacopœia* apparently consider that camphor dissolved in spirit is at least three times as active as solid camphor; for, the dose of the latter being from one to ten grains, that of the spirit of camphor, which contains one grain of camphor in ten minims, is given as from ten to thirty minims. We have, then, no difficulty in understanding that this saturated solution of camphor, which contains about a grain of camphor in every two drops, should, in any dose above five drops, cause unpleasant symptoms; and that, in doses of fifteen drops and upwards, it should act as a strong poison. If the public could be made to understand that modern homœopaths have gone from the harmless extreme of infinitesimal dilution to the dangerous extreme of the greatest possible concentration of active and poisonous drugs, they would be more cautious in playing with these dangerous weapons. This homœopathic solution of camphor is as actively poisonous, drop for drop, as the prussic acid of the *Pharmacopœia*; and we maintain that any chemist who sells it without labelling it as "poison" should be as liable to censure and to penal consequences as if he sold prussic acid, or the much less powerful laudanum, without a "poison" label.

ROYAL COLLEGE OF PHYSICIANS.

THE Lumleian Lectures will be delivered by Dr. Lionel S. Beale, On Life, and on Vital Action in Health and Disease. The following is the argument. Lecture I—Friday, March 12th, 5 P.M.: Objections to Physical Doctrines of Life; of Living Matter, or Bioplasm, and of Formed Material; Simplest Form of Living Matter: Bioplasm of Bacterium; Living Matter Structureless; of Vital Movements, peculiar to Living Matter. Lecture II—Wednesday, March 17th, 5 P.M.: Of the constitution of Living Matter; Question of the Origin of Life; Absolute distinction between the Living and the Non-living; of the construction of the Body by Bioplasm. Lecture III—Friday, March 19th, 5 P.M.: Construction by Bioplasm continued; Bioplasm in Disease; the degradation of Bioplasm; Disease Germs; the highest form of Vital Action; Bioplasm of Nerve Tissue; Bioplasm of the Brain; Mind and Vital Power. They will be published in our columns.

THE BRADFORD INFIRMARY AND ITS MEDICAL OFFICERS.

WE learn from the local paper, that Mr. Semon has issued a circular to the governors and subscribers of the Bradford Infirmary regarding the proposed changes in the rules relating to the medical officers of the infirmary. He points out that, since the resignation, in 1845, of Dr. Outhwaite, the infirmary has been more or less deprived of the services of two physicians, that this has placed the Board in no small difficulty, and obliged it more than once to call in the paid aid of general practitioners. At present, the entire charge of the medical cases is thrown upon Dr. Alexander; and while the four honorary surgeons in 1874 had to attend to about 370 to 480 out-patients each, those under the charge of Dr. Alexander were upwards of 2,640, independently of which, Dr. Alexander had his own private practice to attend to, and, as physician to the Fever Hospital, had part of the patients there to attend. Mr. Semon suggests a reconsideration of the proposal to allow general practitioners to be appointed to take charge of the medical cases in connection with the infirmary. We understand that in connection with this, a circular was addressed to the medical practitioners of Bradford, asking their opinion in the matter. The replies sent in, it is stated, show that, with the exception of six or seven, the profession is in favour of the change.

THE CASE OF MISS WOODS.

SOME misapprehension may very readily arise, and, we believe, has arisen, as to the statement of the Home Secretary concerning the release of Miss Woods, who was recently placed under restraint as being

a certified lunatic, or person of unsound mind. We have authority for stating that Miss Woods was released on the ground of the informality of the certificates. The law properly surrounds the detention of alleged lunatics with very great safeguards; and in this case, as the required forms had not been properly complied with, release followed as a matter of course. The release did not imply any judgment by the Commissioners of Lunacy on any other facts of the case.

TEST-QUESTIONS.

SOME "Anti-Vaccination" delegates recently waited upon a candidate for the House of Commons, and asked him whether, if they voted for him, he would support the repeal of the Compulsory Vaccination Act. His answer was, "If you will only vote for me to-morrow, you may all get the small-pox the next day if you like". The answer was not considered perfectly satisfactory.

PROPORTION OF INQUEST-CASES.

It is safe to assert that there would be more danger to the community from too few inquests being held, than from their needless multiplication. The condition of life in England, however, has so completely changed since the office of coroner was instituted and the statutes regulating it became law, that, apart from the recent so-called "inquest-scandal", it has become a moot question whether a good many unnecessary inquests are not now held. Blackstone says that the office of the coroner consists mainly "in inquiring, when any person is slain, or dies suddenly or in prison, concerning the death". The object of the inquest was undoubtedly to discover crime, with the object of punishing it, and with a view to its prevention. A few centuries ago, when the state of science was far different from what it is now, "sudden death" was considered a sufficient ground for the holding of an inquest. Dr. W. Farr, in a letter on the causes of death in 1872, published in the last Annual Report of the Registrar-General, says: "The mere fact that death is sudden is a ground for medical inspection, but not necessarily for an inquest; and there are many violent deaths of which a medical inspection may ascertain the cause without moving the apparatus of the inquest, there being no more suspicion of crime in such cases than there is in deaths from fever, pleurisy, or consumption." In 1872, the number of inquests held in England and Wales was 25,705, at a cost of £78,535, or rather more than £3 per inquest. The general proportion of inquest-cases to total deaths has exceeded 5 per cent. in each of the three last years, 1872-3-4. It appears, therefore, that an inquest is held in one of every twenty deaths that occur. The proportion of inquests held varies, however, in different parts of the country, to an extent which makes it impossible to avoid one of two conclusions: either a large number of unnecessary inquests are held in some places, or the safety of society is being endangered by far too few being held in others. In support of this argument, we cannot do better than call attention to the proportion of inquests held in the eighteen large English towns for which weekly returns are published by the Registrar-General. In these eighteen towns, the percentage of inquest-cases to total deaths during 1874 ranged from 3.3 and 3.6 in Bradford and Hull, to 7.2, 7.6, and 7.9 respectively, in London, Birmingham, and Manchester. The average proportion in the eighteen towns was 6.3 per cent., whereas in the whole of England and Wales it was rather more than 5 per cent. It is natural that the proportion of inquest-cases in towns should exceed that in rural districts, in consequence of the greater frequency of deaths from violence; but this will not explain the wide difference in the proportion of inquest-cases in the large towns above mentioned. In Bradford and Hull, the percentage of inquest-cases exceeded that of deaths from violence by only 0.8 and 0.5; whereas in London the deaths from violence were 3.6, and the inquest, 7.2 per cent.; in Birmingham, 4.1 and 7.0; and in Manchester the violent deaths were 3.1, and the inquest-cases 7.9 per cent. Assuming that inquests are held in all cases of death from violence, in each 79 inquest-cases in Manchester, the cause of death in 48 was other than violence; whereas, of 72 inquest-cases in Hull, only 10 proved to be

deaths from natural causes. The question to be answered is, Are too many inquests held in Manchester, or too few in Hull? Such an anomalous state of things as to the proportion of inquests held is decidedly undesirable; and it would be well if some code of regulations could be drawn up, or law enacted, to secure greater uniformity of system among coroners, without detracting from the dignity and independence of the office by too far weakening its discretionary power. In counting the cost of inquests, the value of the time of the twelve jurymen summoned to each inquest, which is not paid for, should not be lost sight of.

THE ARTISANS' DWELLINGS BILL.

MR. JOHN LIDDLE, Medical Officer of Health for the Whitechapel District, in his Quarterly Report, whilst generally approving of Mr. Cross's Bill, regrets that it does not contain a clause requiring proper sanitary inspection to be made of the houses which may be erected in lieu of those pulled down. To make the Bill perfect, Mr. Liddle suggests the following amendments.

"1. Before the building of any new house is commenced, plans of the drainage, and of all the sanitary arrangements of the house, shall be submitted for approval to the Local Board. This Board shall be invested with power to compel the builder of any new house within the district so to alter his plans, if necessary, as to render such house fit for healthy occupation.

"2. It shall likewise be made compulsory on every builder to provide a separate water-closet or privy and ashpit for each house, within the curtilage of the house. This provision would prevent the erection of public privies in courts occupied by the poorer classes, which are now for the most part nuisances, and injurious to the public health.

"3. During the progress of the building of any house, the Surveyor to the Local Board shall be required to inspect the foundation thereof; and, if such surveyor be of opinion that the materials which are being used for such foundation are not proper for the purpose, he shall make known his objection to the builder, and shall report the same to the Board. This report having been made, the Board shall have power to prevent the use of all such improper materials.

"4. The walls and foundation of every house shall be so constructed as to prevent the rise of damp.

"5. Every new house shall at all times have at the rear an open space of sufficient extent for the thorough ventilation of the staircases and passages. No house shall be permitted to be occupied unless the person letting such house shall have a certificate, signed by the Surveyor and Medical Officer of Health to the Local Board, that all the rooms therein are of sufficient size and fit for healthy occupation."

THE COLORADO BEETLE.

DR. GEORGE LAWSON, Professor of Chemistry in Dalhousie College, Halifax, Nova Scotia, writes to the *Times*:

The German and Belgian Governments having enacted a decree forbidding the importation of "American potatoes," as a preventive measure against the much dreaded "Colorado bug," please permit me to state that the pest is quite unknown in the Province of Nova Scotia, so that there need be no fear of its being carried to Europe with any of our produce. Our summer climate appears to be too cool and moist for that and several other insects that are troublesome in inland regions on the same parallel of latitude. For a similar reason, I do not think that there is any great likelihood of the Colorado bug establishing itself permanently in the British Isles. In the hotter parts of Europe, away from the sea, suitable conditions may be found. I know for a fact that, for the last two or three years, numbers of Colorado beetles have been sent to England in produce from parts of this continent where, in the fall of the year, it is simply impossible to pack up any kind of produce without their getting into it; yet we do not hear that they have thriven anywhere in England. A hot and dry continental climate seems to be necessary for their development. The cold in winter, however severe, does not necessarily affect insects, which are then dormant. As in the case of annual plants, their possibility of existence depends upon the degree and continuance of summer heat.

WIGAN MEDICAL SOCIETY.

At a meeting of the medical practitioners of Wigan and the surrounding districts on Thursday, March 4th, it was resolved to form a medical society, having for its objects the mutual interchange of ideas, discussion of cases, reading of papers, and the consideration of medico-ethical

subjects. The following gentlemen were elected office bearers for the ensuing year. *President*, J. White, Esq.; *Vice-President*, C. D. Shepherd, Esq.; *Committee*, Messrs. E. H. Monks, W. Hart, and R. S. Hall; *Honorary Secretary and Treasurer*, Mr. Wm. Berry.

PROFESSIONAL PRIVILEGE.

AN interesting point, as to which much misapprehension prevails, was raised and settled in accordance with precedent this week in the Court for Divorce and Matrimonial Causes. In the case of *Babbage v. Babbage* (the Queen's Proctor intervening), several witnesses were called in support of the charges, among them a medical gentleman in practice at Bridgewater, to whom the petitioner addressed two letters, one of which was of a particular character, some time after the decree *nisi* was pronounced in the suit. The witness declined, on the ground of professional confidence, to produce the letters or divulge their contents. His Lordship said that he knew of no such privilege as that claimed by the witness. He respected the feeling which prompted the witness not to make known what was communicated to him by a patient until compelled to do so in a Court of Justice, but he was bound to produce or state the contents of the letters. The witness then deposed that he had destroyed the letters. The second he did not answer. It was of a peculiar character, and amounted to a confession of misconduct by the petitioner.

SCOTLAND.

ROYAL EDINBURGH ASYLUM.

THE annual report of the Royal Edinburgh Asylum has just been published, and is a most able and exhaustive paper. The following facts which are brought out in it, are of general interest. The average number of patients resident during the year was 738. The number of admissions (308) has been 14 per cent. above the average for the previous ten years, and this has taken place equally in the private and in the rate-supported classes of patients. Of these patients only six, an unprecedentedly small number, were from places other than those having a right of presentation, viz., Edinburgh, Leith, and Orkney. There has been a steady increase from year to year in the number of patients admitted from these parishes, from 134 in 1864, to 176 in 1873, and last year it ran up suddenly to 214, a figure higher by twenty-six than ever occurred before. Dr. Clouston was at first inclined to attribute this sudden increase to the 4s. 6d. a week promised by the Government towards the maintenance of each pauper lunatic, in the same way as happened in England after the passing of the Union Chargeability Act, but this did not seem sufficient to account for it all. Again, 47 per cent. of all the patients admitted were sent in within a month from the beginning of their illness, instead of 36 per cent., the average of the past ten years. This increase was further shown to be in cases of severity, while the number of milder forms admitted was but little higher than the average; and the districts to which the increase was almost exclusively due were found to be the two parishes of Edinburgh proper, the Leith parishes remaining at about the average. This relation to districts is only true of the rate-supported patients, the private ones coming from very various localities. Another striking feature is that, under the head of Melancholia, the number admitted was 88, or 70 per cent. in excess of the average of the past five years; many of these cases being desperately suicidal. The percentage of recoveries on the admission was forty-eight, the average of the year 1873 for Scotch asylums being forty-two. In point of death-rate, the first year has been the healthiest year in the history of the asylum, the deaths having been only 7.7 per cent. of the average numbers resident, and 5.4 per cent. on the total number of persons under treatment; not one of the deaths during the late severe weather, in November and December, being due to any catarrhal affection. The report concludes with a general review of the present state of the institution. With regard to the most striking feature of this report, namely, the great increase in the number of patients from Edinburgh, and the fact that that

increase was mostly due to acute cases and of the class of melancholia, there is some reason for connecting it with the great wave of religious excitement and revivalism which passed over the city last spring. We hear from other sources that the number of cases of insanity among the better classes, due to this cause, was very remarkable.

THE EDINBURGH ROYAL INFIRMARY.

At a meeting of the managers of the Royal Infirmary, held last week, it was intimated that a sum of almost £20,000 had been paid to the treasurer as part of the bequest of the late Mr. Thomas Grindlay, which, it is anticipated will ultimately amount to in all about £38,000. As an acknowledgment of this splendid bequest, the managers have determined that one of the wards in the new infirmary shall be called "the Grindlay Ward". A slight hitch has, it is said, occurred with regard to the agreement arrived at between the managers and town authorities, with reference to the drainage question, which had been arranged on the basis that no sewage from the fever wards should be passed into the drain until it had been thoroughly disinfected to the satisfaction of the Town Council. The London agent of the latter, in drafting a new clause for the Infirmary Bill, which is to come before the select committee of the House of Lords this week, has made the prohibition to extend to sewage of infectious diseases generally; to which alteration it is probable the infirmary authorities will not agree. It seems likely that the matter will not be pressed by the city authorities.

ADULTERATION OF MILK.

DR. STEVENSON MACADAM made an interesting contribution to the adulteration of milk question, on the 5th instant, in a paper read before the Pharmaceutical Society of Edinburgh. He said that last year he had procured specimens of milk from one of the best farms on the Tweed, where the pasture was luxurious, and he found the average composition of the milk yielded by the whole of the cows on the farm in a single day was as follows: Specific gravity, 1032.2; total solids, 12.77 per cent.; solids (not fat), 9.89 per cent.; fat or butter, 2.88 per cent.; ash, 0.71 per cent. Only two of the samples out of the whole dairy yielded the amount of fat which has been assumed as the standard quantity by city analysts, and on which prosecutions have taken place. Taking the average amount of fat, the whole runnings of this dairy would have been declared, by these analysts to have consisted of 90 per cent. of standard milk and 10 per cent. of skimmed milk; while the milk of the cow which yielded the lowest amount of fat (1.84 per cent.) would have been declared to consist of 57.5 per cent. of standard milk, and 42.5 of skimmed milk. These investigations showed that the high standard assumed by city analysts was actually above that of an excellent country dairy, taking either the whole runnings of the dairy, or the milk of certain individual cows.

LIGATURE OF THE COMMON CAROTID FOR ANEURISM OF THE INNOMINATE ARTERY.

ON Monday, Mr. Annandale tied the common carotid artery, at the Royal Infirmary, in a case of very large aneurism of the innominate; the size of the aneurism, and the consequent disturbance of parts, preventing the subclavian from being tied at the same time. It had been found before the operation that pressure on the carotid diminished the pulsation in the tumour to a very considerable extent, and after the operation the patient had lost the throbbing sensations, and felt much relieved.

REMOVAL OF GOITRE: PREVIOUS LIGATURE OF ARTERIES.

ON Saturday the 6th instant, Mr. Lister removed a goitre from a young woman, by the method first adopted, we believe, by Dr. Heron Watson; namely, the four principal arteries of supply to the thyroid are tied through a central incision before the operation of removal is attempted. This has been found most effectual in restraining the hæmorrhage, which, without this precaution, is so serious a drawback to the operation. The patient is doing very well.

DEATH-RATE IN THE WESTERN ISLANDS.

THE death-rate of the Western Islands for the early weeks of the present year has been very remarkable. In January, it was quite unprecedented. Out of a population of about 10,000, in the parish of Stornoway, the death-rate for that month was 60, which, after deducting seven accidental deaths, is equal to an annual mortality of 75 per 1,000. During the second week of that month the rate was as high as 130 per 1,000; this week was, however, exceptional, for, in the next two weeks, the deaths were reduced considerably. While the deaths were so numerous, only 26 births were recorded. In February, the rate had fallen to 25 per 1,000. A woman, named Catherine Macleod, died at Bayble, about nine miles from Stornoway, at the advanced age of 106 years. Her age, it is said, can be very clearly proved.

TYPHOID FEVER AND MILK.

AN outbreak of typhoid fever has occurred at Crosshill, N.B., the infection being conveyed by means of milk taken from infected farms. The local authorities have taken prompt measures to stamp out the epidemic, and enjoin dealers in milk to be careful not to receive any from farms on which this disease is or has been recently. As a further precaution, they recommend that all the milk used by the inhabitants should be brought to boiling point, as there are reasonable grounds for believing that this simple measure would obviate any risk which might arise, should any milk happen yet to be brought from infected farms.

IRELAND.

MR. JOHN HAMILTON, Surgeon to the Richmond Hospital, has been appointed Surgeon in Ordinary to the Queen in Ireland.

THE governors of the Rotundo Hospital have followed the good example set by the University, and elected Professor Colles to be consultant-surgeon, in the room of the late Mr. Adams.

TYPHUS fever of a bad type exists in the neighbourhood of Ballycastle Mayo, and has continued for several months without any appreciable cessation. Several medical practitioners have been attacked; one of whom has died, and two others have been prostrated from its effects.

SHELTER FOR CABMEN.

A COMMITTEE is being formed to take the necessary steps to introduce into Dublin the shelters for cabmen which have proved so successful in London and elsewhere. They can be erected for about £70 each, and provide rest, shelter, fire, and the means of cooking food, etc. In a sanitary point of view these huts are most desirable, and on temperance grounds a good deal may be said in their favour, counteracting, as they undoubtedly must, the temptation for alcoholic fluids, which cabmen especially at night, are, from the nature of their avocation so peculiarly exposed to.

EXTENSION OF THE BUILDINGS OF THE ROYAL COLLEGE OF SURGEONS.

It is proposed to extend the buildings of the Royal College of Surgeons of Ireland. The museums and library of the College have far outgrown the available space, and accordingly the Council has advertised for plans for the extension of the buildings. A considerable number of plans have been submitted, and we understand the architects differ as widely in their opinions upon this architectural operation as any of their employers ever did over a surgical one. The frequent alterations which have already taken place, while very judiciously executed in themselves, have left almost insuperable difficulties in the way of future improvements. Some architects have proposed something little short of demolition and reconstruction; but we believe the plan most in favour will consist in the simple extension backwards, with slight alteration of the present museums and library

KILMAINHAM GAOL.

By Dr. Thornhill's death, the vacancy of Surgeon to the County Dublin Prison has occurred, and the Board of Superintendence, in whose hands the appointment lies, will, on the 18th instant, proceed to fill it up. The salary attached to the post is £100 *per annum*, and the candidates already in the field are so numerous that it would be absurd to form the faintest idea who may be Dr. Thornhill's successor.

THE OPHTHALMIC HOSPITAL, BELFAST.

THE annual meeting of the friends of this institution was held on the 4th instant, and, from the report of the committee, we find that during the year ending February 17th, 1,143 new cases were under treatment, and the attendances numbered about 6,000. Of these 1,143, there were 817 ophthalmic cases, and 231 of aural disease, attended to at the extern portion of the hospital, whilst 95 were received into the case wards. During the year, several medical gentlemen and students attended the practice of the hospital, the only one of its kind, so far as we are aware, that exists in Belfast. Although the expenditure for the past year was less than the income of the hospital, yet the committee trust that there may be a hearty response to their appeal for further support, in order to thoroughly develop the means at their disposal.

DISPENSARY DOCTORS: A GRIEVANCE.

THIS week it is the intention of Mr. Bentley, a Poor-law guardian of the North Dublin Union, to move a resolution at a meeting of the members of that Board, to relieve medical officers from gratuitous attendance on parties of sufficient position in life to admit of their bearing their own medical expenses. The injustice is a glaring one, and very harassing to the medical officer; indeed, any one who has ever served as a dispensary doctor must, time after time, have suffered from annoyances of this kind. He may complain, and bring the matter before the dispensary committee, but will obtain no redress; the visiting ticket is cancelled occasionally it is true, but there is no check on the guardian who gave it, and he can issue a fresh one next day should he so desire. Some guardians will never refuse a visiting ticket, no matter what the circumstances and position of the applicant may be, and the only feasible plan, in our opinion, to check this practice, is that the guardian who issues a visiting ticket to a party who ought not to be relieved by the Poor-law medical system, should either pay for that medical attendance himself, or be prevented for the future from giving orders for gratuitous medical relief.

PROFESSOR COLLES.

THE appointment of Mr. William Colles to the Regius Professorship of Surgery in the University of Dublin has met with universal approval, both in and out of the profession, and especially among the members of the Medical Faculty of the University. Mr. Colles commenced his professional career in 1832 as house-surgeon to Dr. Stevens's Hospital, in succession to Mr. Cusack. On the retirement of Mr. Abraham Colles from the surgery to Stevens's, the present professor was elected as his father's successor. Mr. Colles quickly attained to eminence in his profession, and has contributed numerous and valuable papers on many branches of surgery to the Dublin medical journals. In 1864, Mr. Colles was elected President of the Royal College of Surgeons in Ireland. When the medical school of Stevens's Hospital was opened twelve years ago, Mr. Colles was elected lecturer on surgery in that institution. The extreme originality of his systematic and clinical lectures have gained for him great popularity as a teacher. As Regius Professor in the University, Mr. Colles becomes consulting-surgeon to Sir Patrick Dun's Hospital, which, as most of our Irish readers are aware, is an institution intimately connected with the University School of Medicine. Mr. Colles's appointment in the University will not necessitate the severance of his connection with his old friends at Stevens's Hospital, which institution, in spite of its long roll of eminent names, could ill afford to lose that of Colles, which has so long adorned it.

THE TREATMENT OF DIPSO MANIACS.

AN important meeting was held at Willis's Rooms, King Street, St. James's, on Thursday, February 11th, to consider the desirability of providing a home for dipsomaniacs of the upper and middle classes. The movement is now being carried out by Mr. Carsten Holthouse, of George Street, Hanover Square, as a preliminary step, and one which shows the feeling of some of the leading members of the profession, whose names were attached; the following certificate was read: "We, the undersigned, fully alive to the prevalence of this disease, and to the great want of an institution specially devoted to its treatment, are of opinion that such an one as you propose—which shall afford to its inmates the comforts of a home and the pleasures of society, while at the same time they are protected from temptation—would be a great boon both to the patients and to their families, and is well entitled to our recommendation and support. George Burrows, M.D., F.R.S., President of the Royal College of Physicians; Thomas Watson, M.D.; Charles J. B. Williams, M.D., F.R.S., President of the Royal Medical and Chirurgical Society; William Jenner, M.D.; William W. Gull, M.D.; J. Russell Reynolds; C. B. Radcliffe; Henry Monro, M.D.; William Wood, M.D.; H. Maudsley; G. Fielding Blandford, M.D.; William Fergusson; James Paget; Prescott Hewett; Henry Thompson." Subscriptions to the amount of £1,600 had been received, besides many promises of support. The Earl of Shaftesbury, K.G., presided.

Mr. HOLTHOUSE, after referring to letters he had received, said: I have every reason to know, that a very large amount of good might be achieved by such an institution as that which is now proposed; that is, that the patients should be admitted voluntarily, and should receive hospital treatment. We must look upon it that the patients more or less labour under disease. The digestive organs are out of order. They are frequently bordering on a state of delirium tremens, and generally require at the outset a considerable amount of medical treatment; that which would be adopted being one having special reference to their bodily condition. It is of very little use doing anything with these patients until you may say they have got the alcohol out of them, and are in a comparatively sane state. It is then that moral and religious teaching should be brought to bear, and that good results in that direction can be had. The first treatment is that which must have reference to the body. I propose that it should also be a home, whilst it answers the purpose of a hospital—a home for those unfortunates, who having, by their habits, separated themselves from their friends, relatives, and connections, are, to a certain extent, the outcasts of society. It should be to them a refuge and place of retreat where they might, in fact, pass a large part of their lives. I am quite certain that, among this class, certain individuals could be completely recovered from the habit. There are others again, who, though only incompletely recovered, in this way, that if exposed to temptation they fall, might be restored to a state of health which they would not otherwise enjoy, and have this place as a retreat in case of relapse. Many persons would be thankful to go to an institute of this kind, and place themselves under the slight restraints which are necessary to keep them in a continued state of health. It has been said, "You cannot detain these patients, you won't be able to keep them a month". There is no doubt that there will be difficulty, and this will always happen in the first month of the residence of the patients. It is then that the utmost care is required. The mode in which I propose to meet the want of legal power of restraint is, in the first place, a rule that each patient should pay in advance for, we will say, three months. Amongst the rules would be restrictions as to bounds and strict supervision. There would be resident officers, medical and clerical, to act as friends and advisers of the patients. I propose that there should be classes. They would be on the lowest form on entrance, and rise accordingly as they gained in self-control. I should be aided not only by the resident officers, but by those patients who had been in the longest and recovered from the effects of this baneful habit. My plan contemplates finding occupation for every patient; not mere occupation that will afford them no amusement, or that when done will be without result. They would not be set to useless tasks simply to keep them employed, such as sailors have to do in holystoning the decks, but they will feel that what they are doing will be of service to themselves and others. I need not say that all this will, from the moment they enter such an asylum, strengthen their habits of self-control. These poor creatures have in many cases lost all power of self-control and self-respect; but when you put a patient under the conditions just now mentioned, he is for that moment under some kind of mental exercise, he is practising some kind of self-control for himself, and we all know what the power of habit is. We know that the longer he remains, the more he is able to restrain these feelings, and the stronger will their growth be. Hence the

temptation to go astray will be less, and the temptation to do good will be more.

Sir GEORGE BURROWS, M.D., President of the Royal College of Physicians, moved the first resolution: "That this meeting, looking to the great and increasing prevalence of intemperance and the misery resulting both to the individual and to the community at large, is of opinion that the institution proposed to be established by Mr. C. Holthouse, is both desirable and much needed. This meeting, therefore, pledges itself to promote the success of the undertaking". He said he was glad to appear on the present occasion to support his friend Mr. Holthouse in his philanthropic movement to help those who were incapable of helping themselves. Many of these unfortunates were by no means lost to shame, nor had all self-control left them. They deeply deplored their state, and desired to reform. Certainly they were not fit for the companionship of lunatics, and he was certain Parliament would never sanction any scheme that would place them on that level. He thought the institution proposed would be a great public blessing.

Dr. WOOD, Physician to St. Luke's Hospital, seconded the resolution, and said that he had more opportunities than most men of watching the dire effects of intemperance. It was perfectly true, that a dipsomaniac was not a fit subject for a lunatic asylum, but he very soon would be if not assisted in the great struggle of his life, viz., self-control.

Archbishop MANNING said he was glad that this movement had emanated from medical men, for no class had in their hands so powerful a control of this subject as they had. He cordially approved of the proposed home.—The resolution was carried unanimously.

The Rev. DONALD FRASER, D.D., moved a resolution to raise £6,000, partly by the issue of shares of £25 each at five per cent., secured on the property, and partly by the generous help of voluntary contributors. He believed that dipsomania was a disease which was perfectly curable if taken in time and subjected to proper medical treatment.

Mr. ERNEST HART seconded the resolution, and said that the safeguard of an institution such as this, is, and always should be, that it was in some respects under the public eye and public management. The resolution was carried.

Dr. DRYSDALE moved a resolution for the appointment of three trustees mentioned in Mr. Holthouse's speech.

Mr. ROBERT RAE, in seconding the resolution, said he had had some experience of the necessity of such institutions as had been attempted to be formed that day. He was glad these steps had been taken, and trusted that Mr. Holthouse would succeed in thoroughly establishing a large institution for the treatment of dipsomania.

The motion was carried, as was likewise a vote of thanks to the Chairman.

REPORT ON THE OUT-PATIENTS OF THE ROYAL FREE HOSPITAL.

WE have received a Report upon the social position of the out-patients at the Royal Free Hospital, which has just been published by the Charity Organisation Society; and, as it has an important bearing upon the question of hospital abuse, the following extracts will be read with interest.

"In July 1874, the Managing Committee of the Royal Free Hospital entered into communication with the Council of the Charity Organisation Society with a view to obtaining a thorough inquiry into the social position of their out-patients. In the following October, the Council took the necessary steps for complying with this request. A member of the Council kindly undertook to superintend the investigation; the Committee of the Hospital agreeing to pay two assistants for a month to take down particulars of cases under his direction, and to do other clerical work. Every pains was taken by him to ensure that the cases inquired into should represent a fair average of the patients usually attending the hospital.... Each case has been considered separately on its own merits. The general rules which have guided the investigators, in the absence of exceptional circumstances, may be thus summarised.

"1. Those are set down as able to pay a private practitioner who are earning 40s. a week or more.

"2. Those earning from 20s. to 40s. are considered proper members for provident dispensaries; also single persons in some cases, when earning less than 20s. a week.

"3. Persons earning less than 20s., but still enough for their support in health without parish assistance, are classed as 'proper applicants'.

"4. 'Parish cases' include all those who are actually in receipt of

parish relief, either for themselves or any of their family, as well as those who can barely support themselves by their earnings during health, and who in time of sickness cannot obtain even the necessities of life.

"5. The fifth class consists of those who have given false information as to name or address. It no doubt embraces many persons of immoral character, who made false statements with a view to concealment.

"6. When the information obtained was not sufficient to enable the investigators to form any opinion, the case has been set aside.

"In adjudging cases to classes 1 and 2, great allowance has been made. Those who have conducted the inquiry have no doubt that many persons whom they have placed in class 2 would be included in class 1 if the opinion of the general practitioners of the neighbourhood were taken; and they are practically the best judges of what the lower middle class can pay. With regard to class 3, in the opinion of those who conducted the investigation, the whole body of the out-patients is really divisible into two sections: *a*, those who might reasonably be expected to pay something for their medical relief; and *b*, those who ought to be referred to the parish. So much allowance, they say, has been made in respect to the cases which have been called 'proper applicants', that it may be confidently asserted that many of them could pay a trifle for themselves, while the rest would have no difficulty in obtaining a parish order.

"Judging the 641 cases that have been investigated upon these general principles, subject to the qualification referred to, it was found that they divided themselves as follows.

1. Number who could afford to pay a private practitioner	12
2. Number who could afford to subscribe to a provident dispensary	231
3. Proper applicants	169
4. Parish cases	57
5. Number who gave false addresses	103
6. Number about whom sufficient information was not obtained	69
Total	641

"From these figures, it results that, after excluding the 172 contained in the two last classes, $2\frac{1}{2}$ per cent. of the remainder were considered suitable for private practitioners, 49 per cent. for provident institutions, and 12 per cent. for parish assistance, whilst 36 per cent. are classed as proper applicants.

"Looking at these cases as a whole, it seems clearly undesirable to admit to the benefits of a charitable institution the persons who have been placed in class 1. It is more difficult to say how class 2 ought to be dealt with; and yet it forms such a large proportion of the whole number, that we can hardly be contented with the present state of things. It is precisely for this class of persons that some change is required in the mode of administering medical charity in the metropolis. The great majority of them are no doubt unable to pay even the lowest scale of a general practitioner's charges; but they are well able to contribute a small amount towards the cost of their own treatment, as many of them would gladly do. It is most desirable that this feeling of independence should be encouraged, and it has been shown in many instances that a plan can be adopted which is alike advantageous to the patients and to the medical men. As the title given to class 2 imports, this could, in our opinion, best be effected by putting them in relation with a provident system of medical relief. Whether or how this can be carried out at the Royal Free Hospital, it is not within the scope of this Report to say. It may be permissible, however, to call attention to the Royal Albert Hospital, Devonport, where the out-patient department has for some years been carried on upon the provident principle with marked success; and to the increase in the number of provident dispensaries which has taken place of late years, notwithstanding the difficulties they have had to encounter from unequal competition with free hospitals and dispensaries. If a provident branch could be established, or if a provident dispensary could be affiliated to the hospital, this would very materially facilitate the better regulation of outdoor medical relief. A large proportion of the applicants for out-patient relief might then be rejected, or rather referred, without the least appearance of harshness. Any such institution ought to be self-supporting. It should be served by the out-patient staff of the hospital, and a great part of the members' payments should go to form a fund from which the medical officers should receive an honorarium for their services."

Any one who wishes to see the Report in full should apply at the office of the Charity Organisation Society. We shall reserve our comments upon it until a future occasion.

THE ABUSE OF HOSPITALS: THE MEMORIAL TO THE COMMITTEE OF COUNCIL.

DURING the last fortnight, the following names have been added to the list of those who have already signed the memorial.

Sir Thomas Watson, Bart., Dr. Priestley, Mr. De Morgan, F.R.S., Dr. Habershon, Mr. Luther Holden, Dr. Langdon Down, Mr. Maun-der, Mr. Soelberg Wells, Dr. Southey, Dr. Duffin, Mr. Mason, Mr. Wagstaffe, Dr. Waller Lewis, Dr. Palfrey, Dr. Pye-Smith, Mrs. Garrett Anderson, Mr. James Adams, Mr. Andrew Clark, Dr. Bathurst Woodman, Dr. Winter Fisher, Dr. Sidney Coupland, Mr. Albert Kisch, Dr. Alfred Sheen (Cardiff), Dr. Thomas Stainthorpe (Hexham), Mr. Wright Baker (Derby), Dr. Henry Goode (Derby), Dr. W. G. Curgenven (Derby), Mr. F. W. Wright (Derby), Dr. Otto Wyer (Leamington), Mr. Fenn Clark, (Leamington), Dr. Robert Slack (Leamington), Dr. Thomas Birt (Leamington), Dr. Henry Harris (Redruth), Dr. Kirwan King (Welwyn), Dr. F. M. Pierce (Manchester), Mr. T. N. Dean (Manchester), Dr. Clough Spencer (Manchester), Mr. H. Stear (Saffron Walden), Dr. C. J. Workman (Teignmouth), Dr. Goodridge (Bath), Mr. W. D. Wathen (Fishguard), Mr. J. Hancocke Wathen (Fishguard), Dr. G. Lorimer (Buxton), Mr. Jabez Thomas (Swansea), Mr. Edward Crossman (Hambrook), Mr. J. W. Plaxton (Hull), Dr. Deville (Harrogate), Mr. Arnold Thomson (Southall).

The memorial itself we printed on January 2nd. More than 250 signatures have already been affixed to it. Gentlemen who are desirous of adding their names, are requested to communicate with Dr. Meadows, 27, George Street, Hanover Square, or with Mr. Fairlie Clarke, 12, Mansfield Street, Cavendish Square, W.

MEDICO-LEGAL REPORTS.

MANSLAUGHTER BY INFECTION: COMMITTAL OF A MIDWIFE.

WE have again to record the criminal prosecution of a midwife for the propagation of puerperal fever.

At the Salford Borough Police Court, on Saturday, before Sir J. I. Mantell and Mr. W. W. Goulden, Elizabeth Marsden, a midwife, living in Chapel Street, Pendleton, was brought up on remand, charged with causing the deaths of Mary Ellen Goodier, of Union Street, Pendleton, and Ann Mills, of Woden Street, Salford. Mr. Smyly appeared for the prisoner. The investigation of the case was commenced on the preceding Tuesday, when prisoner was charged with causing the deaths of three married women; but, as regarded two, the charge was dismissed. The evidence went to show that prisoner, while suffering from puerperal fever, had attended a number of midwifery cases in the districts of Pendleton and Regent Road; and it was assumed by the prosecution that four of the women whom prisoner had attended in their confinement had died from puerperal fever, communicated to them by her.

Ellen Goodier, wife of John Goodier, said that her daughter, Mary Ellen Goodier, was confined on February 8th of a daughter, and prisoner attended her in her confinement. On the 11th, she became very ill, and witness, on prisoner's advice, called in Mr. White, surgeon, of Broad Street, Pendleton. Prisoner afterwards visited her daughter three times after Mr. White was called in.

Mr. J. A. White, surgeon, said he was called to attend Mary Ellen Goodier on February 11th. She was suffering from puerperal fever, and died on the 16th. On the latter date, he called upon prisoner, and advised her to destroy her clothes and rusticate for a month. She said that she had attended Mary Ellen Goodier.

Mr. Smyly submitted that there was nothing to show anything like criminal negligence. All that Mrs. Marsden was responsible for was, that she should show in her business an amount of skill commensurate with that which she professed. Where a woman did not hold a certificate, she could not be expected to possess anything more than a mere routine knowledge of her business.

Sir J. I. Mantell: Nothing is more generally known than the extremely contagious character of puerperal fever. The strongest ground against the prisoner is the warning she received not to attend any more cases.

The prisoner was committed for trial at the assizes on the first charge. The charge of causing the death of Ann Mills was then proceeded with.

Elizabeth Nicholls, wife of William Nicholls, Salford, said that, on February 15th, she went for prisoner to attend Mrs. Ann Mills in her confinement. Prisoner attended Mrs. Mills, who gave birth to a daughter the same day. On the 16th, prisoner came to witness and told her to go for a doctor. She went for Mr. Knowles, and he visited Mrs. Mills the same day. The prisoner came to Mrs. Mills three times.

Mr. H. Knowles, surgeon, said he was called to see Ann Mills on the morning of February 16th. He found her suffering from symptoms which indicated inflammatory disease in the bowels. She died on the morning of February 18th. He refused to give a certificate of the cause of her death until he had made a *post mortem* examination, because an accusation had been made that she had received violence. He made a *post mortem* examination, but found no indication to warrant the accusation; there was diffused inflammation of the lining membrane of the bowels, but no indication of injury. He had no hesitation in saying that Mrs. Mills died of puerperal fever. In cross-examination, he said that he would not have said that she died from puerperal fever, unless he had heard the evidence, which, he thought, established contagion. The case of Mrs. Mills was of a mixed character; there were other things in connection with it.

Sir John Mantell: Would you say that she died of puerperal fever?—Witness; Yes; undoubtedly, the contagion was the cause of the inflammation of the bowels.

Cross-examination continued: He certified that the cause of death was inflammation of lungs and bowels in connection with parturition. The certificate was given after the *post mortem* examination, and bearing in mind the symptoms he had seen while attending the patient.

Sir John Mantell: It appears to me that all the incidents connected with puerperal fever existed, though they may have existed spontaneously without contagion; but now, knowing what he does, the doctor has no hesitation in saying that it was a case of puerperal fever. To my mind, there is an overwhelming suspicion that it was a case of puerperal fever.

The prisoner was then committed for trial at the assizes, and an application for bail was refused.

SPECIAL CORRESPONDENCE.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

The late Mr. W. Smith.—Students' Debating Society.—Microscopical Section of Medical Society.—Bazaar in Aid of the Children's Hospital.—New Convalescent Hospital.—Hospital Saturday and Sunday.

MR. W. SMITH'S death was very sudden, but not quite unexpected, as his health for a short time past had been a source of some anxiety to his family and friends. Whilst examining a patient at his consulting-rooms, he fell back in his chair, and expired in a few minutes. The funeral was attended by a large assemblage of persons; nearly all his colleagues were present; the Infirmary board was represented by some of its most influential members, and Owens College by Professor Greenwood. There was besides a very large attendance of students and former pupils. Mr. Smith's genial manner and kindness of heart had endeared him greatly to colleagues, pupils, and friends; his loss will be most severely felt, and his place not easily filled. His reception at the opening of the new Medical School, last October, is fresh in the memory of all who were present, and will not be readily forgotten. There will be no vacancy at the Infirmary, as the surgical staff is to be henceforth limited to four surgeons and two assistant-surgeons.

In connection with the Medical School, a Students' Debating Society has been organised. The meetings are held fortnightly; a paper is read, and a discussion afterwards takes place. We have been present at some of the meetings, and have been much delighted with the practical nature of the papers read, and of the speeches that have followed.

The first meeting of a Microscopical Section of the Medical Society was held on February 23rd, when several very interesting specimens illustrative of the various sarcomatous tumours were exhibited. The meetings of the Section are to be held on the third Tuesday in each month, except the months of August and September, and its members are those of the parent society who subscribe the annual sum of five shillings.

In the second week of next month, a Bazaar is to be held in the Free Trade Hall, in aid of the Children's Hospital. At present, the institution contains eighty-four beds, but when finished it is intended that it should have double that number. On the present building there is a debt, which the promoters of the bazaar intend to wipe off, and with the surplus money to afford the board an opportunity of completing their plans by building three more wings, each containing twenty-six beds. The chief features of this Bazaar are the immensity of the scale on which it is to be held, and the great and increasing interest taken in it by ladies in the surrounding districts, as shown by stalls to be presided over by ladies of Bowden and Alderley.

The new Convalescent Hospital belonging to the Infirmary, and due to the munificence of the late Mr. Barnes, is fast approaching completion. When finished, there will be accommodation for one hundred and twenty patients; it is fully expected that a portion of the building will be occupied in three months.

February 20th and 21st were Hospital Saturday and Sunday, and the annual collections in aid of the local charities of Manchester and Salford took place. Formerly, there had been a week's interval between the two Hospital days. This year it was determined to hold them on consecutive days, in the hope that better results would be obtained.

ASSOCIATION INTELLIGENCE.

WEST SOMERSET BRANCH.

THE spring meeting of this Branch will be held at the Royal Clarence Hotel, Bridgwater, on Thursday, March 18th, at 5.15 P.M. The following question has been settled by the Council as the one on which each member should be asked to express his opinion at the said meeting: "What in your opinion is the best mode of treating habitual drunkards?"

Communication Promised.—Dr. Alford: On the Causation of Typhoid Fever. W. M. KELLY, M.D., *Honorary Secretary*.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE next meeting will be held at the Harp Hotel, Dover, on Thursday, March 18th, 1875, at three o'clock; FRANCIS E. BARTON, Esq., in the Chair. Dinner at five o'clock precisely; charge, 5s., exclusive of wine.

The Chairman kindly invites members and their friends to luncheon at his residence, 6, Cambridge Terrace, at half-past one.

Notices have been received of the following communications to be read at the meeting.

1. Mr. Osborn: Case of Intussusception of the Rectum.
2. Dr. Joyce: Diphtheria, with illustrative cases.
3. Mr. Robinson: Short Notes on Epidemics of Diphtheria and so-called Croup in East Kent during 1874.
4. Mr. Marshall: Paracentesis Abdominis; the advantage to be derived from using a small Trocar and Cannula.
5. Mr. Clement Walter: A Few Remarks on Diabetes.

Gentlemen who intend to be present at the dinner are particularly requested to inform me on or before Tuesday, the 16th instant.

EDWARD WHITFIELD THURSTON, *Honorary Secretary*.
Ashford, March 9th, 1875.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.

THE first meeting of the above district for the present year will be held on Wednesday, March 24th, at Tunbridge Wells, at 3 o'clock P.M.; BLACKALL MARSACK, Esq., in the Chair.

Dinner will be provided at 5 P.M., at the usual charge.

All members of the South-Eastern Branch are entitled to attend these meetings, and to introduce professional friends.

Notice of intended communications is requested by Tuesday, the 16th instant, in order that they may be duly inserted in the circular convening the meeting.

THOS. TROLLOPE, M.D., *Hon. Sec.*
35, Marina, St. Leonard's-on-Sea, March 9th, 1875.

SOUTH OF IRELAND BRANCH: ORDINARY MEETINGS.

AN ordinary meeting of this Branch was held in the Theatre of the Royal Cork Institution on February 10th, Dr. THOMAS GREGG, President, in the Chair.

Hydrate of Chloral in Puerperal Convulsions.—Dr. O'FLYNN brought forward a case of puerperal convulsions of an epileptiform nature, in which hydrate of chloral had been used with the best effect. It was given in the intervals between the paroxysms, in fifteen-grain doses, at first every second, subsequently every third, hour. The convulsions ceased within twenty-four hours after the termination of the labour. An interesting discussion followed, in which Drs. Cummins, Jones, Atkins, and the President, took part.

Menière's Disease.—Dr. JONES brought forward the notes of two cases of Menière's disease. CASE 1. Mary J., aged 40, dressmaker, had had deafness over two months. It came on after cold caught while sitting up at night nurse-tending. There was constant tinnitus

with the right ear, a watch was heard on contact; a tuning fork, she thought, the same at both sides, and less loudly on closure. With the left ear, a watch was not heard on contact. The membrana tympani of each ear was rather dull and concave; and the malleus was unduly prominent. She was subject to occasional attacks of vomiting and fits of giddiness, with louder noises, and "a tendency to fall forwards, which she would do if she did not support herself". CASE II. M. H., a servant, aged 60, had had deafness over one year. There was a constant noise "like a great storm". She referred this to the back of the head; and said she had lately become "afraid to walk", that she "felt as if she were falling down". Her conversational powers were good; but the watch was barely heard on contact with both ears. She thought a tuning-fork was heard better with the right ear, but badly in both. She was confident that closure made her hear worse. The affection came on, she said, after a gastric attack, and at first she suffered from severe megrim. In both ears, the membrane was dull, concave, and irregular. In neither of the cases was there any accompanying lesion of the retina. One case appeared to improve on the administration of bromide and iodide of potassium, alternately with strychnine, vesication, inflation, and the daily injection of iodide of potassium with the Eustachian catheter; but any cases of this affection which Dr. Jones had seen were obstinate and intractable.

Rhinolith.—Dr. CUMMINS brought forward an interesting case of a small calculus which he had removed from a lady's nose. Dr. R. Atkins had examined a section under the microscope, made by grinding down the specimen, and found it to be composed of a "granular matrix", surrounded by a horny covering. The case was more particularly interesting from the extreme rarity of such depositions in the nose.

An ordinary meeting was held in the Theatre of the Royal Cork Institute on February 24th, Dr. GREGG, President, in the Chair.

Bad Compound Fracture of the Bones of the Leg: Recovery.—The PRESIDENT detailed the particulars of a most severe injury received in the hunting-field, the gentleman fracturing both bones a few inches above the malleoli, and tearing the tendon of the tibialis posterior, which protruded from the wound, which was extensive, the integument being torn both anteriorly and posteriorly. Besides small portions of bone that exfoliated, a large portion of the half detached fragment of the tibia had to be removed. The case, the President said, he brought forward as an instance of the extent to which conservative surgery could go, in saving a limb even under such extremely unfavourable circumstances as presented themselves in this case. Holmes's splint and carbolic dressings were used throughout.

Dislocation of Humerus reduced after Five Months.—The PRESIDENT related the case of a woman, aged 33, admitted into the County Hospital on January 28th, the injury having occurred on September 5th previously, from an accident which was caused by a threshing-machine, in which her arm was caught. The nature of the injury was overlooked. On presenting herself at the hospital, the usual appearances of dislocation under the clavicle, the head of the bone being fixed in this position, and adherent to the neck of the scapula. On February 3rd, the reduction was effected under chloroform, with pulleys. The usual apparatus employed in the hospital for old standing luxations of the shoulder-joint, is a gutta-percha shield, which fits from spine to sternum, with an aperture for the arm, carefully moulded and bandaged to the body. This protecting shield affords a means of steadying the scapula, and also a fixing point for the straps, and preventing injury to the ribs. The President cited several instances of old standing luxation, which, he said, could not have been reduced but for the use of this gutta-percha shield.

Removal of Tumour of Superior Maxilla.—The PRESIDENT detailed the particulars of a case of removal of a tumour from the superior maxilla. The tumour grew from the anterior and was completely dissected out, and any diseased portion of bone removed. On microscopical examination, however, by Dr. Atkins, characteristic, free, and aggregated cancer-cells were seen, with loculi, making up nearly the entire structure of the sections examined, specimens of which were exhibited to the members. This made the return of the growth a matter of certainty.

Removal of Superior Maxilla.—Dr. JONES exhibited a photograph, taken before and after operation, of a woman from whom he had removed the entire superior maxilla, but in which, as he feared before hand, the disease recurred in the soft parts, the skin being slightly involved. He performed the operation after full consultation at the urgent solicitation of the patient.

SOUTHERN BRANCH: SOUTH HANTS DISTRICT.

A MEETING of the above District was held at Portsmouth, on Tuesday,

February 23rd. Fifteen members were present, and Mr. W. H. GARRINGTON occupied the Chair.

1. Dr. ANFORD read a paper on Dysmenorrhœa. He referred especially to the membranous form of the disease, and exhibited some excellent specimens of fibrinous exudations from the uterus.

2. Dr. WARD COUSINS read some notes in a successful case of Excision of the Knee-Joint. The patient was examined by the members. He also brought forward a patient of twelve years of age, who had made a good recovery after suffering for some years from extensive central necrosis of the shaft of the humerus. The sequestrum had separated very slowly, and several operations were necessary to remove it completely.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 9TH, 1875.

Sir JAMES PAGET, Bart., F.R.S., D.C.L., LL.D., in the Chair.

URINARY CRYSTALS AND CALCULI: BEING OBSERVATIONS ON SOME OF THE CIRCUMSTANCES DETERMINING THE FORMS OF CRYSTALLINE DEPOSITS IN URINE, AND ON SOME OF THE CONDITIONS UNDER WHICH RENAL AND VESICAL CALCULI ARE PRODUCED.

BY WILLIAM M. ORD, M.B.LOND., M.R.C.P.

1. THE starting point of the paper was the remarkable difference between the crystalline form of pure uric acid and the form of uric acid in urine: the former being in oblong rectangular tablets, the latter in rhombohedra with rounded obtuse angles; the former in separate crystals, the latter very often in zeolitic masses. After a brief notice of former observations showing that uric acid deposited in the presence of albumen and other colloids tended to assume spherical form, and in the presence of sugar and other crystalloids, tabular and angular form, a series of experiments having for their object the determination of the causes of the altered form of urinary uric acid were related. The conclusions drawn from these experiments were that mucus and the colouring matter of the urine were both agents in producing the ordinary urinary form of uric acid; that either agent was capable of exerting this influence without the presence of the other; that these were probably the sole agents in ordinary urine.—2. The forms of uric acid in albuminous urine were next considered. It was remarked that, while they tended generally to sphericity, they varied much in the degree of their tendency. It was inferred from a series of observations which are related in a generalised form that a larger proportionate quantity of urea in albuminous urine constituted *pro rata* an obstacle to the sphere-forming process.—3. Two forms of uric acid were noted as occurring in sugary urine: one a flat rhombohedron, with chiselled ends; the other a six-sided tablet, with sharp ends, the latter being a rare form.—4. Purulent mucus was shown to have a great power of converting uric acid to sphericity, and of causing aggregation of spheres into calculi. Dr. Vandyke Carter's observations on the structure of calculi were referred to, and it was argued that the experiments now related agreed from the synthetic point of view with his analyses. The influence of colloids, and particularly of mucus, in favouring the formation of calculi within the urinary passages, was inferred to be of first importance, and much worthy of regard as bearing upon practice. Uric acid and other crystalline substances did not of themselves tend to form calculi, but were moulded by the other constituents of the urine. The part taken by the temperature of the body in furthering the process was discussed and regarded as important.—5. The forms of urates, and the influence upon them of chlorides, albumen, and mucus, were next noticed; mucus in a high degree, and albumen in a less degree, were noticed as favouring the formation of spheres, chiefly in association with a concentrated condition of the urine. This particularly applied to the spherical form of urate of soda observed by Golding, Bird, Thudichum, Beale, Roberts, and others.—6. As to oxalate of lime, the formation of dumb-bells under the influence of colloids, already elsewhere suggested by Dr. Beale, and described by the author, was referred to, and several cases of spheroidal modifications of oxalate of lime in urine containing colloids were brought forward.—7. Triple phosphate was much less easily moulded by colloids than the substance hitherto treated. But it was shown that mucus, aided by warm temperature, could and did modify triple phosphate towards sphericity, and favour calculous deposit. And the forms obtained under such circumstances agreed in a remarkable way with the forms of triple phosphate found by Dr. Vandyke Carter in calculi.—8. The influence of albumen on the form of nitrate of urea was noted.—9. With regard to the bearing of the foregoing observations on micromorphology, it was urged that, in the microscopy of the

future, beyond recording the forms of the tissues, observers would interpret the meanings of forms, compelling form to tell the story of growth and function, following out the relations between form and substance, and proceeding to the discovery of the laws of tissue-formation.

Mr. C. BROOKE, referring to one of the figures of oxalate of lime exhibited, asked whether the pentagonal appearance was correct. It seemed to him not reconcilable with any known form of molecular aggregation.—Dr. ORD said that the drawing was rather difficult to make correctly, as both the centre and the circumference had to be represented. As far as he could make out, the form was a transitional one between an octahedron and a sphere.—Dr. DICKINSON remarked that Dr. Ord had referred to uric acid as the most common centre of calculi; and this statement was very commonly made. He thought, however, that it was not founded on fact. He had examined numerous calculi in the London museums, and had found that in the majority of them the real centre was oxalate of lime, though it might be in small quantity. Calculi were most frequent in limestone districts, and where the water was hard. Their formation most probably depended on the excretion of lime in the urine, rather than on any condition of the urinary passages, such as vesical catarrh.—Mr. THOMAS TAYLOR said that the alteration of form of crystals described by Dr. Ord was an illustration of the general law of crystallisation, that crystals were deprived of their angles by contact with foreign matters. He believed that Dr. Ord had referred to what had been called by some the blastema of calculi; mucus was a very indefinite term. The mucus of the bladder seemed scarcely to be the basis for the formation of calculi. At the Royal College of Surgeons, he had examined numerous calculi, but had great difficulty in dissolving out the earthy matter without destroying the animal matter. On placing under the microscope, however, portions of the concretions found in the surgeon (*Alepeser fuso*), and treating them with nitric acid, the earthy matter was dissolved out, leaving the animal matter in the original arrangement. He could not, however, determine what this animal matter was. It appeared to him that the formation of calculi took place in some such way as the following. Long before any irritation was set up in the bladder—and it must be remembered that calculi might exist for years without producing inconvenience—the uric acid was secreted, perhaps at first in a hydrated form, after which it shrank and formed minute crystals, which became coated with animal matter, perhaps of the nature of coagulable lymph, or perhaps like the exudation under the scales in some skin-diseases. Calculi were generally preceded by discharge of gravel; but a person might pass gravel for years, and yet have no calculus. He had thought it possible that in certain cases irritation took place in the kidney, where a species of inflammation was set up, leading to the secretion of fluid, and thus to the formation of calculi. He advanced this opinion, however, with some hesitation. But he believed that the formation of calculi would have to be explained by the anatomist rather than by the chemist. He recommended that, in cases of persons dying with calculus, the kidneys should be congested and examined with a view to ascertain whether there was any pathological change. (This, of course, did not refer to the secondary changes induced in the organ.)—Mr. SAVORY said that the paper was interesting as pointing to the influences exerted on form. In both, the earthy matter was deposited in granules. In some parts of shells, there was an approximation to angular forms: in the interior of cystic shells, distinct crystals were formed. Mr. RAINEY had found that crystals with rounded edges were precipitated from a solution of common salt with gum.—Dr. BROADBENT remarked that Dr. Ord had given a special direction to the observations made by Mr. RAINEY. Dr. Beale had found that the nuclei of calculi, apparently uric acid, consisted of oxalate of lime.—Dr. ORD, in reply to Dr. Dickinson, stated that he had not said that the nuclei of most calculi consisted of uric acid, but that the bulk of most calculi consisted of this. (Dr. Dickinson expressed assent.) But, whatever might be the nucleus, we still had to get at an explanation of the formation of calculi. He admitted that mucus was a bad term; but it did not follow that, because the animal matter left after removal of the earthy matter of calculi had not the reaction of mucus, it was not originally mucus. He had been a pupil of Mr. RAINEY, and thought that his observations had remained in an obscurity which they did not deserve.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

TUESDAY, FEBRUARY 11TH, 1875.

W. T. GAIRDNER, M.D., President, in the Chair.

Pityriasis Rubra Acuta recurring during Seventeen Years: Febrile Movement: Influence of this on Nails.—Dr. GAIRDNER introduced a patient, who had recently recovered from an attack of pityriasis rubra acuta (Devergie), for which he had been under treatment both in the

Royal Infirmary and in the Western Infirmary. The case was one of a certain historical interest in Glasgow, inasmuch as its commencement had been described in an article by the late Dr. McGhie in the *Glasgow Medical Journal* for 1858 (vol. v, p. 431): and, during nearly seventeen years past, the patient has been repeatedly under observation in numerous invasions of the disease, separated by intervals of years, during which he states himself to have enjoyed tolerably good health. Each invasion lasts, as a rule, for months, and consists of a number of successive desquamations of the cuticle, over the entire surface of the body. The invasions have been, on the whole, diminishing in severity; and, notwithstanding the gloomy prognosis held out by Devergie and others in this disease, there seems a fair presumption that he may survive it, as his organs are even now perfectly sound; and, although emaciated, he is by no means in very greatly impaired health. The object of presenting this man to the Society, however, was not to describe the disease at large, but to give evidence of one feature of it which is overlooked, and even denied, by some authorities—viz., the distinctly febrile character of the invasion, especially in its early stages; and the effect of this upon the growth of the nails. In this man, the nails have always been (when under observation of late years) much curved, though without much, if indeed any, clubbing of the finger ends. In the last invasion of pityriasis, which began in the first days of October 1874, the temperatures were carefully noted for nearly two months, every morning and evening, from October 3rd onwards. The maximum temperature noted was 103.8 deg. Fahr. on October 5th; but, for some days after the commencement of the invasion, the temperatures were oftener above than below 100 deg. Fahr., and it was not until October 5th that normal temperatures were recorded. After this, although the fever was slight, it was still occasionally apparent, as on October 17th, when 101.2 deg. morning and 100 deg. evening were noted; and on October 26th and 28th, when a new maximum of 102.6 deg. Fahr. was attained, with adjoining observations of 101.8 deg. and 100 deg. In general, the morning temperatures were normal, or even subnormal on the majority of days, except at the periods above referred to; but the evening temperatures often presented a rise, which, though not altogether beyond the possible limits of health, were distinct in comparison with the morning range in this man. In the end of November, temperatures of 101.4 deg., 100.8 deg., 100.6 deg. were again noted in connection with a renewed attack of desquamation. The effect of all this constitutional derangement was seen in the nails, which were not only, as stated, much curved, but presented a very evident and deep transverse furrowing, corresponding in date with the first febrile period, the portion of the nail which emerged at that time being comparatively soft and thin, and being succeeded by a more natural portion, and this again at an interval by another furrow. It was rather remarkable that in all the numerous and complete desquamations that had attended this disease during sixteen years, the nails had only once separated, viz., during the first, which was also the most severe attack; at this time, also, the hair came away a good deal, but in the latter attacks scarcely at all, and now, although dry and scurfy and a little grey, it was abundant all over the head.

Cancer of Lesser Curvature of Stomach.—Dr. WOOD SMITH showed a specimen of epithelial cancer. The tumour occupied portions of the lesser curvature and of the anterior and posterior walls. It ended abruptly at the pylorus; it measured three and a half inches along the lesser curvature, and four inches in a direction at right angles to this; it was much ulcerated, and its margins prominent and warty looking. It had adhesions to the transverse colon, and a tortuous communication existed between the ulcerated tumour and the colon. The tumour also had adhesions to the liver; the liver was smaller than usual, and had a few small white growths in its substance; some enlarged glands were also found in the neighbourhood. Dr. Wood Smith said the case had presented much difficulty in diagnosis during life: the tumour could not be distinguished from an enlarged liver: the man was sixty-three years old, and had been intemperate: there was neither vomiting nor any alteration in the character of the stools; his chief complaint was of loss of appetite and shooting pains in the right hypochondrium.

Cancer of the Bladder and Kidneys.—Dr. WOOD SMITH also showed the bladder of a man, aged 62, who suffered from hæmaturia, frequent micturition, and pains over the kidneys. The urine was of a smoky tint from blood, but no tube-casts could be found. Pneumonia on the right side appeared, and after death cancerous nodules were found in the bladder and kidneys, and under the pleura costalis.

Scurrhus of Breast.—Dr. G. H. B. MACLEOD presented a fresh specimen just removed from the breast of a healthy looking woman, aged 46. It had grown slowly, having been observed two years ago. It was only very slightly imbedded in the gland, but stood quite out like a great nipple. There were no glands affected, and no puckering of the skin or retraction of the nipple. Dr. Macleod intended merely to ex-

cise the growth and the base from which it grew, if, on section, it was found non-malignant; but, on cutting it, he saw at once that it was necessary to remove the whole breast.—Dr. JOSEPH COATS had examined sections, and found the typical structure of scirrhus.—From its unusual situation, it was referred to a committee for report.

Tumour (Malignant?) on Outer Side of Knee.—Dr. G. H. B. MACLEOD also presented a tumour removed from a woman, aged 56. It grew on the outer side of the knee-joint; and, as it seemed malignant, it was removed with all skin, etc. The joint was not implicated. It had been growing since July, and occasionally there was much pain.—Dr. JOSEPH COATS regarded the tumour as a spindle-celled sarcoma, or recurrent fibroid.—It was referred with the previous tumour to a committee for report.

Spontaneous Extrusion of the Upper Articular Epiphysis of the Femur.—Dr. MACLEOD also presented this specimen from a girl, aged 14. He had since broken up some fibrous adhesions, and the limb was likely to do well.

Atelectasis and Emphysema.—Dr. ALEXANDER ROBERTSON contributed a fresh specimen, viz., the lungs of an infant, who, for a week after birth, seemed healthy, when bronchitis set in, and extensive atelectasis was diagnosed. A large portion of both lungs was found collapsed, and patches of emphysema existed at the margins.

Large Emphysematous Bulla.—Dr. KNOX presented a preparation from the dissecting-room; the history was absent. A large vesicle about the size of a small orange occupied the dome of the pleura at the apex; it was attached to the lung by a very small flattened pedicle; traces of calcareous degeneration were noticed on the wall of the vesicle. Both lungs were slightly emphysematous throughout, but this was the only large vesicle found. The lung was injected with spirit from the bronchus to preserve it, but none entered the vesicle.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, FEBRUARY 13TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, and subsequently SIR DOMINIC J. CORRIGAN, Bart., M.D., in the Chair.

Intestinal Strangulation in a Child.—Dr. BANKS showed part of the intestines of a child aged one year, who was admitted to hospital in collapse, having passed eight days without a motion from the bowels. A large portion of the small intestine was running into gangrene, having originally been caught in a "slit" in the omentum and strangulated.

Dilatation and Hypertrophy of Heart: Sudden Death: Clot in Right Auricle.—Dr. FINNY showed the heart of a woman aged 55, who had suffered from cardiac dropsy. There was no ascites. The heart's action was excited and quick (between 90 and 100 per minute); her face was semi-cyanotic. The area of precordial dullness was increased, the cardiac impulse being undulatory and variable in character. No bruit was audible. After death, the lungs proved to be emphysematous, the right one more particularly so. As regards the heart, the right ventricle was dilated, but free from clots. A large fibrinous clot passed from the superior vena cava into the dilated right auricle, and was attached firmly to the auricular appendix. Some fluid venous blood lay free in the cavity of the auricle. The left ventricle was greatly dilated and hypertrophied. All the valves were healthy.

Pathological Changes induced by Urthral Stricture.—Dr. McDONNELL laid before the Society the urinary organs of a man aged only 32, who had long suffered from a close stricture, which was easily cured by operative measures. The patient constantly passed mucopurulent urine. At the necropsy, the bladder was found to be small, its surface rough, and entirely coated with lymph; the ureters were enormously enlarged, their walls being much thickened. The kidneys were of immense size; the pelvis and calices dilated and filled with mucopurulent urine. The cortical substance had almost disappeared from the right kidney, while the left was rather more healthy. No right testis, or even a vas deferens, on that side could be detected.

Abscess of Cerebellum, due to Disease of Temporal Bone.—Dr. T. EVILAN LITTLE presented a specimen from the body of a woman aged 30, who for ten or twelve years had been the subject of otorrhoea. For three weeks previously to her admission to hospital, a group of symptoms pointing to intracranial mischief had been present. These were pain in the ear, and headache, slight photophobia, lethargy, persistent vomiting, and sleeplessness. There was only very slight deafness, and no facial palsy existed. Just before death, her pupils became widely dilated. An adhesion was found between the right hemisphere of the cerebellum and the petrous portion of the corresponding temporal bone. In the cerebellum lay an abscess, equal to a walnut in size. A second abscess separated the dura mater from the bone, which it penetrated behind the internal auditory meatus; hence the

absence of any paralysis of the seventh nerve. The lateral sinus was healthy, but the petrosal sinus was plugged. Effusion into the lateral ventricles had been the immediate cause of death.

Disease of Temporal Bone: Secondary Inflammation of Orbit.—Dr. BARTON showed the left temporal bone of a boy, 13 years old, the subject of chronic otorrhoea. When admitted to Hospital, he was partially paralysed, his pulse was 116, and he suffered from constant sleeplessness. The pupils were dilated, and acted sluggishly on stimulation by light. The right eyeball ultimately became protruded, and the conjunctiva was inflamed. After death, evidences of general arachnitis were discovered, lymph being plentifully effused at the base of the brain, in the Sylvian fissures, etc. No abscess or pus was found. The right eyeball was bathed in a depot of pus. The petrous portion of the temporal bone was not carious; but destructive inflammation had occurred in the middle ear, and a perforation leading from the mastoid cells to the upper part of the lateral sinus had caused the engagement of the orbit.

SATURDAY, FEBRUARY 20TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

Aneurism of the Thoracic Aorta.—Dr. C. J. NIXON showed a specimen from the body of an intemperate man, who had complained for two months only, and who had been admitted to hospital with symptoms resembling those of the last stage of phthisis. There was marked pulsation of the carotids, with *frémissement*. Over the base of the heart a *bruit de séie* was audible, and an area of dullness on percussion existed under the sternum and left clavicle. There was no aphonia, but stridulous breathing and a hoarse cough pointed to some implication of the recurrent laryngeal nerve. The diagnosis was, incompetency of the aortic valves and aneurism of the transverse aorta. After death, the aorta was found dilated above the valves, which were diseased. An enormous aneurismal sac sprang from the terminal portion of the transverse aorta, occupying the posterior mediastinum, eroding the vertebrae, and pressing on the recurrent laryngeal nerve. Three or four pounds of fluid blood lay in the left pleural cavity, having escaped through a small rent in the wall of the aneurism. The aorta was throughout very atheromatous. Amongst other things, the case illustrated the masking of the signs of aneurism by the presence of bronchitis (Stokes), and the suddenness of death consequent on the rupture of the sac into a serous cavity (Addison).

Dilatation of Heart.—Dr. FINNY showed the thoracic viscera and liver of a woman who suffered a year before from swelled leg and great dyspnoea. She did not complain much, however, for many months. She ultimately was admitted to hospital with purpuric spots, anasarca, and dyspnoea. The percussion note over the chest indicated *emphysema pulmonum*. The area of precordial dullness was enlarged, and the heart's impulse was irregular and diffuse. The right jugular vein was permanently varicose. After death, the pericardium was found adherent to the heart, and an encysted pericarditis was observed encircling the origin of the great vessels at the base. The walls of the right auricle were attenuated, atheromatous, and fatty. The left ventricle also was fatty, and there were old caseous deposits in the lungs. The liver was square-shaped, and showed evidences of commencing disease.

Congenital Malformation of the Clavicle.—Dr. G. H. BENNETT laid on the table three specimens of a congenital malformation of the outer end of the collar-bone, similar to that demonstrated by him at the meeting of the Society on February 8th, 1873. [See BRITISH MEDICAL JOURNAL, May 31st, 1873, page 631.] In every case the deformity existed only on the left side of the body. It consisted mainly in the acromial extremity of the clavicle being bitid, and its articulation with the scapula double.

Mode of Recurrence of Sarcoma with Small Round Cells.—The PRESIDENT laid before the Society a series of specimens from the body of a man aged 21, who became the subject of a small round-celled sarcoma of the leg. The limb was amputated, and the stump healed kindly; but after some time, the urine he passed was observed on standing to become dark-coloured, apparently from oxidation of the colouring matter of the blood by exposure to the air. Shortly, the presence of blood in large quantity became unequivocal. Intense pain commenced in the neighbourhood of the lumbar enlargement of the spinal cord, and simultaneously partial paraplegia set in. The motor power was lost, the sensory power became limited, thermic impressions were wanting, but reflex phenomena could be excited. The man died. The bladder was in an advanced state of disease, but the kidneys were healthy, although anæmic. In the loose cellular tissue between the rectum and bladder lay a large sarcomatous mass, and nodules of the same form of tumour were found in, and especially at the margin of, the lungs. The inguinal glands were scarcely, if at all, enlarged or engaged, thus showing how different this connective tissue tumour was from the carcinomatous group.

As explanatory of the intense pain, two of the lower dorsal nerves showed intensely red spots close to their ganglia, and they were found to run into a mass of sarcoma just outside the theca.

Functional Tricuspid Insufficiency.—Dr. NIXON exhibited the heart and lungs of a woman aged 46, the subject of bronchitis. When he first saw her, the subcrepitant *râle* of capillary bronchitis was heard generally through the chest. After a few days, sudden and severe pain in the heart occurred. On physical examination, it was ascertained that the area of precordial dulness had much increased, especially towards the right, since the previous day, and a murmur indicated that insufficiency of the right auriculo-ventricular opening was the cause at once of the pain, and of the increased area of dulness. She was bled from the median basilic vein, with temporary marked relief, but sank in a few hours. The heart was dilated; its left chambers were bloodless. The right ventricle and auricle were gorged with blood, and a firm clot extended into the corresponding auricular appendix. The tricuspid valve was so dilated as to admit seven fingers into its opening. In the apex of the left lung were appearances resembling slaty induration of the lung.

SATURDAY, FEBRUARY 27TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

Embolism of Middle Cerebral Artery.—Dr. JAMES LITTLE showed the brain of a man who was admitted to hospital complaining of gradual failure of sight, numbness in the right arm and leg, and a peculiar gait. He constantly experienced a sense of smelling beautiful flowers, and a strange feeling in the right pectoral muscles. Atrophy of the optic disc existed. Partial right hemiplegia and complete aphasia occurred while he was in hospital, and a suicidal tendency also developed itself. In the end, the man committed suicide by leaping from a window. The brain was diseased in the area supplied by the left middle cerebral artery. This lesion had probably originated in embolism. The substance of the brain in the area mentioned was softened and diffused, and internally the left corpus striatum was less firm than the right.

Amyloid Disease of Liver and Kidneys.—Dr. HAYDEN presented specimens from the body of a temperate man, aged 26, a pipe-maker by trade. When admitted to hospital, the patient was deeply jaundiced. He stated that up to ten months previously his health had been good. Pleuropneumonia supervened. The urine, of low specific gravity (1010) was albuminous, and stained with bile-pigment. After death, the liver proved to be of very large size, presenting a marked example of amyloid degeneration. The kidneys were also enlarged and amyloid. The right lung had passed into the third stage of pneumonia, and there were thick deposits of lymph in the interlobar fissures.

Ascaris Lumbricoides discharged from Umbilicus.—Dr. MACSWINEY exhibited an ascaris which had escaped through the umbilicus of a boy aged 7. When he first saw the boy, two inches of the entozoon already protruded from the navel. With some care and difficulty, the remainder was drawn away. The animal was nine inches long, and of the male sex. A fistulous condition of the umbilicus had existed from birth, but the discharge had no feculent odour, and contained neither blood nor bile. One of Dr. MacSwiney's colleagues (Mr. Kelly) had suggested a probable explanation of the escape of the parasite in this peculiar manner; namely, that an unclosed vitelline duct had allowed it to pass from the intestine to the umbilicus.

Rupture of Renal Abscess into Peritoneum.—Dr. E. H. BENNETT showed the urinary organs of a Swedish sailor, who, seventeen months ago, had met with a fracture of the leg, and an injury in the perineum, including, in all probability, a rupture of the urethra. A suppurating fistula became established. Attacks of retention of urine, followed by symptoms of urinary fever, occurred in January last. Numerous small calculi came away through a stricture of the urethra. External urethrotomy was ultimately performed; but, some time afterwards, intense pain, amounting to agony, set in, and was referred to the left kidney. This increased, and continued to the hour of death. The peritoneal cavity was full of purulent fluid, and patches of recent lymph glued the intestines together. The colon, spleen, and left kidney were all matted together by lymph. On the anterior surface of the same kidney, a small opening allowed pus to escape freely into the peritoneum from a large renal abscess. In the left ureter, an impacted calculus was found to have caused retention of urine in the pelvis of the kidney, and so induced rupture of the abscess. The bladder showed signs of acute cystitis.

Bony Development from Choroiditis.—Mr. H. WILSON showed two specimens. One was in the eye of a man aged 40. Sight in the organ had been lost thirty years previously. On extracting the shrunken eyeball, a large cup-shaped mass of bone, a quarter of an inch in thick-

ness, and three-quarters of an inch in transverse measurement, was found. There was no trace of the retina, but the point of entrance of the optic nerve was marked by a projecting spur of bone. Remains of the choroid were detected. A second specimen had been removed by Dr. Richard Rainsford. The etiology of this bony metamorphosis was probably as follows: ido-choroiditis, plastic exudation between the retina and choroid, detachment of the retina, organisation of the exudation, and, lastly, bony transformation of the same.

Stricture and Abscess of Urethra.—Dr. THOMSON laid on the table the urinary bladder and penis of a man who died of phthisis, but who had suffered from retention of urine due to a stricture of nineteen years' standing. One day he felt something give way when passing urine, and signs of commencing urinary infiltration appeared. Internal urethrotomy was performed with marked relief, but the man sank from his pulmonary affection. The bladder was thickened as in chronic cystitis. Two strictures of the urethra existed. On the left side of the passage, there was an opening into the cavity of an abscess as large as a small walnut. The sensation of "something giving way" was clearly coincident with a rupture into this abscess of the wall of the urethra.

Diagnosis of Simple Hypertrophy of Left Ventricle of the Heart.—Dr. HAYDEN presented the heart of a man who died of chronic Bright's disease (uræmic convulsions). It was an admirable example of simple hypertrophy of the left ventricle, in which the walls of the ventricle are thickened without any lessening of its cavity. During life, Dr. Hayden had observed a most marked doubling of the first sound of the heart; and this he considered, from observations in a series of cases, to be a pathognomonic sign of the condition of parts in question.

SATURDAY, MARCH 6TH, 1875.

Tertiary Lesions of Syphilis.—Dr. W. THOMSON showed various parts from the body of a man with an eighteen years' history of syphilis. Seven years after the development of a syphilitic eruption, the patient was attacked by severe pains in the legs, and ulcers formed on the anterior aspect of the tibiae. Four and a half years ago, an ulcer of the os frontis formed. This spread until the bone was destroyed to the extent of four inches in transverse measurement. Both tables of the bone were destroyed, and there was great thickening. Epileptiform convulsions occurred the day before his death. The necropsy revealed extensive meningitis. A small induration in the white substance of the anterior lobe of the right cerebral hemisphere was examined microscopically. Its centre consisted chiefly of *alibris*, and was surrounded by a zone of thickened neuroglia. It was apparently an old abscess. Both tibiae were much diseased. The pleura was adherent. Bony ribs ran across the upper part of the right lung under the pleura, and trabeculae, as hard almost as bone, ran into the substance of the left lung. This lung, in fact, presented the pathological features of chronic interstitial pneumonia with great pigmentation. In the upper part of the tunica albuginea of the right testicle lay a mass of calcareous matter. The left testicle was atrophied. The patient had long since lost all sexual desire.

Mycosis Intestinalis (Malignant Pustule).—Dr. GERALD F. YEO exhibited the intestines of a man, who died, after seven days' illness, of malignant pustule. On the third day of his illness, he had an unhealthy pustule on the left cheek. There was considerable œdema of the integument, which was of a saffron tint. The pulse was 80. Next day, suppuration commenced in the centre of the œdematous area, dyspnoea and more or less delirium set in; pulse 90; temperature, 101.5 deg. On the fifth day, copious vomiting occurred; the ejecta resembling, according to the nurse's account, "beaten-up rotten eggs". On the sixth day, pain was complained of about the umbilicus. After death, a quantity of sero-sanguineous fluid and large clots, like blood-clots, were found in the peritoneal cavity. The peritoneum itself seemed to be healthy. The mesentery was thickened and œdematous. It was filled with large dense clots similar to those lying free in the peritoneum. There was an hour-glass constriction of the stomach, and prominent black nodules were studded over the mucous surface, as also in the duodenum. The jejunum was much dilated: the valvulae conniventes were œdematous. The large intestine was contracted. The thoracic viscera were healthy, except for some old pleuritic adhesions. The spleen was slightly enlarged: the kidneys were somewhat hyperæmic, but otherwise healthy. The fluid discharged from the stomach proved, on microscopical examination, to consist principally of very recently removed epithelium, with large granular masses made up of bacteria in all forms and in immense quantities. The mesenteric glands contained red blood-corpuscles and bacteria, and the adenoid tissue was burst or torn.

Monstrous Fetus.—Dr. KIDD presented a seven months' fetus, in which the lower extremities were united as low down as the heels; there were no genital organs, and no anus. Only one umbilical artery—a continuation of the abdominal aorta—existed. The pelvis was badly

developed. The bladder was in a rudimentary state. There were no kidneys. The Wolffian bodies were easily recognised. The intestine stopped short above the rectum. In the legs, the femoral vessels and cranial nerves were normal. All the muscles were normal, except the adductor magnus, which was common to both limbs. The case was one of symphysis, resembling, according to G. St. Hilaire, a syren, but more strictly a dolphin or seal. The mother of the fetus had had several abortions, and had, in addition, borne two living children.

Necrosis of Shaft of Tibia.—Dr. W. STOKES, jun., laid before the Society the bones of the leg of a man, aged 25, six feet four inches in height, of fair complexion, with blue eyes. When nine years old, the patient was suddenly attacked with severe pain near the tubercle of the right tibia. A discharge subsequently took place in this situation, and several pieces of bone came away. He then remained well for thirteen years. At the end of this time, a second similar attack occurred, the leg swelled and became livid, and the knee-joint was engaged. Ultimately, Dr. Stokes amputated the limb through the lower end of the femur. The bones, tibia and fibula, presented a remarkable example of necrosis, with numerous osseous sinuses, obliteration of the medullary canal, etc. The complete destruction of the knee-joint showed that the line of epiphysis did not always limit the extension of this disease.

CORRESPONDENCE.

THE CONTAGIOUS DISEASES ACTS.

SIR,—I have read with great care the two letters Dr. Parkes has recently addressed to you, but fail to find in them convincing evidence of the beneficial effects of the Contagious Diseases Acts. It is a noteworthy fact that the strongest assertions on this subject are always based upon figures, which are accessible only to those who produce them, and which it is absolutely impossible for independent inquirers to verify till long after the occasion requiring it has passed away for ever. The statistics which Dr. Parkes has brought forward in these letters are of this character, and the opponents of the Acts might justly, therefore, refuse to regard them. The Army and Navy Returns, laid annually before Parliament, are public property. To them the opponents of the Acts are willing to go for statistics on the question; and they conclusively prove that the British army is little, if any, the better for this painful legislation, and that the British navy is undeniably very much the worse.

I cannot, however, let Dr. Parkes's second letter pass without pointing out the many assumptions it contains. An inspection of monthly returns of admissions, furnished to Parliament at an early period of this controversy, showed long ago how very unsafe it was to estimate the number for a whole year from the number actually admitted in part of a year. Had the 58th Regiment arrived at Portsmouth at the same time that the 106th Regiment went to Parkhurst, the relative statistics might (and, in all probability, would) have been widely different. Then, the discussion of the possible numbers of admissions, the highest possible number and the lowest possible number, at the two stations, is fantastic in the highest degree. I venture to affirm that no professed statistician of ability and repute would endorse what Dr. Parkes has written under this head. Finally, the conclusion to which Dr. Parkes comes, that the difference that was actually observed was due to the presence or absence of the Acts alone, is entirely upset by the fact (which may be readily verified by turning to the Army Medical Report for 1872) that the stations where, in that year (being the last for which the official returns have yet been published), there were *no* admissions per 1,000 for primary venereal sores, were stations where there are *no* Acts—viz., Athlone, which yielded only 14 cases per 1,000, and Pembroke Dock, which did not yield more than 27; the two lowest under the Acts being Shorncliffe, which yielded 33 per 1,000, and Portsmouth, which yielded 40 per 1,000. Similar returns for gonorrhoea are not given, but there can be little doubt that, if they were, we should find that the stations where admissions for gonorrhoea were fewest were, in like manner, stations not under the Acts.

With regard to Dr. Parkes's first letter, it is sufficient to note that, in the face of the officially confessed failure of the Acts to diminish gonorrhoea, the great reduction in the number of admissions for that disease given in the figures respecting the Royal Engineers at Chatham, shows that the selection of that corps and the figures regarding it do not really present a sample of effects due only, or mainly, to the Acts.

I am, Sir, yours, etc., THOMAS WORTH, M.R.C.S.L.,

Late Surgeon to Nottingham Lock Hospital.

Peachey Terrace, Nottingham.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, March 4th.

Efficiency of Medical Practitioners.—Mr. ARTHUR MILLS asked the Vice-President of the Council whether, under the authority conferred by the Medical Act, 1858 (21 and 22 Vict., cap. 90), it was in the power of the Privy Council to establish one uniform test of efficiency for all medical practitioners in the United Kingdom, or whether further legislation would be required in order to effect that object.—Lord SANDON stated, that the Privy Council had not the power of enforcing an uniform test. But it might, if set in motion by the General Council of Medical Education, take measures for securing that none of the existing bodies empowered to grant certificates shall do so without securing a proper standard among the candidates by the process of refusing registration to the candidates certificated by any examining body in default.

Friday, March 5th.

Midwifery Practice.—Mr. JAMES asked the President of the Local Government Board, whether his attention had been drawn to the proceedings in the case of Elizabeth Ingram, as reported in the *Times* of March 1st; and whether it was his intention, in view of the circumstances the trial brought to light, to introduce any measure placing all persons practising in midwifery under more immediate supervision than at present, and giving power to the local authority, on the report of a coroner or other due cause shown, to suspend them from the exercise of their practice.—Mr. SELATIE-BOOTH said, that his attention had not been directed to the case otherwise than by the reports in the newspapers. It would appear that the prisoner alluded to was acquitted on the score of ignorance; so that if she had known the danger involved in her attendance, it is possible that she might have been liable to punishment. The subject had been before the Local Government Board, and very recently gave occasion to a correspondence between Mr. Selatie-Booth and the Secretary of State in connection with cases which occurred at Leicester and Wolverhampton. The question was a difficult one, and was under the consideration of the Government.

Monday, March 8th.

The Case of Miss Wood, the Shaker.—In reply to Mr. DILLWYN, Mr. CROSS stated that his attention had been called to the arrest, in the New Forest, of Miss Wood, a person alleged to be a lunatic, and that he had immediately put himself in communication with the Lunacy Commissioners. He ascertained that the certificate which had been given did not warrant her detention in a lunatic asylum, and that under the statute it might have been amended within fourteen days. He further communicated with the Lunacy Commissioners, and directed them to inquire into the matter, in order to ascertain whether her detention was really necessary. He was happy to say that that afternoon he had received a note saying that her discharge had been ordered.

Ship-Surgeons.—Captain PIM has given notice of his intention to ask the President of the Board of Trade whether it is true that both British subjects and foreigners have been and are still permitted to sign the articles of British ships as surgeons, and to serve on board such British ships as surgeons, who are not possessed of a diploma or other qualification required by Act of Parliament, and whose names do not appear on the medical list published under authority; and whether such persons are authorised to sign the usual and necessary professional certificates without their names having so appeared in such authorised medical list.

MILITARY AND NAVAL MEDICAL SERVICES.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Surgeon Gibson has been ordered to proceed from Cork for India, on duty.—Surgeon Bennett, M.D., has taken over medical charge of the troops stationed at Rocky and Spike Islands and Haulbowline from Surgeon-Major Croker.—Surgeon Thorburn has returned to Longford from leave, and resumed medical charge of the headquarters of the 8th (Royal Irish) Hussars.—Surgeon K. Harman, having reported himself to the surgeon-general for duty in Dublin, has been posted to the Station Hospital, Phoenix Park.—Surgeon G. P. Mackenzie, Bengal Medical Establishment, is allowed to proceed to Europe on medical certificate, in anticipation of furlough.—Surgeon W. S. Fox, civil surgeon, Vellore, has been appointed to officiate as secretary and statistical officer to the Surgeon-General, Indian Medical Department, during the absence on furlough to Europe of Surgeon-Major Bidie, or until further orders—

Surgeon-Major Jackson, C.B., late in medical charge of the 100th Canadians, has been appointed to the Brigade Depot at Paisley. Dr. Jackson served last year on the Gold Coast during the Ashantee campaign, and earned his C.B.

NAVAL MEDICAL SERVICE.—The recent promotions amongst naval medical officers have caused several changes; and it is generally believed that Dr. William Domville will be superseded at Plymouth by Deputy Inspector-General James Jenkins, C.B., now serving at Bermuda, who will be relieved by Deputy Inspector-General John Watt Reid; and that Deputy Inspector-General Ahmuty Irwin, C.B., will go to Port Royal, Jamaica, in place of Dr. Henry J. Domville, C.B.—Deputy Inspector-General of Hospitals and Fleets John Denis MacDonald, M.D., F.R.S., who has been promoted, has been reappointed to the *Duke of Wellington* for duties as Assistant-Professor of Naval Hygiene at Netley.

ARMY MEDICAL SERVICE.—List of gentlemen who competed successfully for appointments in Her Majesty's British Medical Service at the examination held at the University of London on Feb. 15th, 1875.

1. Le Motte, G. H. 1980	5. Mapleton, E. A. 1805
2. Dorman, J. C. 1985	6. O'Sullivan, D. 1840
3. Kellsall, E. W. 1980	7. Charlesworth, H. 1805
4. Chester, W. L. 1979	8. Sharpe, C. E. 1615

INDIAN MEDICAL SERVICE.—The following candidates for her Majesty's Indian Medical Service were successful at the competitive examination held at Burlington House on the 15th February, 1875. Forty candidates competed for twenty appointments. All were reported qualified.

1. Murray, R. D. 2500	11. Simmonds, W. A. 2130
2. Ranking, E. S. A. 2477	12. Macrae, R. 2095
3. Comins, D. W. D. 2339	13. Adams, A. 2070
4. Moran, J. 2274	14. Borah, Shihram 2050
5. O'Connor, P. F. 2250	15. Sturmer, A. J. 1993
6. Smith, N. H. 2180	16. Dane, A. H. C. 1950
7. Thomas, G. T. 2174	17. Greany, J. P. 1930
8. Beatson, W. 2173	18. Ferguson, J. C. 1920
9. Eate, T. E. L. 2165	19. Williams, B. H. 1920
10. Warburton, G. A. 2145	20. McCloghry, J. 1905

THE NEW NAVAL MEDICAL WARRANT.

SIR,—Naval medical officers owe to the disinterested advocacy of their claims by the *BRITISH MEDICAL JOURNAL* many of the alterations to their advantage which have taken place in the department of late years, and I am sure that all cordially thank you. With regard to the Naval Medical Warrant of February 1875, I hope you will permit me a few observations. That it is a step in the right direction is unquestionable, but that it has fallen far short of the requirements of the service, and what was reasonably expected is equally true. It would appear to be a mutilated warrant, originally ably conceived, and, had it been carried out in its entirety, would have stopped all reason for grumbling on the part of the department, and would have drawn a good class of men into the service to fill the fifty vacancies at present existing in the Surgeons' List. Stopping short as the new warrant does, I fear, it will have neither of these beneficial effects. I would, but with little comment, call the attention of aspirants for the Naval Medical Service to a few facts relating to the suggestions for improving the position of naval medical officers, as advocated by a committee of the British Medical Association, and draw a comparison between them and what has been granted by the new medical warrant.

1. Surgeons to rank with naval lieutenants of under eight years' seniority, as do naval instructors, etc.—This is granted in a way; surgeons, on entry, are to rank with naval instructors and chief engineer, but this should be marked, promotion from surgeons' to staff surgeons' list is practically at a standstill. The present seniors of the surgeons' list count fourteen years in the service, and the prospect before all entering is no promotion from the one list to the other until fifteen or sixteen years have been served in the junior capacity. The surgeon now entering will rank with a lieutenant of less than eight years' seniority all these fifteen years. No change, no improvement in position whatever. His compeer the lieutenant, made the same day as he joined, will, after eight years' service, rank with a major in the army; and the paymaster and naval instructor, after fifteen years, will rank with a lieutenant-colonel in the army, with choice of accommodation according to that rank. The surgeon, after fifteen or sixteen years' service, ranking with a lieutenant of under eight years' seniority, will, on promotion, but rank with a major; the paymaster and naval instructor at that time ranking with a lieutenant-colonel, and the lieutenant having been promoted to commander some years. The new

warrant has in this instance done nothing for the working men of the department, the staff-surgeons, and senior surgeons.

2. Alteration of Titles.—Where did the title of fleet-surgeon originate? It is used in the American navy to designate the surgeon of the flag-ship, and to distinguish him as the senior medical officer of a squadron, and was used in the same relation in our own navy at the end of the last and commencement of the present century, when some distinguished civilian physician was sent out with the flag-ship of the commander-in-chief of a large squadron, to advise him as to the health of his crew and sanitary condition of his squadron, when he was designated fleet-physician.

3. Rank of inspectorial grades: promoting them to rank with their correlatives, according to dates of respective commissions.—No mention made of this in the new warrant.

4. Substantive rank on retiring.—Like the above, no notice whatever is taken of this suggestion.

5. Promotion of surgeons: to be promoted to the rank of staff-surgeon after ten years' seniority, provided conduct and qualifications are satisfactory.—No provision whatever is made for the promotion of surgeons to the rank of staff-surgeons; the seniors on the surgeons' list are now fourteen years in the service. Promotion is at a deadlock, and fifteen, or even sixteen, years are to be looked forward to before promotion takes place, and during all that time the surgeon is to rank as on entry: viz., with the naval lieutenant of less than eight years' seniority. This should be well considered by those thinking to enter the Naval Medical Service.

6. Distinctive Uniform.—No change of uniform, as distinctive of completion of so many years' service, would appear to have been made in the new warrant. The surgeon, on entry, wears the same as the surgeon of fifteen years' service, or the staff-surgeon of nineteen years and eleven months. Under the old scale, the surgeon, having served actively six years, got a step in rank, and a corresponding change in uniform. Now, from date of entry until he reaches the position of fleet-surgeon, he wears the same as on the day he joined.

7. Retiring allowance of fleet-surgeons after twenty years' full-pay service.—The new warrant allows a retiring allowance of 15s. *per diem* after twenty years' full-pay service. This is exactly 1s. 6d. a day less than the half-pay earned after that number of years' service. This half-pay earned, viz., 16s. 6d. *per diem*, should be the minimum retiring allowance. Then, again, the number allowed to go annually is limited to ten, and even they may not be permitted to go, should their lordships not wish them. Practically, this so-called optional retirement is no boon at all, so with the retirement on 21s. after twenty-five years. No one can claim his retirement, as it is optional with the Admiralty whether they allow you to go or not.

8. Increase of full-pay; readjustment in some of the grades.—The young surgeon, on entry, has a fair pay; viz., a little over £200 *per annum*. But what are his prospects as he advances in the service? After fourteen years, he finds his annual income but £110 more than when he began life so many years before.

9. Hospital Charge-money.—On this subject, the new warrant says nothing. It is the only branch of the service where officers are in charge of establishments of great importance where charge-money is not allowed. In more than one instance, officers in charge are borne on the books of some ship, so that no allowance may be granted them, e.g., Portland Sick Quarters and Trincomalee.

10. Cabin Accommodation.—No mention of any alteration in this matter is made. Why should it be that a fleet-surgeon—often an old man 50 years of age and upwards—should be relegated to a miserable lower deck cabin, when the paymaster, probably many years his junior, or the chaplain, who might not have been born when the medical officer entered the navy, have cabins assigned to them on the main deck?

I am, etc., N. V. Z.

ARMY MEDICAL APPOINTMENTS.

DREW, Surgeon E., to be Surgeon-Major, *vice* H. Kendall, M.D., promoted.
 IGLES, Deputy Surgeon-General J. G., M.D., C.B., to be Surgeon-General, *vice* R. J. O'Flaherty, C.B., deceased.
 KENDALL, Surgeon-Major H., M.D., to be Deputy-Superintendent, *vice* J. G. Igles, M.D., C.B., promoted.

NAVAL MEDICAL APPOINTMENTS.

CLARK, Fleet-Surgeon W. H., to the *Undaunted*.
 O'CONNOR, Surgeon David, M.D., to the *Undaunted*.
 SMITH, Fleet-Surgeon W., M.D., to the *Unicorn*.
 EDNEY, Staff-Surgeon W., to the *Triumph*.
 ROUCKE, Surgeon M. G., }
 O'CONNOR, Surgeon D. W., } To the *Duke of Wellington*, additional, for Haslar
 RUSSELL, Surgeon A. W., } Hospital.
 WHATELEY, Surgeon G. F., }
 BRETON, Surgeon W., } To the *Royal Adelaide*, additional, for Plymouth
 O'CALLAGHAN, Surgeon J., } Hospital.

OBITUARY.

FREDERIC TURTON, L.R.C.P. LOND.

On the morning of February 24th, passed away a typical general practitioner. Frederic Turton was born in 1836, at Wolverhampton, the son of a general practitioner. Educated at the Grammar School of his native town, he gained his professional knowledge at the Birmingham School, being dresser at the General Hospital to Mr. Oliver Pemberton.

By the death of his father in 1861, at a comparatively early age, a large practice devolved upon him almost as soon as he became qualified; and, from that time, until a few months ago, he had been constantly and uninterruptedly engaged in the most arduous work. It is within the truth to say, that he sacrificed himself in the service of his patients. Soon after having become established, he was elected a member of the Town Council, and there devoted his energies to bringing before the public the sanitary defects of the town, and the means which were required in order to remedy them. During the violent epidemic of small-pox in 1871-72, he was urgent in his endeavours to press home all efforts likely to contribute to the public good, and carried his convictions to the issue of resignation of his office sooner than submit to an attempt to stifle some measures of sanitary reform. It is in a large degree due to this decided action, that Wolverhampton has become awake to the necessity of earnestness in this direction. He was one of the originators of, and secretary to, from its earliest formation, the Wolverhampton Friendly Medico-Ethical Society, which aims at promoting a healthy social and professional tone amongst its members. He was a great supporter of the attempt made to improve the rate of remuneration received by surgeons who hold clubs; and he always endeavoured to carry out the letter as well as the spirit of the report of the Committee of the Birmingham and Midland Counties Branch of the British Medical Association. He was always a prominent and valued member of the Association.

In his professional relations, an eminently conscientious man, he was in his private life a Christian gentleman. Always abreast of the times, both in literature and practice, he never forgot that "art is long", and only could not remember that "life is short".

Sound at all points in opinion, and able to carry out in practice, he was a man who brought comfort to the bedside of a serious case. By his professional brethren, and by his numerous patients, he was both respected and beloved. More cannot be said to his honour. Those who pen these lines feel that they have lost an honest and a loving friend, their sure hope being that he has reaped the reward he truly merited. He leaves a widow and five young children.

WILLIAM THORNHILL, M.B., F.R.C.S.I.

DR. THORNHILL died after a few hours' illness on February 26th, at Nenagh, Tipperary, where he had been summoned as a witness in a murder case, which was to be tried at the assizes; death arising from effusion on the brain. The deceased gentleman held the post of surgeon to the County Dublin Prison, Kilmainham.

WILLIAM SMITH, F.R.S.,

SENIOR SURGEON TO THE MANCHESTER ROYAL INFIRMARY, ETC.

MR. WILLIAM SMITH, whose death we briefly announced last week had lectured as Professor of Anatomy in Owens College since Christmas, but was absent for some days before his death, on account of not feeling quite well. On his return to Manchester on the 10th inst., from a visit to Brighton, he sent a message to the school, thanking Mr. Perrin (the medical tutor) for supplying his place in the chair of "General Anatomy and Physiology," and promising to resume it himself at once. Soon after this he died. Mr. Smith was to all appearance in good health when he entered his consulting room on Feb. 10th, to meet his patients at two o'clock. A few minutes afterwards, when stooping to examine the foot of a child, he sank to the ground and was unable to rise. Dr. William Roberts, residing immediately opposite, was sent for and came immediately. He found Mr. Smith at the point of death from an apoplectic seizure, and in a few minutes saw him expire. Mr. Smith has left a family to mourn him, but his loss will be much felt also in public, in the medical institutions, in the profession, and in the social life of Manchester. He had never sought a name for original research or as a contributor to medical literature, but as a professor and lecturer he was deservedly popular, and his high ability was beyond question. He had been a student in the same School of Medicine, in which he had taken a leading part as lecturer for the last quarter of a century. He became a

licentiate of the Apothecaries' Society in 1837, member of the Royal College of Surgeons in 1838, and for the last thirty years held a place in the front rank of the medical men of this district. His personal character and professional skill combined to make him one of the referees most in request in difficult cases occurring in a wide circuit round Manchester. He was the senior surgeon of the Manchester Royal Infirmary, and was also surgeon of the Cheetham College and the Manchester Schools for the Deaf and Dumb. He was in his 59th year, or thereabout. At nearly the same age, his father, a well-known papermaker in Manchester, died in a similar manner.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

SCHOLARSHIPS AND EXAMINATIONS FOR NATURAL SCIENCE.—The following is a list of the scholarships and exhibitions for proficiency in Natural Science to be offered at the several Colleges and for non-collegiate students at Cambridge during the present year.—*Trinity College*. One or more scholarships of £100, and one exhibition of £50. The examination will commence on March 30th. The scholarships are open to all members of the University of Cambridge who have passed the Previous Examination. The exhibition is open to persons under 20, who have not yet commenced residence at the University. Further information may be obtained from the Rev. E. Blore, Tutor of Trinity College.—*St. John's College*. One of the value of £50 *per annum*. The examination (in Chemistry, Physics, and Physiology, with Geology, Comparative Anatomy, and Botany) will commence on April 3rd, and will be open to all persons who have not completed a term of residence at the University, as well to all who have entered and have not completed one term of residence. In this College, Natural Science is on the same footing with Classics and Mathematics, both as regards teaching and rewards.—*Christ's College*. One or more in value from £30 to £70, according to the number and merits of the candidates, tenable for three-and-a-half years, and for three years longer by those who reside during that period at the College. The examination will be on April 6th, and will be open to the undergraduates of the College, to non-collegiate undergraduates of Cambridge, to all undergraduates of Oxford, and to any students who are not members of either University. The candidates may select their own subjects for examination. Further information may be obtained of John Peile, Esq., Tutor of the College.—*Gonville and Caius College*. One of the value of £60 *per annum*. The examination will be on March 18th, in Chemistry and Physics, Zoology with Comparative Anatomy and Physiology, and Botany, with Vegetable Anatomy and Physiology. It will be open to students who have not commenced residence in the University. There is no limitation as to age. Further information may be obtained from the Tutors. Scholarships of the value of £20 each or more are offered annually, for Anatomy and Physiology, to members of the College. Gentlemen elected to the Tancred Medical Studentships are required to enter at this College; the studentships are five in number, and the annual value of each is £100. Information respecting these may be obtained from B. J. L. Frere, Esq., 28, Lincoln's Inn Fields, London.—*Clare College*. One of the value of £60 *per annum*, tenable for two years at least. The examination (in Chemistry, Chemical Physics, Zoology with Comparative Anatomy and Physiology, Botany with Vegetable Anatomy and Physiology, and Geology) will be on March 16th, and will be open to students intending to begin residence in October.—*Downing College*. One or more of the value of £60 *per annum*. The examination (in Chemistry, Comparative Anatomy, and Physiology) will be on April 6th, and will be open to all students not members of the University, as well as to all undergraduates in their first term.—*Sidney College*. One of the value of £60 and one of the value of £40 *per annum*. The examination (in Heat, Electricity, Chemistry, Geology, Zoology and Physiology, Botany) will be on April 6th, and will be open to all students who intend to commence residence in October.—*Emmanuel College*. One of the value of £70. The examination on March 24th will be open to students who have not commenced residence.—*St. Peter's College*. One scholarship of the value of from £40 to £80, according to the attainments of the candidate. The examination on April 6th will be in Botany, Chemistry and Chemical Physics, Geology, and Comparative Anatomy and Physiology; but no candidate will be allowed to be examined in more than two of these subjects. It will be open to all students under twenty-one years of age who can obtain permission to become members of the College. Application must be made before March 20th to the Tutor.—*Non-collegiate Students*. An exhibition each year is given by the Clothworkers' Company, value £50 *per annum*, tenable for three years. Examination about Christmas, open to non-

collegiate students who have commenced residence in the October Term, and to any who have not commenced residence. Information to be obtained from the Rev. R. B. Somerset, Cambridge. Although several subjects for examination are in each instance given, this is rather to afford the option of one or more to the candidates, than to induce them to present a superficial knowledge of several. It is expressly stated by some of the Colleges, that good clear knowledge of one or two subjects will be more esteemed than a general knowledge of several. Candidates, especially those who are not members of the University, will in most instances be required to show a fair knowledge of Classics and Mathematics, such, for example, as would enable them to pass the Previous Examination. There is no restriction on the ground of religious denominations. Further information may be obtained from the Tutors of the respective Colleges. The names, with certificates of character, date of birth, etc., must be sent to the Tutor of the College, in each case, several days before the examination. Some of the Colleges will give additional scholarships if candidates of superior merit present themselves; and other Colleges than those here mentioned, though they do not offer scholarships, are in the habit of rewarding deserving students of Natural Science.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examinations in the science and practice of medicine, and received certificates to practise, on Thursday, March 4th, 1875.

Barnes, Edwin, Accrington, Lancashire
Bass, Charles William, Barnsley, Yorkshire
Cumming, Hugh Gordon, Exeter
Clutton, Henry Hugh, St. Thomas's Hospital
Gill, John, St. Thomas's Hospital
Henwood, John Davey, Milbrook, Cornwall
Hind, Henry Joseph, Twickenham
Phillips, Charles Henry, Bury, Lancashire
Scott, Alexander Thomas, Camden Town Road, N.W.
Thompson, Alfred, London Hospital
Weddell, William Henry, Stamford, Lincolnshire

The following gentleman also on the same day passed his primary professional examination.

Tyrell, Frederick, St. Mary's Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

BANTRY UNION—Medical Officer for the Workhouse. Salary, £50 per annum. Applications to be made on or before the 24th instant.—Medical Officer for the Bantry Dispensary District. Salary, £100 per annum, and fees. Applications on or before the 24th instant.

BECKETT HOSPITAL AND DISPENSARY. Barnsley.—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.

BIRKENHEAD BOROUGH HOSPITAL—Senior House-Surgeon. Salary, £100 per annum, with board. Applications on or before the 22nd instant.

BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.

BRISTOL LUNATIC ASYLUM—Assistant Medical Superintendent.

CHARING CROSS HOSPITAL—Resident Medical Officer. Applications on or before the 24th instant.

CLIFTON UNION—Medical Officer for No. 3 District. Salary, £25 per annum.

COVENTRY AND WARWICKSHIRE HOSPITAL—House-Surgeon and Dispenser. Salary, £100 per annum, with board, lodging, and attendance. Applications to be made on or before March 25th.

DEVON AND EXETER HOSPITAL—House-Surgeon. Salary, £150 per annum, with board.

DORSET COUNTY HOSPITAL—House-Surgeon. Salary, £70 per annum, with £10 additional as Secretary. Applications to be made on or before March 18th.

DOVER UNION—Medical Officer for the St. Mary's District and the Workhouse. Salary, £180 per annum.

DURHAM COUNTY ASYLUM—Assistant Medical Officer.

FETTERCAIRN, Parish of—Medical Officer and Public Vaccinator. Apply to Colonel M'Invoy, Chairman of the Board, The Burn, Brechin, not later than the 27th instant.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST—Resident Clinical Assistant. Applications on or before April 5th.

KINGSTON, Jamaica—Two Medical Officers for the Public Hospital.

LIVERPOOL ROYAL INFIRMARY—Resident Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications on or before April 10th.

MANSFIELD UNION—Medical Officer for the First District, and the Workhouse. Salary, £50 and £40 per annum, respectively.

MILFORD UNION, co. Donegal—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.

POOLE UNION—Medical Officer for No. 2 District. Salary, £60 per annum.

ROYAL EDINBURGH ASYLUM—Assistant-Physician.

ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road—Physician.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.

ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.

ST. THOMAS'S HOSPITAL—Assistant Obstetric Physician.

SOUTH ESSEX DISPENSARY—Surgeon.

SOUTH SHIELDS UNION—Medical Officer for the Westoe District. Salary, £40 per annum.

STRATTON UNION—Medical Officer for No. 3 District. Salary, £70 per annum.

TORBAY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.

WEST NORFOLK AND LYNN HOSPITAL—Resident Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 30th instant.

WEST BROMWICH DISTRICT HOSPITAL—Salary, £30 per annum, with board, lodging, and washing. Applications on or before the 22nd instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

INGLIS, Thomas, L.R.C.P. & S. Edin., has been appointed an Assistant Physician at the Royal Edinburgh Asylum.

JEPSON, Edward, M.R.C.S., appointed Honorary Surgeon to the Durham County Hospital, *vice* E. C. Jepson, F.R.C.S., resigned.

NEWBY, C. H., M.R.C.S., L.R.C.P. Lond., has been appointed House-Physician at St. Thomas's Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

SOLOMAN.—On February 24th, the wife of Charles Solomon, L.R.C.P. & S. Edin., Skirlough, of a son.

MARRIAGE.

LEE—SHAW.—On February 25th, at St. James's Church, Slaitwaite, by the Rev. Canon Hulbert, M.A., Vicar of Almondbury, assisted by the Rev. C. A. Hulbert, Vicar, Francis Boynton Lee, M.R.C.P., F.A.S.L., of the Elms, Heckmonwike, to Anna Marie, daughter of Richard Shaw, Esq., of Broadfield House, Slaitwaite. No cards.

DEATH.

HARDEN, Charles, M.R.C.S., formerly House-Surgeon to University College Hospital, aged 43, on February 19th.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8 P.M. The President's Address; after which Dr. Jagielski will read a paper on Spuremetry, illustrated by a new instrument.

TUESDAY.—Pathological Society, 8.30 P.M. Mr. Hutchinson: Skin-Disease in an Infant, in association with Disease of Nervous System (living specimen). Mr. Earwell: Myeloid Sarcoma of Head of Humerus. Mr. Barwell: Mixed Tumour of Wrist. Mr. Godlee: Blood-Cyst found in a Sarcoma. Mr. John Wood: Tumour of Scapula. Mr. Knowsley Thornton: Ovarian Cyst with Papillomatous Growths in its Interior. Mr. Knowsley Thornton: Cancer of Ovary. Dr. Julius Pollock: Worm in Right Ventricle of Heart of Dog. Dr. Crisp: Specimen of Tubercle in Pheasants. Dr. Crisp: Cancer in Common Fowl. Dr. Crisp: Brain and Cord of Fowl. Mr. Maunders: A Fatty Tumour. Dr. Duka: Dry Gangrene of Lower Extremities. Mr. Fairlie Clarke: Prolapsus Linguae.

THURSDAY.—Harveian Society of London, 8 P.M. Dr. Cheadle, "Case of Duchenne's Paralysis, and Case of Morphaea Alba"; Mr. Lennox Browne, "The Treatment of Simple Catarrh of the Nose, Throat, and Ear".

FRIDAY.—Medical Microscopical Society, 8 P.M. Ordinary Meeting.

DONATION.—The Mercers' Company have made a grant of fifty guineas and an annual subscription of ten guineas in aid of the funds of the Royal National Hospital for Consumption located at Ventnor.

PRESENTATION.—Mr. Henry Brietcke, late assistant-surgeon to Portsmouth Convict Prison, was last week presented with a handsome marble and gilt twenty-one day clock, upon his removal to Millbank. There was a large attendance at St. John's school-room, Portsea, to witness the presentation, and the meeting was presided over by Mr. Alexander, deputy governor of the prison. The clock bore the following inscription: "Presented to Henry Brietcke, Esq., L.R.C.P., M.R.C.S., etc., by the officers of Her Majesty's Convict Establishment, Portsmouth, in appreciation of his kindness and attention to them and their families during his short stay amongst them, and as a token of their esteem and of regret at his departure. February, 1875." The chairman, and the Rev. Mr. Innes, chaplain to the Portsmouth Establishment, both spoke in highly laudatory terms of Mr. Brietcke's skill and attention; and that gentlemen having spoken in reply, the meeting terminated.

PRESENTATION.—The members of the Loyal City of Limerick Lodge of Independent Order of Odd-Fellows, lately presented J. Elmes, M.B., with an address, and a number of standard works in literature, as a public expression of their regard, and for having acted as their physician for the last twenty years, being ever "sedulous, kind, and skilled."

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAYSt. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

MR. H. ORFEUR (Loddon).—C. J. Welder, Esq., 1, Upper Berkeley Street, W. (for Finance); G. Hett, M.D., 1, Ledbury Road, Bayswater, W. (for Cases). *

THE EFFECTS OF THE CONTAGIOUS DISEASES ACTS.

SURGEON HAMILTON (Chatham) writes to us:—"I can say of my own personal knowledge that venereal disease is not nearly so prevalent, and nothing like so virulent as it was here in 1866. When I joined the service here in that year, the venereal inspections of the troops were carried out weekly, disgusting to the officers who had to make them, and degrading to the men who underwent them; and I also affirm both syphilis and gonorrhoea existed to a far greater extent than they now do.

"It is the unqualified opinion of every medical officer to whom I have spoken on the subject at this station, that not only is venereal disease (especially syphilis) much less frequent, but that it is of a milder type, and secondary disease is becoming positively rare. We never see any of those miserable cases of tertiary disease, with destruction of bone that used to be so common; and though there are still a good many cases of what ought really to be called 'venereal sores', there is very little true syphilis.

"Gonorrhoea also is much milder in its type, and indeed is often more of a gleet, even in men who have a first attack—such as would be contracted from a woman with leucorrhoea. Last year I was quartered at Hounslow, and was attached to the Carabiniers for duty. There were present at head quarters about four hundred men, and I have seen nearly as many cases of primary disease in that small number, as we have now in Fort Pitt, out of a garrison of nearly 3500 men. Hounslow is not only unprotected, but is within easy reach of London by rail, while Chatham is under the 'Acts,' and they are efficiently worked."

At the commencing of the report of the Pathological Society in the JOURNAL of March 6th, it was stated that the President exhibited a photograph of a case of "Molluscum Contagiosum." It should have been "Molluscum Fibrosum."

PROVIDENT DEPARTMENT OF HOSPITALS.

SIR.—The Governors of Scarborough Dispensary, of which I am house-surgeon, are considering the advisability of charging each patient a small sum on admission. Can any of your readers kindly give me particulars of similar institutions, and of the mode in which the funds so raised are applied? I shall be greatly obliged for any reports or rules of Provident Dispensaries.

I remain, Sir, yours truly,

Dispensary and Accident Hospital, Scarborough, J. A. CALVERT.

March 6th, 1875.

INQUIRER AND A MEMBER.—We could not recommend any one to tender for an office in the gift of a local authority, on terms which had been rejected as insufficient by the local medical men. Such a course would be open to unpleasant comment.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than Thursday, twelve o'clock.

THE REDDITCH MEDICAL AID ASSOCIATION.

We have received a second letter from Mr. W. Aston, the Secretary of this Association, in which he tells us that they have now obtained the support of many influential gentlemen in the neighbourhood, who promise pecuniary aid as well as the weight of their names. If, as Mr. Aston says, this has been partly the result of our comment, we are glad of it, for it will certainly somewhat improve the position of any medical man who takes office under the Association. We have, however, with considerable difficulty succeeded in obtaining a copy of the *Redditch Indicator*, for September 26th, 1874, which contains the original proposal for the formation of the Association, and the information which we derive from it only confirms us in our previous objections. We have always advocated "self-help" among the working-classes, and we are prepared to welcome a variety of institutions founded upon this principle. But, at the same time, we are bound to keep a watchful eye upon the interests of our profession; and it appears to us that the scheme proposed for Redditch is open to most serious drawbacks. The medical officer will be entirely under the control of a committee wholly composed of men belonging to the working-classes. They agree "to pay him a fixed annual salary, with certain specified sources of increase to it; they also find him a house, pay rent, rates, etc., etc.; cab-hire, superintend the fitting up of the surgery, purchase of drugs—in fact the whole governing power is invested in a number of representatives of the various societies in the Association." Such is the model which the Redditch Association holds up to itself—and a tight jacket it is likely to be for the surgeon! But not to speak of other annoyances, he will have no control over the members admitted to the various benefit societies, whom he will be bound to attend. We all know that such societies not unfrequently enrol persons who are in the receipt of high wages, and who could abundantly afford to pay much more for their medical attendance than the trifling capitation fee which the doctor is to receive; and thus he may not improbably find himself in the unenviable position of having to treat for a few shillings a year, those who could well afford to obtain for themselves the best advice in Redditch on the ordinary terms of business. In these days of excessive competition, it is not perhaps surprising that the terms offered by the Redditch Association should meet with a response; but we should fail in our duty if we encouraged any young aspirant to medical practice to enter upon a field which seems to be already fully occupied, and to place himself in a position such as we have described. To do this would be, we believe, alike prejudicial to his own ultimate interests, and inimical to that *esprit de corps*, which ought to lead every member of the profession to uphold its dignity and independence.

P. K. S.—The tracts of the Provident Knowledge Society can be obtained at the office, 112, Brompton Road, London. S.W.

THE CASE OF MR. PEACOCK.

SIR.—The case of Mr. E. Peacock is not unique. Dr. Thatcher, an eminent accoucheur of Edinburgh, in 1845, used to relate a similar case in his Lectures, of a medical man who, under the like circumstances, removed, if I remember aright, nine feet of intestines from a patient. He was tried for manslaughter, and escaped under some such plea as "good intentions."

Anyone wishing to know more about the case, would find a clue to it in the fact that the prisoner was defended by Mr., afterwards Lord Chief Justice, Denman.

I am, yours faithfully,

Bonamy House, Lavenham, March 6th, 1875

W. M. WHITE, M.D.

FILTERS.—Mr. Herbert Morgan (Lichfield) writes:—Will some one who knows the subject practically, state what is the best filter for ordinary household use, and whether it will remove all impurities.

SYPHILITIC INFECTION.

SIR.—In answer to Dr. Brown's query in the JOURNAL of February 20th, as to whether syphilis can be conveyed by the use in common of cups, etc., I beg to refer him for affirmative answers, both direct "and indirect," to the authors quoted below. "Trousseau refers to the danger of infection from others besides the nurse, and speaks of the child as 'being as able to transmit as it has been to receive infection.' Drysdale says: 'All such ulcers and patches, on whatever part of the body they are situated, are full of contagious secretions.' Hirsch, in speaking of the spread of various forms of secondary syphilis, says: 'The spread of the disease, as is self-evident from the exceedingly frequent absence of affections of the genital organs, takes place not only through sexual connection, but also by other ways, of which the common use of eating and drinking vessels, clothing, etc., may be mentioned.'

It appears to me very probable that the strong dislike in decent society to drinking out of the same cup or glass has arisen out of the occasional occurrence during past centuries of transmission of syphilis by such means.

One case has been related to me by a medical man, in which several officers in a regiment were attacked by syphilis without themselves being able to account for it. But one brother officer had a cornet-a-piston, on which he often practised; and it transpired that he had syphilis. The others had occasionally made hideous noises with the instrument when visiting him, and so had caught the disease.

I am sorry that I cannot give any better particulars or dates; but it is just possible that this letter may meet the eye of the medical officer in whose regiment the circumstance occurred, who will, perhaps, be so kind as to confirm or correct what I have stated as it was told to me.—I am yours respectfully,

Cupar Fife, February 20th, 1875.

W. MUNRO, M.D., C.M.

* Niemeyer's *Textbook of Practical Medicine*, vol. ii, p. 696. CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

CASE OF INTENSE ACIDITY OF STOMACH.

SIR,—I am at the present time attending a lady who is suffering from aortic regurgitation, with, I fear, some mitral affection. In addition to the heart-disease, there is intense acidity of the stomach, so that after food great pain is produced. This complication will not yield to treatment. I have tried every known remedy in the materia medica, and all to no purpose. As this very painful and distressing symptom prevents her taking proper support, I should like to meet with something which would act upon it. I should feel greatly obliged if some gentleman who has had experience in such a case would impart to me, through the JOURNAL, his method of treatment at as early a date as possible. I may mention that my patient's heart was deranged through an attack of rheumatic fever several years ago.—I am, etc.,
L.R.C.P. EDIN.
March 6th, 1875.

ALPHA (Dover).—1. The option of granting superannuation allowances rests with the guardians, whose practice varies very much in the matter. 2. Vaccination grants are made on the report of the medical inspectors of the Local Government Board.

WHOOPING-COUGH.

SIR,—There is at present a general diffused epidemic of whooping-cough, and I think it may be useful to suggest a remedy which I have found beneficial—bromide of potassium. It allays the violence of the paroxysms, and cures in a few weeks, sometimes less. I generally combine it with the bicarbonate, and with tincture of hyoscyamus, in camphor mixture.—Yours truly,
70, Pembroke Road, Clifton, Bristol, March 8th. W. SMITH, Surgeon.

AN APPEAL.

SIR,—Mr. Merryweather, M.R.C.S., L.S.A., of 14, Colville Road, Bayswater, had suffered from several severe attacks of acute rheumatism, which left him with disease of the heart, and other serious results. Having a wife and five children to provide for, he very often followed his professional duties in much suffering, and when rest was essential for his personal welfare. But his health failing still more seriously, he became unable to continue his work at all regularly, and his practice of course greatly diminished, so that after his decease (and he died literally in harness, for he had visited, though with much difficulty, a patient within two hours of his death) it was found that his assets were barely sufficient to meet his liabilities, and to pay the expenses of his funeral. It is very probable, indeed, that his anxieties respecting his pecuniary position still further undermined his constitution and accelerated his death, which took place on the 11th of last month.

His widow is a thorough lady, of high class education, and of great energy of character, and if enabled to commence a school, has full confidence in being able to provide for herself and children. Some friends of her late husband, and of herself, well knowing these circumstances, and feeling sure that the case is one of the best kind—that of a widow, striving to help herself and to bring up her children as her husband would have wished—desire to raise a fund to enable Mrs. Merryweather to take a house for the purpose named, for the duties of which she is fully qualified, having been similarly engaged previously to her marriage. They feel certain that aid now given, will not only be of temporary use, but of permanent value.

The case has been examined by the Committee of the British Medical Benevolent Fund, and they have, under the special circumstances, made to the proposed fund the unusually large grant mentioned below.

As I am thoroughly sure that in this instance gifts will be well bestowed, I shall have much pleasure in receiving and acknowledging any donations which may be kindly contributed to this fund; as will also Dr. Atwood, 129, Ladbroke Grove, Notting Hill, London, W.; and thanking you much for allowing this appeal to appear in your pages.

I am, Sir, yours very faithfully,

CHARLES J. HARE, M.D. Cantab., F.R.C.P.

57, Brook Street, Grosvenor Square, W., March 8th, 1875.

SALIVARY GLAND. complains that, after receiving letters requiring an answer, he is annoyed by finding a postage stamp enclosed, the corner of which has been licked and stuck on a corner of the communication. This he thinks a very dirty and objectionable proceeding on the part of his patients, who might be suffering from some syphilitic affection of the mouth. We entirely agree with him, and suggest that the proper and equally safe plan would be to make two slits or cuts in the paper, and then introduce between them the stamp or stamps.

DR. SIMPSON.—The celebrated Oliver Goldsmith was examined at Surgeons' Hall, in the Old Bailey, on December 21st, 1758, and "plucked". In the books of the College of Surgeons, amidst a long list of candidates who passed, occur "James Bernard, mate (surgeon's) to an hospital, Oliver Goldsmith found not qualified for ditto." The examiners, or as they were then termed the Court of Assistants present on the occasion were, Christopher Fullager (who presided instead of Mark Hawkins, the master); Edward Nourse, warden; and Messrs. Singleton, Girdle and Roule, examiners. The fee for examination for Hospital Mate was only half-a-guinea. We believe Mr. South has been long engaged in writing a History of the Royal College of Surgeons.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

PROVIDENT MEDICAL CLUBS.

SIR,—In answer to Mr. Lee Jardine's short note of inquiry, I would beg to call his attention, and the attention of all medical men who have much to do with the poorer class of trade and agricultural labourers, etc. (their wives included), to the Rules and mode of working of the "National Deposit Friendly Society", which Rules may be obtained of Mr. F. Whitburn, Guildford, Surrey. The Society is flourishing, and its conduct towards the medical profession is honourable and most satisfactory. "Surgical cases are paid for at the same rate as under the Poor Law regulations"—Medical Cases: Visit, with medicine for two days, 2s. 6d., ditto beyond three miles, extra per mile 6d. Members entitled to over 2s. daily sick pay, extra for every 1s. above 2s. per visit, 6d.; attendance at Surgery and Medicine, 1s. 6d.; fresh supply of Medicine for two days, 1s. Members of this Club are at liberty to send for any duly qualified Medical Practitioner who is willing to attend them on the terms of the Society, and is approved by the County Sub-committee; but unless the nearest duly qualified medical practitioner is employed, the extra mileage must be paid by the member out of his or her own deposit. I have now no pecuniary interest in any club or dispensary, neither do I wish to have; but, from personal experience, and from inquiry which I have lately been making into various kinds of clubs and provident societies, etc., I have been compelled to come to the conclusion that most of the systems now in vogue for the relief in sickness—medical aid, provision for old age, funeral fees, provision for widow and orphans of the lower class of trade and poor, etc., have in them much that is radically wrong. Now how far can our profession be held responsible for the existing condition of things? (I hope that some practitioners who are largely engaged in club work will be able to answer this question.) Legislation may do much for these societies, but, depend upon it, the moral weight of professional opinion will do more than anything else towards founding institutions on a broader and sounder basis, and in working the necessary reforms in those that are established on fairly good principles (such as the club I have previously held out as an example).

Now that system is a good one which adopts the principle that every member of a club shall be considered by the club and the profession as a private patient, to be cared for and treated as such according to a tariff carefully understood and agreed to by the profession, provided the patient be allowed to call in his own medical man as any other private patient would do.

The system that allows a medical man to enter into a contract to attend each member of a club at 4s. or any other number of shillings per member per annum is wrong in principle and derogatory, inasmuch that if free from sickness the members are paying money for attendance which they have not had, and the medical man is really receiving money for which he has not done anything, and to which he has no moral right; on the other hand, if the sickness be great, the subscriptions are not an adequate remuneration, and the medical man is acting unjustly to himself, and robbing his family. Why? Because he has not the courage to stand up against a system, which can pay for work not done, but will not pay for work actually done, and which finally does afford to share out or otherwise place money, and put a large sum of money into the pockets of the publicans, a part of which sum honestly and fairly belongs to the profession, and to those members of the profession who are most hard worked, worst paid, and at the same time the most to be admired and highly appreciated. I have to thank you for having on two occasions noticed in the JOURNAL the endeavour I have been making to bring about a reform with regard to the mode of supplying medical aid to the societies of this part of the wealth of Kent and Sussex, by writing some letters on the subject to the county papers, copies of which letters have been duly posted to you for censure, but have received your commendation. The members of the association residing in my immediate neighbourhood intend shortly to meet and discuss the subject of medical aid, when a series of resolutions will be put to the meeting. We trust to have a pleasant social gathering. I shall be glad to hear from members residing near here what will be the most suitable time and date for fixing the meeting.—I am, yours faithfully,

W. MILSTED HARMER, M.R.C.P. EDIN.

Hawkhurst, Kent, March 1st, 1875.

THE LIVERPOOL MEDICAL STUDENTS.

A STUDENT writes to complain of the abolition of six exhibitions valued at £31 10s., which had been announced in the last prospectus of the Liverpool Royal Infirmary School of Medicine as being open to competition to third year's students at the Royal Infirmary. The Committee have suddenly resolved to withdraw these exhibitions without notice, and to substitute instead six qualified house surgeons, for periods of six months, without stipend. The ground of complaint is the suddenness with which this thing has been done. Several students have been working very hard for the competition, and it is hard to be told that the exhibitions are to be done away with. The students, he stated, entertain thoughts of proceeding against the Committee for breach of contract, though they have no doubt that the change will ultimately be a benefit to the institution. They contend, however, that this step should not have been taken until due notice had been given in the next prospectus.

F.R.C.S.—It is a mistake on the part of the *Medical Directory*. Mr. Hilton's appointments as President of the College of Surgeons and of the Pathological and New Sydenham Societies should have been placed under the "late" appointments held by him.

MATERNAL IMPRESSIONS.

SIR,—The following case, bearing upon the influence of maternal mental impressions upon offspring, I give without comment, thinking it may be useful to those gentlemen who take a special interest in this question.

On June 12th, 1867, I was sent for to see a child aged two years, which my assistant, on his arrival, found to be dead. A large hand-barrow had fallen on its head, instantly killing it. The only marks of injury observable were slight bruising over the left temple and injury to the mouth—the teeth being, as the mother described to me a few days ago, "knocked up into its gums". I distinctly recollect that there was injury to the mouth. The mother, who was pregnant, went to the full period, and was attended by myself on October 10th—i.e., four months after the violent death of her child. The infant was still-born, and had a most frightful hare lip, with the palate nearly entirely wanting. Of course, the woman herself and her neighbours had no doubt as to the cause of the malformation. The two children she had borne prior to this were in every respect free from blemish. Since that time, I have attended her three times in confinement. The first two of

these are sound healthy children; the last, born three months ago, was again frightfully disfigured by hare-lip and deficient palate, and only lived some hours.

I have never been a total disbeliever in the possibility of mental impressions affecting injuriously the fetus *in utero*, and this case did certainly, to some extent, tend to dissipate any doubt; and yet the occurrence of the second case of hare-lip so long after the accident, as well as the birth of two sound children in the interval, are circumstances which would encourage us to disbelieve in the operation of maternal impressions in this case, and to consider the malformations as merely coincidental. The fact, too, of the woman being so far advanced in pregnancy as five months, seems to me somewhat unfavourable to the opinion that there existed here cause and effect, for it seems probable that these mental impressions would diminish in their action in a ratio corresponding with the growth of the fetus, and that during the very early months such influences would be more operative than after the perfect development of the fetus.

The temperament of the mother, it is worthy of remark in this case, would be peculiarly conducive to such a result, for she is of a moody and affectionate nature, capable of deep and lasting grief; and, when lately confined, assured me that the calamity which befel her so long ago is ever present on her mind—Yours truly,
Duneden House, Jarrow-on-Tyne, Feb. 1875. ROBT. HUNTLEY.

M.D. (Cheltenham).—The late Lord Chief Justice Denman, writing from Cheltenham to his friend Merivale, says: "Before I left London, the jaundice had worn itself from pure gold to counterfeit silver; and Baillie has sent me here to wash away the last remains of gilt. I love the place, and find the waters most beneficial."

MEDICAL TITLES.

SIR.—It is my purpose to bring before the Annual Meeting of the South-Eastern Branch, a proposition to the effect: "That in the opinion of this meeting, the title of Doctor ought to be accorded to all registered members of the profession, as an act of courtesy, and in agreement with general usage on the part of the public."

I send this announcement to the JOURNAL, in the hope that similar proposition will be brought forward at the Annual Meeting of every branch, so that the members of our Association may have an opportunity of voting on the subject. Argument has been well-nigh exhausted—let us express our sentiments by voting.

Yours truly, FREDERICK JAMES BROWN, M.D.

Rochester, March 9th, 1875.

SIR.—Allow me to point out a slight fallacy in Dr. Partridge's argument with regard to the assumption of the title "Dr." He brings, as an analogous case, the assumption of "Rev." by ministers of all denominations, and of "Esq." by people other than barristers. There is not the slightest analogy. "Rev." and "Esq." even when granted to those to whom they are legally applied, are honorary and courtesy titles; they do not indicate any degree whatsoever. On the other hand, "Dr." is undoubtedly the sole property of an University, and implies that a man is a member of the University whence his degree was conferred. Had Dr. Partridge brought as an analogous case the claim of all clergymen (which happily does not exist) to be called "Dr.", understanding thereby "D.D."—an *University title* which they do not possess—there might have been something in his argument. If people would consider the question comparatively, and come to understand that there are other faculties, such as Law and Divinity, in which the title Dr. exists, they might arrive at some satisfactory conclusion. There may or may not be a decided advantage in the guarantee of an University that one is a fit and proper person, etc. But, be that as it may, the fact remains, that the degree itself is a grade in some faculty cultivated by an University, and has nothing whatever to do with medicine in the abstract. On the other hand, I quite agree with your correspondent "Pisistratus" that, if "M.B." are allowed the title by courtesy, "L.R.C.P.s" might also without unfairness have that privilege accorded them—Yours faithfully,
CANTAU.

Emmanuel College, February 26th, 1875.

SIR.—There are two points of injustice towards L.R.C.P.s, which amongst the various views set forth are liable to be lost sight of.

1. When I obtained my L.R.C.P., by thorough examination, and not in a year of grace, there was no question as to the title of Dr., for it had always been attached to it, and hence I had no compunction whatever in placing Dr. on my brass plate, etc.; but after many years, a set of newly fledged M.D.s took upon themselves to create a commotion and question the rights of L.R.C.P.s, already established by custom, to say the least of it. To tell me, therefore, to take Dr. off my door plate after having had it there for years is, under the circumstances, a piece of presumption, but quite characteristic of the spirit in which this question has been argued.

2. After completing my medical education at a school "whose lectures, etc., were recognised by the London University," I presented myself for the matriculation examination; but imagine my consternation at being informed that, simply because I had not passed the matriculation *before* I commenced my studies, my four years' medical education would count for nothing, and that if I wanted a degree, I must go back to College and study four years more. I need hardly say that I declined the honour, and so went without the M.D.

I have, however, the pleasure of being, yours,

L.R.C.P. and F.R.C.S.

SIR.—There is one practical result that should follow the publication of the numerous letters in your JOURNAL, respecting medical titles. Instead of quarrelling about empty honours, let us advocate the establishment of a *representative* Medical Council or Faculty of Medicine and Surgery, where *all* will take the degree of Licentiate of Medicine and Surgery, and after this, let them have as many degrees from Colleges, Halls, and Universities as they please, but let us have *uniformity* in the United Kingdom, as regards the one *essential* examination. There is one fact respecting the London College of Physicians that should be noticed. This College only admitted those to its membership who had the degree of M.D. from an University, the College not being able to confer this title. To obviate this difficulty, some men bought their degrees at foreign Universities, and then were admitted to the examination in Pall Mall.

Yours obediently,

EDWARDS CRISP, M.D.

29, Beaufort Street, Chelsea, February 24th, 1875.

SIR.—In the JOURNAL for January 10th, 1874, at page 53, is a notice of the annual meeting and sixth anniversary of the St. Andrew's Medical Graduates' Association. "A great portion of the report," the notice mentions, "was occupied with the

steps taken in reference to the M.D. degree, and the interviews on that subject with the Lord President of the Privy Council." It then went on to state that the General Council of the University, held in the hall of the United College, at St. Andrew's, on the 27th of March last, had resolved that a Committee of the General Council be formed in London, to watch over the interests of the University, in the event of any action either in Parliament or otherwise.

What I would suggest, Sir, is that this Committee, if it be really in existence in London, and has the power of speaking and acting on behalf of the University, come now to the front, and backed by the support and co-operation of the very many medicals desiring the M.D. degree, do now again fairly and earnestly pray of the Privy Council power to alter and amend the present regulation of St. Andrew's University, whereby only ten medical practitioners of forty years and upwards are admissible by examination without residence, by substituting an unlimited number, and any age, providing they have done fully four years study at a British Medical School, and five years' general practice since their registration. By making the examination sufficiently severe, would prevent inferior practitioners gaining an honourable title that good men would be proud of.

Some of your correspondents seem to think we are anxious that the M.D. should be conferred upon us in return for a minimum amount of knowledge and a good fee. Sir, I for one will never possess a degree on such terms—I desire a thoroughly good examination in every sense of the word. The more severe the examination, the more pride I shall have in passing it, and the more credit will the degree be to me.

Many thanks for your two very able articles upon this question; I am glad I have so excellent an advocate in you. If you can possibly induce the St. Andrew's Committee to take action in the way I suggest, and that action should happily be crowned with success, what a jolly meeting our next annual meeting will be in Edinburgh! I should then have a double object in going to Scotland—the M.D. at St. Andrew's, and the jollification at Edinburgh.

Yours, etc., C. C.

PSYCHOLOGIST (Birmingham).—At the dissolution of Parliament on May 7th, 1737, His Majesty gave his Royal assent to the several acts of the past session, among others one "to enable Lunatics and Idiots to make Conveyances, etc." See the *Gentleman's Magazine*, vol. 1, p. 212.

Q. E. D.—It will be necessary to pass an examination in Greek, in French, or German, and in Algebra (unless the certificate already possessed show that this last subject was included in the preliminary examination for the Membership). An examination must also be passed in one of four optional subjects, which may be Chemistry.

THE CROONIAN LECTURES ON ADDISON'S DISEASE.

Delivered at the Royal College of Physicians, London.

By E. HEADLAM GREENHOW, M.D., F.R.C.P., F.R.S.,
Physician to and Lecturer on Medicine at the Middlesex Hospital.

LECTURE II.

I SAID in my last lecture that Addison's discovery has not yet been generally accepted, nor even generally understood. The connection of the constitutional symptoms and bronzing of skin with the disease in the suprarenal capsules, is still regarded by many rather as a matter *sub judice*, than as a certain and definite relation. This scepticism is no doubt partly due to the fact that the relation between the disease of the suprarenal capsules and the clinical symptoms associated with it, is much less susceptible of obvious explanation than the relation between the organic lesion and the clinical symptoms in many other diseases. To this part of the question I shall refer in my next lecture; but, in the meanwhile, it is evident that the obscurity of the relation can be no bar to the recognition of its reality, if this latter be substantiated by a sufficient number of well attested facts.

The general acceptance of Addison's discovery has, however, been mainly retarded by the prevalence of misconceptions which have prevented its being generally understood. I propose, therefore, to review in the first place the evidence proving the reality of the relation, and subsequently to deal with the misconceptions which have interfered with its general recognition.

If it were only that so obscure a disease, as one particular lesion of the suprarenal capsules, has been often correctly and publicly diagnosed from the symptoms supposed to be connected with it, it seems difficult to understand that the connection should not be universally allowed to have passed out of the region of theory into that of established truth. I have myself, on twelve occasions, diagnosed Addison's disease of the suprarenal capsules in the presence of medical students and friends, and in eight of these cases the correctness of the diagnosis has been verified at the necropsy. Two of the twelve patients died at a distance from London, and the remaining two are still living. There have now, indeed, been so large a number of cases similarly diagnosed, that it is impossible to enumerate them; and the evidence they afford of the reality of the connection between the clinical symptoms and the pathological condition, would alone seem to me to be unanswerable.

It is still argued, however, in some quarters, both at home and abroad, that, although a diseased condition of the suprarenal capsules may frequently coincide with certain clinical symptoms, it is by no means essential to their development, and consequently cannot be their cause. I shall therefore proceed to show that the whole weight of the evidence furnished by the large number of cases published since Addison's time, as bearing upon the subject of the disease he discovered, goes to prove that the coexistence of the clinical symptoms of Addison's disease with one particular lesion of the suprarenal capsules, is the almost invariable rule; the exceptions to which, if duly investigated, may be satisfactorily explained. I shall also be able to show that this particular lesion is essential to the development of those symptoms, in so far that medical records have as yet produced no single case exhibiting the really characteristic features of Addison's disease, in which this particular lesion of the suprarenal capsules was not also present.

For many years past I have from time to time collected all the cases I could find in the *Transactions* of medical societies, or in the British or foreign medical journals, published under the name of Addison's disease, Bronzed skin disease, disease of the suprarenal capsules with or without bronzing, and bronzing of skin with or without disease of the suprarenal capsules. I cannot suppose, however, that none have escaped me, for I have not had access to all the medical works in which cases may have been recorded, and latterly my leisure for such researches has been less than in former years. This collection now amounts to 332 cases, in all of which there is a more or less complete report of the morbid appearances found after death; for I have disregarded, as useless for my present purpose, all those cases which have not undergone the test of *post mortem* examination.

Of these 332 cases, a very considerable number fall into three classes, which must be set aside till the latter part of this lecture. One of these classes includes all the cases in which no disease at all of the suprarenal capsules was found; the second, all those

cases in which the disease found in the suprarenal capsules was altogether of a different nature from the particular lesion characteristic of Addison's disease; whilst in the third class are comprised all those cases in which the description of the condition of the suprarenal capsules leaves doubtful the nature of the lesion, and in some instances the existence of any lesion at all. After deducting the cases which fall under these three classes from the total number collected, there remain 228 cases, in all of which the suprarenal capsules are reported to have undergone the one particular morbid change which I described in my last lecture.

As regards the reality of the relation between this particular lesion of the suprarenal capsules and the clinical symptoms supposed to be associated with it, I take first, because most indisputable, the evidence furnished by 101 of these cases, which may be classed in one group as typical cases of Addison's disease—typical as corresponding in all their main facts with the outline of Addison's own description—more or less typical, according as the length of their course or as opportunities of observation have enabled their reporters to present more or less in detail the remarkable features which fill in that outline. In all these 101 cases, the train of constitutional symptoms and the peculiar change of colour in the skin were observed, during life, more or less fully developed. In all the 101 cases, the suprarenal capsules were found after death to be diseased, and the disease was in every case of the same nature, corresponding with one or other of the stages of the particular lesion which I have described. And, lastly, in none of the 101 cases was there any other organic lesion existing which could be of the slightest importance. There can surely be no reasonable doubt that, in every one of these cases, the disease of the suprarenal capsules was, either immediately, or mediately through its consequences, the sole cause of death.

But although, with the view of alluding first the most unanswerable argument to be derived from the fact collected, I have placed in a group these 101 cases which I have called typical by themselves, there is another large class which, in reality, affords scarcely less convincing proof of the connection between the clinical symptoms and the suprarenal disease. In 51 more cases, both the constitutional symptoms and the discoloration of the skin were observed during life in a more or less typical form, but either the other organs were not examined so as to place beyond question the absence of any existing disease; or else some complicating disease actually existed, giving rise to its own symptoms independently of those characteristic of the suprarenal lesion. A large proportion of these cases, however, are, in fact, as typical examples of the disease as any of those I have placed in the previous group. Again, in 31 other cases, some of the characteristic constitutional symptoms are reported, together with some discoloration of skin, but in some of these cases the descriptions are too meagre to justify my placing them in the first or second group; whilst in others there was coexisting disease serious enough to modify or obscure the symptoms of suprarenal disease.

We have thus, out of the 228 cases in which the one particular lesion of the suprarenal capsules has been found, no fewer than 183 cases in which the peculiar change of colour in the skin, and some at least of the characteristic constitutional symptoms, were observed during life.

In 16 of the remaining 45 cases, the clinical history and symptoms are either altogether wanting, or are too imperfectly recorded to warrant any conclusions being founded upon them. Amongst this number are included several cases which occurred before the announcement of Addison's discovery. These 16 cases being necessarily left out of the question, there remain only 29 of the 228 cases still to be accounted for; and in these 29 cases it is distinctly stated either that no functioning of the skin existed, or that it was almost inappreciable.

In 18 of these 29 cases, the disease of the suprarenal capsules co-existed with advanced phthisis or vertebral disease, with tuberculosis, ascites, or Bright's disease. In two or three of them, the coexisting disease was acute tuberculosis, which always runs a very rapid course; and in most of the others the coexisting diseases were attended by a considerable and exhausting drain, such as profuse suppuration from abscesses in vertebral disease, or from the lungs in phthisis, and loss of albumen from the blood in Bright's disease. Three of these cases occurred in the Middlesex Hospital, and I was present at the *post mortem* examination of one of them, and verified the absence of all trace of discoloration of the skin; but the patient, a boy aged 13, had been rapidly worn down by profuse discharge of pus from an abscess connected with carious vertebrae. A few of these cases have presented, however, some of the peculiar constitutional symptoms due to the suprarenal lesion, in addition to those of the more obvious disease, though not of sufficiently marked form to give rise to any suspicion of their real cause until it was discovered at the necropsy. Thus, in the second of the three Middlesex Hospital cases to which I have referred, Dr. Thomp-

son recorded in the case-book that the patient, a man aged 40, who died after an illness of only six weeks, with extreme disorganisation of the lungs, had, before he took the cold which brought on his rapidly fatal illness, been suffering from languor, failure of appetite, and vomiting after food. The third case, one of vertebral disease and incipient phthisis, was under the care of Mr. Hulke, who stated that the patient suffered from a degree of feebleness quite out of proportion to the loss of flesh, a very irritable stomach and obstinate constipation. In this last case, it was obvious that the suprarenal lesion was in a comparatively early stage when the patient died, for the inflammatory exudation with which the right capsule was infiltrated had not undergone the process of caseous degeneration, and the left capsule appeared still healthy.

The inference which I draw from the absence of the bronzing of skin, and mostly, also, of the constitutional symptoms in these eighteen cases, is that, in most of them, the diseases co-existing with the disease of the suprarenal capsules proved fatal before this latter had produced its characteristic effects; whilst in others, the end was probably hastened by the debility and depression which are usually the first symptoms of the suprarenal lesion, but which, in such circumstances, would naturally pass unnoticed. As we have seen, Dr. Thompson's and Mr. Hulke's patients did both present such symptoms, distinct from those of the more acute diseases which caused death—a fact which seems to confirm the inference I have drawn with respect to these cases.

The explanation of the other eleven cases in which it was stated that there was no bronzing of the skin, is at first sight less obvious. In none of these cases was there any co-existing disease of importance, and some of them are amongst the most typical on record as regards the constitutional symptoms. Nearly all of them, however, have been cases in which the illness has been of comparatively short duration, only two having exceeded a course of four months; in several there must have been, notwithstanding the absence of any developed bronzing, some peculiarity in the colour of the skin sufficient to attract attention, as slight duskiess, unnatural darkening of skin, peculiar sallow hue, and so on, are noted, together with the absence of bronzing. In one case, however, fully reported by Hertz in *Virchow's Archiv* for 1870, there was no trace of discoloration of the skin even at death; but the illness appears to have been of short duration; for, although the patient reported himself to have been failing in health since an attack of cold and ague a few months previously, he only presented himself at the hospital a few days before his death. At that time, he had still some appetite, and the description of his condition is not that of an advanced stage of the disease; but he sank suddenly with severe nervous symptoms. In another case, under Dr. Owen Rees, reported by Dr. Wilks, which was most characteristic as regards the constitutional symptoms, and in which the patient was failing in health a year and nine months, there was no discoloration. The same may be said of two other cases recorded by Dr. Bristowe and Mr. Crossman, lasting four and eight months respectively. This last case of Mr. Crossman's is the longest on record, in which death has taken place with all the characteristic constitutional symptoms of Addison's disease without any bronzing of the skin. There is, however, one case included in the eleven, in which the illness is said by Mr. Bruce, who reported the case for Dr. Russell Reynolds, to have lasted eighteen months. But, as the patient had been always delicate and a hard drinker, and as the only symptoms observed were sickness, loss of flesh, and a sense of emptiness at the epigastrium, it may have been difficult to fix the commencement of the illness due to the disease of the suprarenal capsules. It is certain that this latter was not in an advanced stage at the time of the patient's sudden death, for a little of the proper tissue of the organs was still found remaining.

The simple and satisfactory explanation of all these cases lies, I believe, in the variable comparative date of the development of the constitutional symptoms and of bronzing of skin in different cases, to which I drew attention in my first lecture as one of the peculiar features in the course of this remarkable disease. It was at first thought that absence of bronzing of skin, in otherwise obviously characteristic cases of Addison's disease, might be accounted for on the supposition that a course of several months at least was requisite for the development of the bronzing. More extended clinical observation has now established the fact that, in a certain number of cases, the bronzing of skin is more or less developed for considerable periods of time before the patient feels any symptoms of illness; whilst, on the other hand, in a considerable number of cases, the constitutional symptoms have shown themselves for a longer or shorter period before the appearance of any discoloration of the skin. It is evident, however, that cases belonging to the former of these classes are far less liable to give rise to misunderstanding than cases of the latter class; for, whilst those patients who are affected first by the discoloration of skin will live on as usual

until the constitutional symptoms make their appearance, those patients in whom the constitutional symptoms are first developed may very possibly die, especially if exposed to any external depressing influence, before the appearance of the discoloration of skin. This is, in fact, precisely what I believe to have occurred in all the eleven cases I am now discussing. I believe them to have been all typical cases of Addison's disease, whose course was cut short by individual feebleness or by unfavourable circumstances before the development of the bronzing of skin, which would presently have taken place, as in the cases quoted in my previous lecture, if their course had been sufficiently prolonged.

Looking at all the difficulties which have stood in the way of our obtaining full and accurate reports of even the recognised cases of this rare and obscure disease, and to the certainty that many cases have remained unrecognised until after death, when it was too late to fill up deficiencies in the clinical records, I cannot but regard these statistics as furnishing conclusive evidence of the constant relation of a certain train of constitutional symptoms and a peculiar change of colour in the skin due to one particular diseased condition of the suprarenal capsules.

Such a weight of concurrent testimony to the truth of Addison's discovery would scarcely have remained so long without effect, had it not been for the extensive prevalence of those misconceptions to which I have alluded, as obscuring the true aspect of the question from the moment when it was first submitted to the profession. These misconceptions had reference chiefly to the characters of the discoloration of skin and of the lesions in the suprarenal capsules; and they originated, as we have seen, in a great degree in Addison's own mistakes. He subjoined to his own typical cases others presenting discoloration of the skin and disease of the suprarenal capsules of quite different characters, and unassociated with any of the apparently causeless constitutional symptoms which had attracted his attention. He also gave the disease the name of *Melasma suprarenale*, for which afterwards was substituted that of "Bronzed skin disease," thus identifying the disease itself with its most conspicuous, but least important, feature. Thus, the asthenia and the other peculiar constitutional symptoms, which at first revealed to Addison the existence of the disease, were in a great measure overlooked, both in reports of cases and in discussions based upon them. Numerous cases were brought forward, on the one hand, only to show that discoloration of the skin not unfrequently occurred without any disease being found in the suprarenal capsules; and, on the other hand, only to prove that discoloration of the skin did not always result from disease of the suprarenal capsules, even when sufficiently extensive to cause the entire destruction of those organs.

In both these classes of cases, the facts were undeniable, and the inferences drawn from them have constantly been alleged as the principal arguments against the truth of Addison's discovery—namely, that "discoloration of the skin not unfrequently exists without any disease of the suprarenal capsules," and that "disease of the suprarenal capsules not unfrequently exists without producing any discoloration of the skin." Both these allegations are undoubtedly true; but, as I shall proceed to explain, neither of them contravenes, in the slightest degree, the reality of the relation which subsists between the peculiar change of colour in the skin and the particular lesion of the suprarenal capsules which are found in Addison's disease.

First, then, discoloration of the skin does frequently exist without any disease of the suprarenal capsules, but it is discoloration which either presents altogether different characters from that associated with suprarenal disease, or which, if more or less resembling it, is easily referable to some other obvious pathological cause or to some known physiological condition. Neither Addison himself, nor any one who upheld his views, has ever maintained that disease of the suprarenal capsules was to be regarded as the only cause of discoloration of the skin. This would have been as absurd as to assert that disease of the kidneys was the only cause of dropsy. In both cases, the truth discovered was the relation between a hitherto undiagnosed local lesion and one particular form of an obvious affection.

There are various conditions, both physiological and pathological, which are frequently accompanied by general or partial darkening of the skin; but, as the former are universally known and attributed to their true physiological causes, I need not dwell upon them, and therefore pass on to the various discolorations of the skin produced by pathological causes which have more or less frequently been confounded with the peculiar discoloration of Addison's disease. Amongst these there is, perhaps, none more striking than the cutaneous discoloration often seen in elderly persons of very indigent circumstances and of uncleanly habits, especially when infested with vermin. I have the records of several such cases which have been under my own care in the Middlesex Hospital, either for obvious disease, or simply for the debility and sinking consequent on long continued hardships and exposure. In

the year 1864, I exhibited one of these cases at the Pathological Society, as a case of bronzed skin disease simulating the discoloration of Addison's disease. Such cases, however, though they undoubtedly present some appearances of Addison's disease, may be easily distinguished from it. In my patient, a woman, aged 65, the skin was extensively bronzed, especially over the abdomen, chest, and back; but the discoloration, when carefully examined, was totally different from the bronzing of Addison's disease. It was seated in the superficial instead of in the deeper layers of the epidermis. It was paler instead of deeper in the face, hands, and other parts, which are naturally the seats of most pigment. These small, isolated, dark spots were all on the pale instead of on the discolored parts of the skin. Moreover, the darkened cuticle was not soft and smooth, but in many parts raised and rough. Such constitutional symptoms as were present—debility, languor, and a sense of sinking at the epigastrium—were referable to apparent causes, and were soon removed by tonic treatment, and an ample supply of food. I should add that, by the use of alkaline warm baths and soap, the discoloration was greatly diminished, though the skin did not regain its normal hue.

Again, it is well known that pityriasis versicolor is attended by discolorations of the skin, and cases of this kind have been adduced to disprove the connection between bronzed skin and disease of the suprarenal capsules; but the nature and the distribution of these discolorations, as well as their modes of development and disappearance, are widely different from the two characters of the discoloration of skin in Addison's disease. The dark patches are more upon the trunk and limbs than upon the face. They have abrupt margins and convex borders, and are interspersed with spaces of normal coloured skin; they appear and disappear rapidly: and no asthenia or other constitutional symptoms are associated with them.

Syphilitic eruptions, also, notoriously cause more or less permanent stains on the skin; but, although their coppery hue and spotty character distinguish them clearly enough from the bronzing of Addison's disease, they are sometimes confounded with it, for two such cases have been sent to me in private practice, on the supposition that they were cases of Addison's disease.

There are, however, various kinds of discoloration of the skin which bear a somewhat more real resemblance to the bronzing of Addison's disease, in so far that the skin remains soft and smooth, and the pigment is deposited in the same layers of the epidermis, though not in the same quantity, nor usually to the same extent, nor in the same characteristic seats. Such discolorations are well known to be produced occasionally by diseases peculiar to women, by tropical and malarious fevers, by hepatic disease, and by very chronic phthisis. Of this last class of cases I have seen several remarkable examples since my attention has been directed to the subject. A woman, aged 26, who died under my care in the Middlesex Hospital of chronic phthisis in 1871, presented precisely the appearance of Addison's disease in an early stage, the face having the same peculiar duskiess, and the forehead, except where covered by the hair, being of a distinct brown colour; the skin was soft and smooth. Another phthisical patient, a man, aged 50, was sent to me in 1872 by my colleague Mr. Nixon, with abnormal pigmentation of the tongue, exactly resembling that seen in Addison's disease. My colleague Dr. Thompson asked me some time ago to examine a man, aged 55, who was suffering from bronchitis and emphysema, and, it was suspected, long-standing phthisis. He exhibited several brown patches, corresponding to the extent of superficial injuries received from a fall about a year before; and on the lower part of the sternum was a transverse irregular white cicatrix an inch and a half long and a quarter of an inch wide, encircled by a dark brown ring nearly half an inch in width, fading off into the normal hue. The skin of the groins was also slightly dusky. These partial discolorations strikingly resembled those found in similar situations in Addison's disease, but they neither deepened, nor spread over the general surface during the subsequent illness of the patients, nor did these latter show any symptoms but those of pulmonary disease. In all these cases, the suprarenal capsules proved to be perfectly healthy. The observation of these and similar cases has convinced me, that no partial discolorations of skin are to be relied on as diagnostic of Addison's disease, unless found in conjunction with the characteristic constitutional symptoms.

ROYAL COLLEGE OF SURGEONS.—Mr. John Hilton, F.R.S., who was elected a member of the Court of Examiners of the Royal College of Surgeons in 1865, has resigned his appointment which he has so long and so honourably filled. The Council, of which he was elected a member in 1854, will still retain the benefit of his experience. A special meeting of the Council will be held on Wednesday next, the 17th instant, for the election of a Fellow of the College, to fill his vacant chair.

THE GOULSTONIAN LECTURES ON PUERPERAL FEVER.

Delivered at the Royal College of Physicians, London.

BY ROBERT J. LEE, M.D., F.R.C.P.,

Assistant Physician at the Hospital for Sick Children, Great Ormond Street.

LECTURE III.

THE only point on which I now feel some hesitation is, whether this explanation of the origin of puerperal fever, and its contagious nature, is so generally admitted as to allow us to proceed in our inquiry without interruption by objections to it. Our students are generally told in the text-books that puerperal fever is "a continued fever communicable by contagion, occurring in connection with childbirth, and often associated with extensive local lesions, especially of the uterine system". (Aitken.)

There is no doubt that a considerable number of experienced practitioners believe in epidemic influences, and are quite ready to allow that there is strong evidence to make them conceive that in certain cases the fever has been communicated from one person to another. It is only a short time since that one of our leading journals, in remarking on a case of manslaughter which has excited attention very properly on the question of contagion, observed: "Is it certain that puerperal fever is contagious?" It seems to me a very important matter indeed that there should be no mistake on this question, at least as a practical one; for, whether we believe or disbelieve the theory of contagion, we must regulate our practice by the opinions of those of the greatest experience and knowledge.

Supposing even that we cannot demonstrate the perfect truth of the theory, and that we cannot explain certain apparent exceptions to it, it is necessary to remember that it is sufficient, if the proof can be carried so far as to obtain consent to the probability of the theory being true. In this case, "probability is the very guide of life"; and the rules laid down by an able writer, on the extent to which we ought to be satisfied with the evidence of such probability, are so much to the purpose, that I shall take advantage of them to express the opinion, which I think we shall agree in supporting, in respect of this matter.

"From these things, it follows", says that able logician Bishop Butler, "in questions of difficulty, or such as are thought so, where more satisfactory evidence cannot be had, or is not seen, if the result of examination be, that there appears, upon the whole, the lowest presumption on one side, though in the lowest degree greater, this determines the question even in matters of speculation, and, in matters of practice, will lay us under an absolute and formal obligation, in point of prudence and of interest, to act upon that presumption or low probability, though it be so low as to leave the mind in very great doubt which is the truth. For surely a man is as really bound in prudence to do what, upon the whole, appears according to the best of his judgment to be for his happiness as what he certainly knows to be so." (Butler, Introduction to *Anal. Relig.*) It is quite easy to perceive what a great difference must exist between the views entertained by one who believes thoroughly in the contagious theory and those of one who does not believe in or is doubtful of it. By the former, epidemics of the fever are not admitted; symptoms are all referred to the influence of a poison circulating in the system, which accumulates in tissues and produces general disturbance as well as local pathological changes. Variations in the pulse and temperature are explained by the same cause, and the remedies which appear most rational depend upon the principle of opposing the poisonous influence, while the fear of conveying septic matter from one case to another will always suggest precautions which would be disregarded by one who doubted such a possibility. In regard to the question of lying-in institutions, and in his views of the dangerous proximity of the *post mortem* room, he would hold only one opinion. In many other ways which need not be mentioned, his professional conduct would be regulated in regard to various cases which might occur in his practice of those diseases which are also the source of the infecting poison. If he engage in discussion on these practical questions, he carefully declines to argue on the meaning of the term contagion. If it be stated that puerperal fever, in a large number of instances, cannot be traced to any source of infection, he replies that his theory does not involve such a necessity; that the symptoms may arise from the decomposition of organic matter in the patients

own person; and he does not allow the limited meaning of the term contagion as used in such diseases as scarlatina, variola, and others, to be adapted in the case of puerperal fever; and, so far as such diseases occurring in the puerperal state are more serious than under other circumstances, he would either assert that he doubted the fact, or that, if it be occasionally true, he would still adhere to the opinion, that such increase in the severity of symptoms might be explained upon the principle of septic infection.

There may undoubtedly be some demand upon the imagination for those who find it difficult to conceive of invisible and subtle agents of whose existence there is only the evidence of effects; but, when the mind is educated by acquaintance with many natural phenomena that can only depend on un-seen forces or energies, that difficulty diminishes, and a consideration of the extraordinary character of the effects produced by the action of all poisons on the human system will assist in allowing the same method of reasoning to be employed which is pursued in the investigation of the laws which regulate the action of chemical, physical, and other forces. That those who are engaged in other departments of scientific investigation are required to exercise the imagination, when they have arrived at the limits of actual perception, is proved sufficiently by the following remarks of one of the leaders of experimental research in the domain of natural philosophy.

Fig. 1.—Section of Pleural Membrane, with network of Lymph-vessels full of Bacteria. Natural size (Heiberg).

"I would simply draw attention", says Professor Tyndall, "to the fact, that in the atmosphere we have particles which defy both the microscope and the balance, which do not darken the air, and which exist nevertheless in multitudes sufficient to reduce to insignificance the Israelitish hyperbole regarding the sands upon the sea-shore." "It cannot be too distinctly borne in mind that, between the microscope limit and the true molecular limits, there is room for infinite permutations and combinations." (*Microscopical Journal*, vol. x, p. 416, new series.)

Fig. 2.—Section through a Bacterian Embolus in a minute Artery in the Kidney. The patient sank very rapidly after delivery, and the post-mortem examination led to an explanation of the symptoms in the gangrenous condition of the placental surface, and venous thrombosis in the tissues which correspond to that part. In the lungs and heart, abscesses containing bacteria were found (Heiberg).

It is quite clear that, if the efforts be successful which are now being made to demonstrate the actual existence of organic poisons developed in the process of decomposition, we shall some day be enabled to

account satisfactorily for the different symptoms which they give rise to when introduced into the human system, and for the pathological changes they produce in the different tissues of the body.

This question of the different characters of the products of decomposition is, of course, extremely difficult to decide. We have only to be careful to require that observations should be accurate, and that theories should not be hastily proposed. It might appear quite an easy matter to investigate the results of the decomposition of any particular organic substance, and determine the sensible properties of the minute organisms which are developed in that process; I say it might seem easy to do this; but practical observation soon dispels this idea. The field of the microscope is seen to be crowded with particles of extreme minuteness, of variety of form, reflecting and refracting light in various degrees, and exhibiting movements of more or less complexity. Those movements may be independent of the organisms themselves; that is to say, they may be produced by external forces. Thus, if we employ only our powers of vision, though we may magnify to any extent, as a means to discover their characters, and to distinguish them from one another, we are only using morphological principles as the basis of classification.

This limitation of their powers of analysis with the microscope none are so well aware of as the most experienced observers, and there is but little danger of our being led to erroneous conclusions by them. Those who are least experienced in the difficulty of microscopic research are more likely to exceed the limits of observation, and to indulge in theories which will prove eventually to be only partly true.

It would be difficult to do justice in these lectures to the researches which have lately been made into the interesting and important subject of decomposition. A learned Fellow of this College has fairly stated the general results of the most recent investigations of Continental observers, after verifying them by independent examination, as well as contributing some information of value himself in his recent lectures at Owens College, Manchester (*vide BRITISH MEDICAL JOURNAL*, January 26th, on the "Occurrence of Organic Forms in connection with Contagious and Infectious Diseases"); and his conclusions are more in accordance with all that we know from experience, clinical observation, and experiments, than could be expected from one who, like the distinguished Professor at Jena, has made the study of the different species of organisms, and their development, almost his sole object of inquiry.

Fig. 3.—Canals in the Pyramidal Portion of the Kidney full of Bacteria. Between the canals, the stroma of the kidney contains some fat-globules. The specimen was taken from a patient who died about four weeks after delivery from puerperal infection. Numerous abscesses with which lymphatics communicated were found in the peritoneal tissues. Both kidneys were large, pale, and soft, and contained streaks and spots of yellowish colour, and numerous points of ecchymosis. The liver was slightly enlarged, of paler colour than normal, and the divisions of the acini were indistinctly defined. The pericardium was spotted with points of ecchymosis, and its serous cavity contained sanguous fluid (Heiberg).

It is only necessary to select such of these observations as bear directly on the symptoms and pathology of their subject. Those who are unacquainted with the general characters of the minute organisms which are classed under the term bacteria may readily obtain some idea of their dimensions, forms, and other distinguishing features, by the examination of any fluid containing decomposing organic matter. For instance, the secretion in carcinoma uteri may be subjected to microscopical examination with the quarter-inch or half-inch object-glass; and, instead of a simple collection of bacteria, in decomposing we have the cells of tissues with which we are tolerably familiar, to assist us in forming some idea of the extreme minuteness of those organisms. A cancer-cell appears to be capable of containing quite a considerable number of the darkish globular granules, which are now looked upon as special forms possessing active infective pro-

perties. We can readily recognise in such a preparation the staff-shaped bacteria, properly so-called, with their undulating mode of progression, the spirilla with rapid axial rotation, the more obscure movements of the vibrios, and, lastly, the comparatively insignificant globular micrococci. It is the last of these which, under special names, as micrococcus diphtheriticus, micrococcus vaccinia, and others, which are not so easy to distinguish from one another as to make us quite satisfied of their specific character, that are now engaging the attention of pathologists in relation to the various changes of tissue which are met with in puerperal disease.

There is no difficulty whatever in conceiving it quite possible for even the larger bacteria to traverse the smallest capillaries: for we have only to introduce under the cover of the microscopic slide a few red blood-corpuscles, in order to perceive that three or four staff-shaped bacteria placed side by side could follow a blood-cell in its passage through minute vessels. And, when we observe that a micrococcus is a sphere whose diameter is not equal to that of the staff-shaped bodies, we can imagine it capable of exerting local morbid influence by interruption of the physiological processes, which are constantly taking place in the body.

My object in presenting in this familiar manner the general characters of bacteria is rather to favour the view that, instead of treating them with contempt, we may not only appreciate the fact of such organisms existing, but may give some scope to the imagination when we are considering the question of morbid poisons, and are asked to believe in much that cannot be brought within the range of actual perception. It might be reasonably objected that there is great liability to error in microscopic analysis of the characters of micrococci, and that we might easily mistake other cellular forms for them. This is an objection which is perfectly true, and against which the microscopist has to guard very carefully.

At present, there seems to be one test which may be applied in pathological examination of tissues supposed to contain micrococci, and this is required by the fact, that the minute globules of oil commonly met with in all tissues in certain pathological conditions resemble micrococci so closely as to make it difficult to distinguish between them. This has suggested the immersion of such tissues in strong solution of caustic potash, which is known to have no effect upon the microscopical appearance of a micrococcus.

By these means, Professor Heiberg of Christiania (*Die Puerperalen und Pyämischen Processen*, Leipzig, 1873) has lately succeeded in satisfying those who have had an opportunity of examining his preparations, and who are qualified to form an opinion upon their value, that, in cases of puerperal fever, very many tissues may contain bacteria. He has exhibited specimens in which the lymph-canals of the serous membrane of the liver are seen to contain them in small groups or "colonies"; and they are not confined to the canals, but seem to have permeated their walls and invaded the external tissue. Similar groups are found in the lymph-vessels of the pleural membrane; in the tissue of the cardiac valves, which is rendered slightly opaque and swollen around them; in the arteries and tubes of the kidney; and, among other results of investigations, Professor Heiberg describes them in those lacunae which exist in the nasal mucous membrane, and communicate by fissures with the surface.

We can easily apply these facts to the explanation of the formation of minute abscesses around arterial emboli, and to the different pathological conditions which follow a simple fibrinous coagulum arrested in the circulation, as compared with one containing active micrococci. This is the direction in which pathological investigations will be made by those who support these views of the connection between bacteria and puerperal fever.

The idea of searching for micrococci as Professor Heiberg did was suggested by reflection on the difference between one embolus and another, that is, from a comparison between the state of the tissue surrounding small collections of healthy pus, which had been injected into the veins, and had been arrested in the minute branches of the pulmonary artery, and the much more active changes which resulted from the injection of material containing bacteria.

It was in a case of ulcerative endocarditis occurring in pyæmia that Professor Winge first referred to the existence of micrococci in the pathological changes observed in the endocardial membrane, Professor Virchow having previously described this particular form of ulceration in puerperal fever as of diphtheritic nature. This case of Winge's was followed by another, the details of which were supplied by Professor Heiberg, and was accompanied by a postscript by Virchow, in which he refers the species of micrococcus to the genus *Leptothrix* of Hallier, expressing the necessity of caution in deciding upon this difficult point, as the very minute size of the corpuscula, and the absence of movement in the particles, necessarily make the microscopical examination some-

what uncertain. However, he states very positively that they are parasites, and are related to diphtheria and blood-infection. This is the present state of our knowledge regarding bacteria in their relation to puerperal infection; and, as there seems to be good reason for believing in the facts as far as they go, we might decline to speculate upon the question which presents itself, Whether these micrococci are active agents themselves in producing the effects described, or whether they are only the vehicles of a subtle poison which attaches itself to them as well as to any other particles of matter, whether micrococci or not. Or suppose that we question the specific characters of the micrococcus, and ask whether there may not be others of equally active properties whose presence we cannot detect in the fluids or tissues. When we know how many varieties of bacteria are developed in the process of decomposition, we should feel inclined to doubt whether one and all might not be equally capable of producing poisonous effects when introduced into the system.

ABSTRACT OF THE LUMLEIAN LECTURES

ON

LIFE, AND ON VITAL ACTION IN HEALTH AND DISEASE.

Delivered at the Royal College of Physicians, London.

By LIONEL S. BEALE, M.B., F.R.S.,
Physician to King's College Hospital.

LECTURE I.

[DR. BEALE began his lecture by referring to the controversies which have taken place as to the nature of life, and commenting on the manner in which they have been carried on. He then proceeded to express the grounds of his dissent from the physical doctrine of life.]

To the doctrines now generally taught and fast becoming very widely diffused, I am and have been strongly opposed. In certain particulars, those doctrines are in conflict with views based upon well observed facts, in relation to the growth and multiplication of every known form of living matter, and the formation of the tissues of living beings. Many observations, though repeated again and again, must be entirely erroneous if the positive statements recently made concerning the phenomena of living beings be true. It may be presumptuous, perhaps, to suggest that the conclusions arrived at by me many years ago, ought not to have been wholly ignored by authorities who have expressed themselves in very confident language concerning the physical nature of life; but people have been informed again and again that all the phenomena of living beings are due to physical changes, although it has been pointed out that phenomena, characteristic of every kind of living matter, cannot be so explained. I have for many years pleaded in vain that, for example, an attempt should be made to explain the movements of an amoeba, or a mucus-corpuscle, by physico-chemical action.

It is right, as it seems to me, now to proceed a step further, and challenge the supporters of the physical theory of life to publicly reply to the objections urged against the statements they have made. For has not the time arrived when the facts and arguments upon both sides might be summed up and judgment given, whether the physical doctrine of life is justified by the scientific knowledge of the time in which we live; or whether, on the other hand, it is not a thoroughly unscientific inference, based only upon the facts of the imagination, and opposed to facts of observation?

In the physical domain, consequence follows its antecedent with unerring certainty. What will happen under certain given circumstances can be stated with exactness and promised beforehand. But it is not so with the living world. It has yet to be proved that every change there is a direct consequence of antecedent physical change. We cannot predicate of vital as we can of physical phenomena. We have not the certainty of physical law. Nevertheless, with amazing confidence, not, however, resulting from knowledge, some declare that the difference is to be easily accounted for by the greater complexity of the circumstances and conditions which obtain, as regards vital phenomena. When, it is affirmed, by further investigation, these circumstances shall have been fully investigated, man, we are assured, will be able to define, with absolute certainty and unerring precision, the particular living form which shall result from the development, under certain given conditions, of a particle of colourless transparent matter which

represents the earliest stage of being of countless numbers of very different creatures. And yet changes, characteristic of every form of living matter, have been scarcely alluded to by the upholders of this notion. It must, indeed, have struck many as a remarkable fact, that so little has lately been said concerning the relation of life to matter. The connection between mind and body, mind and brain, mind and matter, has been very fully discussed, but the question of the connection between life and body has received far less attention, although the determination of the last is the preliminary inquiry which would naturally be presented for solution, before the nature and relations of mind were touched upon.

Surely we, who have been studying life in many forms, and under varying conditions, ought to urge those who have assumed the responsibility of teaching physical doctrines of life to publicly reveal the facts, and clearly state the arguments upon which they rely for the establishment of the doctrines they assert to be true—doctrines which seem to be based upon mere discoveries of the imagination, though they are, it is to be regretted, believed and taught in the most ancient of our seats of learning, where, strange to say, Socratic philosophy and caution are still inculcated.

Among the doctrines referred to are the following:—The sun forms living beings. The brain and all organs have been built by the sun. All the actions of all things living are mechanical. All things living are machines. Living organisms, as well as crystals, are the products of molecular forces. The mind, the intellect, the will, thoughts and emotions, as well as the body, were once latent in a fiery cloud. The present world and all its inhabitants, past and present, as well as those to come, lay potentially in the matter which was once cosmic dust. The lowest forms of living approximate very closely to non-living material. Only matter and material forces—only atoms and atomic forces have been and are concerned in the formation of all things, living as well as non-living.

Up to this time, no one has succeeded in showing that the above propositions contain the vestige of a substratum of truth, and it would have been easy to have added several others to the above list, of which the same remark would be correct.

In the course of six lectures which I delivered to the College in the spring of 1861, and which were published soon afterwards, and in the course of the same year translated into German by my friend Professor Victor Carus of Leipzig, I directed attention to the remarkable characters of living matter, and pointed out how this could be distinguished throughout nature.* I also showed that in nutrition the pabulum always gained access to the living matter, and that by and out of this latter alone tissue was formed, the very matter that was once living becoming converted into the tissue. Specimens of the living matter were exhibited, some of which were taken from the lowest organisms, and others from the tissues of the higher vegetables and animals, and from man. The varying proportion of living matter in corresponding tissues at different ages was also demonstrated in cuticle, cartilage, muscle, nerve, and other tissues. The living matter was called germinal matter, which term has been since replaced by the short and more convenient word *bioplasm*; and the matter formed from it was termed *formed material*, because it was shown that all tissue, "intercellular substance", and matters resulting from changes in the so-called cell, were formed from the *bioplasm* only.

It was also shown that masses of *bioplasm*, after reaching a certain size, usually less than the $\frac{1}{1000}$ th of an inch in diameter, underwent division, and that, as soon as any mass of *bioplasm* attained a certain definite size (which differs in different creatures and textures, but which is constant for the same), it divided, or portions moved away, and at length detached themselves from it. If the *bioplasm* were to continue to grow, the distance to be traversed by the nutrient matter, before the inmost parts were reached, would soon become so great, that these could not be nourished or subjected to the constant action of currents of fluid. Death would begin in the central part of such a mass, and would soon involve particle after particle as its ravages extended outwards, until the whole of the living mass was dead. There are many circumstances connected with the life of a mass of *bioplasm* which render its growth without division and subdivision a most improbable event. With the exception of that fanciful sheet of living matter once supposed to grow in the sea at very great depths—never seen, but received in undoubting faith by the critical Strauss—the so-called *Rathybius*—large masses of living matter exist not.

* As much misconception has arisen as to the exact date of my observations on account of frequent references on the part of authorities to observations of Max. Schultze and Kuhnle, while mine were wholly ignored, it is only right to draw attention to the fact, that Max. Schultze's *Das Protoplasma* was published in 1863, nearly two years after my lectures appeared, while Kuhnle's *Untersuchungen über das Protoplasma* did not appear till 1864.

In man and the higher animals, it is the exception to find a single mass of *bioplasm* which measures as much as the $\frac{1}{1000}$ th of an inch in any direction. It is not wonderful that particles of matter so small, especially as they are also colourless and structureless, should have been for a long time passed over as of little importance, and almost ignored by some anatomists. In many drawings of tissues which contain numerous masses of *bioplasm*, not one is represented, for it was supposed that the tissue was formed independently of such particles. But the evidence in favour of the view that it is from these small masses of living matter that all tissue grows is incontrovertible. Without them, nothing characteristic of a living organism is formed. These, and not the formed tissues, are the seat of nutrition, formation, and differentiation, and in them is the sole source of metabolic power.

In theory, at least as it seems to me, every worker appeals to, and ought to be protected by, scientific public opinion, which, perhaps, hardly as yet existing in England, is slowly, but it is to be hoped surely, developing itself. An observer should endeavour to accurately describe what he has seen; and, having published the results of his inquiries, should announce, in the only way open to him, that such a work has been completed, and can be obtained by those who desire to see it. It will, however, save under very exceptional circumstances, hardly be possible for him to get attention directed to his observations without some sacrifice of independence, to which no real worker will like to submit, although the only alternative may be to be ignored or condemned as one not fitted to survive in the struggle for intellectual existence.

BIOPASM AND FORMED MATERIAL.—The simple living matter of a microscopic fungus, like other forms of *bioplasm*, is clear, colourless, and structureless, soft, and, when growing quickly, almost diffuent. It is enclosed in a capsule of equally colourless formed material, which, however, is firm, and sometimes even hard. It varies in thickness under different circumstances. By pressure, the capsule may be caused to rupture, and the *bioplasm* within may be squeezed out. When this simple organism is nourished, nutrient pabulum, dissolved in water, permeates the capsule of formed material, and comes into contact with the *bioplasm* within. The non-living matter then undergoes changes, in the course of which it acquires the same properties and powers as the *bioplasm*, which already exists, possesses. The thickening of the capsule of formed material is effected by the deposition of new formed material, resulting from changes in the *bioplasm*, upon its inner surface.

If the fungus particle be placed under favourable circumstances, it will grow. The particle which is growing not only increases in dimensions, but manifests a tendency to separate into two or more parts. Sometimes the living matter exhibits little projections or diverticula from its surface, each of which, after a time, becomes detached, and constitutes a separate particle, which may grow and divide like its predecessors. Now, these phenomena which I have in few words imperfectly sketched, I hold to be vital actions, differing absolutely from any actions known to occur in any kind of non-living matter whatever. They cannot be imitated, and no actions known can be fairly said to exhibit any true analogy with them. These vital phenomena do not characterise the formed material, for the production of this corresponds to the death of the *bioplasm*.

BIOPASM OF BACTERIA.—The living matter of the bacterium is probably the lowest, simplest form of *bioplasm* in nature. The entire organism is so minute as to be difficult of investigation. In 1864, I carefully examined bacteria under the one-fiftieth of an inch object-glass, and was able to demonstrate that, like the lower fungi, the bacterium consisted of *bioplasm*, with a layer of formed material upon its surface, as was proved by carefully crushing a very large bacterium while under observation. The membrane was ruptured, and not only was the *bioplasm* seen to escape, but it exhibited vital movements when free from its envelope.

[Dr. Beale then gave a sketch of the characters of bacteria.]

The germs from which the little particles spring are far more minute. They appear as minute specks, the largest of them exhibiting a circular outline, and probably being spherical. The smallest are too minute to be discerned with the highest magnifying powers at our command. If a specimen of fluid, in which these particles are rapidly growing and multiplying, be carefully examined, many new points will be observed to appear from time to time. After watching with great care for a considerable time a given spot, I have assured myself that new particles actually come into existence; and that one does not, after intently watching for a time, and concentrating the attention upon a certain space, merely see one coming into view after another, as star after star.

The material in which the minute germs of bacteria are embedded, and which, at least in part, consists of formed material produced by

the bacteria, is much softer than the matter of which the capsule of fungi consists. I believe that even the most minute bacterium-germ is surrounded by a layer of such soft formed matter, in which very minute particles of bioplasm divide and subdivide before they attain even the $\frac{1}{1000}$ th of an inch in diameter. When, therefore, bacteria in an early stage of development dry, it is not possible to identify them. When moistened, the dry mass swells up, and the bioplasm in the soft mucus-like matter grows, each particle producing a fresh investment of formed material; and then, if the conditions be favourable, the germs either at once divide and subdivide for a time, or grow into perfect bacteria, which move freely and grow and multiply in this more advanced stage of development.

[The lecturer then referred to the apparently universal diffusion of bacterium-germs in health and in disease, and the great power they possess of retaining vitality.]

Germs so minute as those of bacteria are constantly passed over, and, until they have grown somewhat, it is not possible to identify them. This circumstance has led some to suppose that they are really formed anew from non-living matter, or from a substance in a transition state, which is neither living nor dead. But such a view is not supported by facts at present known, nor is there anything to justify any other conclusion than that all matter is either living or not living.

LIVING MATTER STRUCTURELESS.—As far as can be ascertained by examination under an amplifying power of 5,000 diameters, living matter throughout Nature is colourless and *structureless*. Not only does living matter exhibit no indications of structure, but the highest known form of living matter could not be distinguished from the lowest, and the lowest is not more unlike non-living matter than is the highest. One is, in fact, just as near and just as far from inorganic matter as the other. It has been said that certain organisms only differ from a fragment of albumen by their granular character; but the statement is not correct. In the first place, a granular appearance is not characteristic of living matter. If granules be discerned in it, they are not essential, and are at least as likely to be lifeless as they are to be living particles. Secondly, the differences between any fragment of albumen and any living particle are enormous, but of a kind quite distinct from that suggested in the above statement.

If a portion of pure bioplasm be carefully examined with the highest powers at our command, and under the most favourable circumstances as to illumination, it will be found to be entirely devoid of granular character. Clear, transparent, and colourless, there will not be discernible in any part of it the faintest indication of structure. Nay, if motionless, its presence can only be recognised by the fact of it being a very little less perfectly transparent than the fluid which surrounds it, and by its refracting property being slightly different from that of the medium in which it lives.

There are many characters in which the living differs absolutely from any form of non-living matter yet discovered. One broad essential character distinctive of all living particles is a remarkable capacity of movement, which has not been adequately accounted for.

OF VITAL MOVEMENTS.—Every form of living matter exhibits certain movements, the nature of which has not been determined. The remarkable movements of the common amoeba, of the mucus-corpuscle, of the pus-corpuscle, and of the white blood-corpuscle, are familiar examples of vital movements, and can be seen and studied. Every nutritive act, every form of increase and multiplication, each kind of growth, the production of buds or offsets, the development, the formation and increase of every tissue, involve active movement of the particles of which living matter is composed. Vital movements affect every form of living matter from the very lowest, supposed by some to have been formed direct from the non-living, to the very highest which is concerned in the development of man; but in certain instances only can the movement be actually seen to occur under the microscope. By very slight alteration of the conditions existing during life, the movements may be caused to cease; but, in many cases in which no movement has been seen, we have other evidence that it has occurred. Vital movement, there can be no doubt, accompanied the first dawn of life, and will continue to characterise living matter to the end of time. In fact, vital movements are essential; their cessation is coincident with the cessation of life. Without them, life is not conceivable; and it is equally impossible to conceive any form of matter not in a living state which manifests movements like those which characterise life.

I propose to consider the subject under the four following heads; viz.:

1. Vital movement which may affect every part of a mass of living matter.

2. The movement of the constituent particles of a living mass, which takes place in a direction from centre to circumference.

3. Movement of one portion of a mass of living matter from the rest.

4. The movement of a mass of living matter from one place to another.

Lastly, there are certain movements which are indirectly due to the vital movements of bioplasm, such as ciliary action, some movements connected with nerve-actions, the movement of certain solid particles in cells, etc.; but these will not be discussed here. Neither shall I enter into a discussion concerning the nature of "contractility", which has by some been considered to be vital in the same sense as the movements which I am about to describe. I have, however, adduced reasons for holding that contractility, as it occurs in muscle, is essentially distinct from the changes now to be discussed.

1. *Vital Movements which may affect every part of a mass of Living Matter.*—These movements are undulatory, and may be seen in many forms of living matter. The wave-like movement gives rise to continual changes in the thickness of the mass, which, as a whole, may remain quite stationary. If the margin of the mass of living matter be studied, its outline will be observed to continually alter; a slight bulge at one place, a slight depression at another. In a few moments, perhaps, the part which projected will recede, and that which was depressed will become prominent, but with no regularity, with no alternation of movement. Such changes may be seen continually proceeding over every portion of a mass, in some cases occurring very quickly, in others slowly. In the amoeba, these movements are distinct enough. The matter which moves is perfectly transparent and structureless. Granules suspended in it may be moved, but they are not the cause of the movement. Wave-like movements may be seen in young epithelial cells. I have seen them in epithelium from the throat and from the bladder of man, and I think there can be no doubt that they take place in living matter generally. In the white blood-corpuscle they have been studied by many. I conceive that it is by movements of this kind that the little masses of bioplasm near the surface of the brain, which I believe are concerned in mental operations, act upon the delicate nerve-fibres which are in contact with all parts of their surface.

2. *Movements of the Constituent Particles of a Living Mass which take place in a Direction from Centre to Circumference.*—The actual movements referred to under this head cannot be seen, for they take place slowly, and affect particles too small to be seen with the highest powers. But that motion in the direction indicated does occur, seems to me to be conclusively proved by the fact that in some spherical masses of growing bioplasm, which are increasing rapidly, a new centre (nucleus) appears in the very centre of the mass. After this has grown for a time, another new centre (nucleolus) appears in the centre of the first. The new growth originates centrally, and a newer growth still more centrally. This involves a movement of constituent particles outwards. Now, if bioplasts, in which this change is actually proceeding, be coloured with an ammoniacal solution of carmine, which in some instances may be effected in a few seconds, the remarkable fact will be observed that the new centres have been stained most deeply, although these are situated at the greatest distance from the surface in contact with the coloured solution. All "nuclei" and "nucleoli" are new centres of growth, and invariably consist of living matter. An oil-globule may be formed in bioplasm, and may be called a nucleus or a nucleolus, but the formation of such a body is of no importance. It ought never to have received the name of nucleus. The movement outwards of the constituent particles of bioplasm is, I venture to think, the circumstance which determines the flow of the nutrient fluid in the opposite direction.

3. *Movement of one portion of a mass of Living Matter from the rest.*—This form of vital movement can be seen without any difficulty. A bulge appears upon the surface of a mass of bioplasm. This gradually increases and becomes pear-shaped. The projecting portion of the living matter moves away from the general mass with which, however, it may remain connected for some time by a narrow pedicle. Such movement of living matter may be seen in the Amoeba, in the mucus-corpuscle, in pus-corpuscles, and in white blood-corpuscles, and many other forms of bioplasm. What determines the precise spot upon the surface where the formation of the bud or outgrowth commences it is difficult to say.

4. *Movement of a mass of Living Matter from place to place.*—This form of vital movement is also to be seen very distinctly, and so many instances of its occurrence have been recorded, that it must be considered an attribute of bioplasm generally, though in many cases the movement cannot be seen. Not only amoeba and allied forms, destitute of locomotor organs, move actively, but many of the bioplasm particles of man and the higher animals may be seen to move from one situation to another under the microscope. The movement of entire mucus-corpuscles, white blood-corpuscles, and pus-corpuscles, over a space equal to more than twice the diameter of the corpuscle, has been seen by me many times. In white fibrous tissue, in muscle, nerve,

yellow elastic tissue, and some other textures, there is distinct evidence of the movement of the formative bioplasm during the formation of the tissue. In some cases, the bioplasm is prevented from moving from place to place in consequence of being imprisoned in a cavity, but it may continue to move actively nevertheless. Thus, in many plant-cells the bioplasm moves round and round the circumference, just within the cell-wall. Sometimes bundles of fibres are formed by the movement of the bioplasm in the interior of a cell after the cell-wall has been formed. The fibres of the cells of the cartilage of the epiglottis are produced in this way, and I have seen the bioplasm gradually tapering so as to form a delicate fibre, which seemed to have been spun off, as it were, from the bioplasm as it moved round and round the cell-cavity.

Of the several primary vital movements I have described, none can be imitated. They are peculiar to living matter, and not one of them has been explained by physical law. No mere physical or chemical attractions, or repulsions, on the part of any material particle at all resemble vital movements. Neither can these be adequately accounted for by attributing them to changes in the environment, for no conceivable changes outside would cause such movements. Nor is there any machinery in bioplasm to explain the movement.

Of the several movements of living matter I believe those which affect the ultimate living particles of bioplasm never cease. That moving of matter from centre, which involves the movement of pabulum in the opposite direction, I believe to be an essential phenomenon of life. The movement of living particles amongst one another, the movements of a portion of a living mass from the rest, the movement of a living mass as a whole may entirely cease, but I cannot conceive the cessation of motion in a vital centre.

In this lecture I have shown that in all parts of all living beings, at every period of life, are numerous masses of structureless living matter. From the lowest forms of life to the highest, this living matter or bioplasm manifests certain phenomena which cannot be accounted for by physics. Among these purely vital phenomena I have included certain movements which have not been accounted for. These movements are vital, and, as I believe, due to a peculiar power, "vitality."

SCROFULOUS PYELITIS.

By J. J. CHARLES, M.A., M.D., M.Ch.,

Demonstrator of Anatomy, Queen's College, Belfast; and late Assistant-Lecturer on Comparative Anatomy, Edinburgh University.

SCROFULOUS or tubercular pyelitis is a disease of comparatively rare occurrence; and, as the symptoms which attend its progress are often vague and indefinite, especially in the early part of its course, its diagnosis is frequently difficult. The case which I report at length below is one which, during life, excited much interest among the medical men under whose notice it had fallen, partly, no doubt, from its nature having been surrounded by considerable obscurity. The history is nearly complete, many of the details having been written out for me by the patient himself shortly after he came under my care.

History.—A. G., aged 46, latterly a clerk, but formerly a ship-broker (and as such much exposed to changes of weather), married, with a family of ten living children, was first seen by me in consultation in January 1874. I could make out no direct family history of tubercle, but I learned that one or more of his brothers had died of phthisis pulmonalis. In early life, he contracted gonorrhoea, but he never suffered from stricture or venereal sores. His habits were always sober and industrious, and he enjoyed good health until about four years ago, when he received a severe wetting, to which he ascribed the beginning of his illness. This exposure to wet and cold did not seem to have produced any immediate results, for he attended to his business as usual, though not with his wonted vigour. It was some time afterwards, I believe, during the year 1871, that he felt a sudden shooting pain in his left groin; but the exact relation it had, in point of time, to the subsequent hæmorrhages, I am not enabled to say. He appears to have suffered from a pain of a burning or smarting character, over a limited area, in the same region, throughout his whole illness, except occasionally, when it diminished in intensity or disappeared almost entirely under the influence of therapeutic remedies. Micturition also became more frequent, but this symptom does not seem to have given him much concern. On the evening of October 30th, 1871, after running a short distance, he made water; and, to his astonishment and alarm, he discovered that he was passing a large quantity of blood in his urine. He at once sought the advice of a distinguished physician, and was ordered gallic acid and the external application of ice to his loins. Notwithstanding this treatment, blood, almost pure, and to the amount, it is said, of two quarts, continued to come away during the night and greater

part of the next day, when it nearly ceased; but, from that time till his death, the hæmaturia never disappeared entirely except for short intervals.

November 4th. As it was feared that calculi were being formed in the kidneys, bicarbonate of potash was prescribed, and the patient was directed to drink large quantities of linseed-tea.

1872. January 10th. The potash having proved effectual in affording relief, it was repeated in combination with the liquid extract of pareira.

February 6th. The patient now placed himself under the charge of another practitioner of eminence, who prescribed tincture of perchloride of iron, twenty minims, three times a day, and a powder composed of powder of uva ursi twenty grains, and compound ipecacuanha powder five grains, to be taken daily. In addition, he afterwards ordered him an expectorant mixture for the cough, which had annoyed him for some time.

March 5th. After one or two examinations with the sound, it was concluded that there was no stone in the bladder; but, on account of the severity of the symptoms, the existence of a tuberculous ulcer of the bladder was considered highly probable. He was ordered bicarbonate of potash with ipecacuanha wine and tincture of morphia.

April 20th. At this time, the urine had improved somewhat, but the cough had become more severe. During the summer, the patient went to the seaside. Here his general health improved considerably; but the irritability of bladder and the cough still continued, and there was almost invariably a small quantity of blood in his urine.

1873. February 4th. A distinguished local surgeon, under whose care A. G. now came, examined him carefully, but could discover neither stone, enlargement of prostate, nor any tenderness on pressure over either kidney. The diagnosis arrived at was chronic cystitis, with tubercular deposit in the lungs. At this time, his appetite was failing, his cough very troublesome, and his expectoration frequent and copious; there was also constant pain in his bladder, and frequently a brick-like deposit in his urine. He was directed to apply a belladonna plaster, eight inches by six, over his loins, and to take ten minims of dilute nitro-muriatic acid thrice daily.

During the remainder of the year, the patient's condition appears to have become gradually worse, and any improvement effected by medicines was only temporary. On one or two occasions, I believe, he had retention of urine, which had to be relieved by the catheter. At different times during this period he was prescribed aromata sulphuric acid, iodide of potassium, tincture of perchloride of iron, and decoction of pareira. In December, small calcareous particles about the size of mustard-seeds were discovered in the deposit from his urine. They resembled pieces of hardened mortar, and, on analysis, proved to consist chiefly of the triple phosphate (phosphate of ammonia and magnesia), with a small quantity of phosphate of lime. None of these calculi (?) had ever been found before; though, at his physician's request, the patient had regularly looked for them with great care since the first attack of hæmorrhage.

1874. January 3rd. To-day I examined A. G. for the first time. He looked pale and anæmic, with an anxious expression of countenance. For some time past he has had profuse night sweats; his weight at this time was eight stones 10 lbs., his average weight in health being 9 stones 4 lbs. He could not retain his urine longer than a few hours; and, of late, on some occasions, it came away quite freely, but, at others, much straining was required. During the last three weeks, however, he had noticed a change for the worse in this respect; for, although his bladder would occasionally retain urine three hours, or even three hours and a half, yet, on making the slightest exertion in the intervals, such as coughing, rising up, or going to walk, his urine passed away involuntarily. The expulsion of urine had also become more difficult, and, to facilitate the process, he was often forced to sit upon some projecting body, such as the end of a staff, or his heel, to press up the bladder. He spoke of three kinds of pain which annoyed him. The first was a general soreness and sense of weakness in his loins, sacrum, and bladder; the second was a special pain or uneasiness in his left loin, which he likened to the sensation following the application of a mild mustard-poultice; and the third was a peculiar pain or soreness over the left side of his bladder, which, as I have mentioned above, had existed to a greater or less degree from the beginning of his present illness. These three varieties of pain were totally different in character, and might exist separately or together. He stated that his bladder was so morbidly sensitive on the left side some time ago, that if it contained much urine, and he turned on that side in bed, the pain there became so excruciating that he was often obliged to change his position at once; but he did not experience this feeling if his bladder happened to be empty at the time. At present, this pain, though diminished and somewhat modified, annoyed him to only a slight degree after his bladder had been emptied; but, when it became filled again, he was

compelled to empty it at once to obtain relief. At night, his bladder was more irritable than during the day, so that he could not sleep longer than one and a half to two hours consecutively, the accumulated urine giving rise to such pain or dreadful dreams that he was glad to get up. After passing urine, he had not felt any pain at the neck of the bladder or in the glans penis, except on a few occasions; nor had he observed at any time a sudden stoppage to the flow of urine, or any retraction of the testicle. Walking or carriage exercise did not seem to have any influence in increasing the quantity of blood in the urine.

Usually, a little more than the average quantity of urine passed in the twenty-four hours (fifty to seventy ounces); it was acid, of a reddish colour, and specific gravity 1020; there was a thick creamy deposit, which, on standing, formed about one-tenth of the total quantity of urine passed; there was very little albumen in the clear supernatant portion, and this most likely due to the blood and pus mixed with it. The deposit, under the microscope, seemed to consist of pus, mucus, and blood-corpuscles; no tube-casts of the kidney were discovered. On making him pass urine, I noticed that at first it was clear, but near the last it became thick and whitish, and finally consisted of almost pure blood. This difference was well shown if the first and last portions were discharged into two vessels, as Sir H. Thompson has recommended (*Clinical Lectures*, page 11, 1869). The quantity of blood in a particular specimen of urine appeared to be proportioned, as a rule, to the amount of straining at the end of micturition. On passing a catheter, and afterwards a sound, a slight obstacle was met with at the neck of the bladder, as if from enlarged uvula vesicæ; but no stone could be detected after the most careful exploration.

January 6th. I used the sound to-day again with the same result as before; but, on moving the point of the instrument over the left side of the bladder, the mucous surface was felt rough and irregular, and depressed into a pouch near the entrance of the ureter, where the interior seemed to be most sensitive. Rectal examination was also made whilst the sound was in the bladder, but only negative results were arrived at either as to the presence of a stone or enlargement of the prostate. His bladder was then "washed out" with tepid water by means of a silver catheter, to which was attached a long India-rubber tube, having a funnel connected with its opposite or free end—an apparatus recommended in Bryant's *Surgery* (page 501). His bladder was by this means found to hold five ounces and a half of liquid. The patient derived much comfort from this procedure. A gum-elastic catheter was next retained in the bladder to remove the urine *guttatim* as it entered, a plan proposed, I believe, by Sir H. Thompson (*op. cit.*, page 179). The urine that thus came away was almost clear and free from blood and deposit. There was no marked tenderness on pressure over either kidney. The bowels were costive of late, with a good deal of tenesmus; and the stools often contained scybalous masses, the passage of which intensified the pain in the bladder. There was tubercle in the apices of both lungs. His cough and sputa had lately been much augmented; and progressive emaciation and loss of strength were too plainly visible. The patient was recommended to remain in bed for the next week at least, and to take a warm hip-bath every other night; his bladder to be injected with tepid water once or twice a day, and a mustard-poultice to be applied over the hypogastric region. He was ordered:

R. Liquor potassæ, one drachm and a half; tincture of hyoscyamus, six drachms; infusion of buchu, to eight ounces. M. Half an ounce to be taken three times a day;

And a suppository containing half a grain of hydrochlorate of morphia to be inserted before going to bed.

January 12th. The morphia suppository was not repeated, as it did not produce the desired effect, the patient seeming to have a peculiar idiosyncrasy for opium; all preparations of it, he said, generally giving rise to sleeplessness or uneasy dreams. I prescribed:

R. Tincture of hyoscyamus, succus conii, of each six drachms; fluid extract of pareira, tincture of buchu, liquor potassæ, of each one ounce; decoction of pareira, to eight ounces. Half an ounce to be taken three times a day; also four grains of compound ipecacuanha powder three times a day.

To assuage thirst at night, he was advised to drink linseed-tea, or a solution of the acid tartrate of potash.

January 14th. As nausea and vomiting followed the administration of one or two of the powders, their use was discontinued. There was a manifest improvement in all his symptoms; but the pains in the bladder were still complained of. At Dr. Redfern's suggestion, the skin above the bladder and over the kidneys was painted once or twice a day with tincture of iodine (*B. P.*)

January 17th. The patient now learned to wash out his bladder himself, using the apparatus mentioned above, only substituting a flexible, for the silver, catheter. He washed out his bladder once or twice a

day after passing urine, and from this procedure experienced much relief. He was ordered:

R. Tincture of hyoscyamus, one ounce and a half; liquor potassæ, one ounce; decoction of pareira, to eight ounces; half an ounce three times daily. For the cough, which was very distressing, an expectorant mixture of squills, ipecacuanha, and compound tincture of camphor, was prescribed.

January 21st. The urine was nearly clear, and contained little albumen or deposit, the pain in the bladder and loins was greatly relieved, and the cough was less troublesome. The application of tincture of iodine was ordered to be persevered in, and the mixture of hyoscyamus and pareira to be renewed and taken two hours after meals. To improve the appetite, I prescribed quinine in small doses, to be administered with or immediately after meals, so as not to interfere with the pareira mixture. The urine remained slightly acid, though large quantities of potash had been taken lately.

January 24th. The patient was not so well as on the last occasion. The deposit in the urine had increased.

January 29th. Some improvement was visible to-day, though he complained of indigestion, for which tincture of perchloride of iron with sulphate of quinine was ordered. Up to this date, he had been taking cod-liver oil occasionally, and he believed it relieved his cough.

January 30th. Blood reappeared in the urine, mixed up with the liquid, and in the form of a few clots, most of which were long and narrow, like earth-worms, and the rest short and broad. As the patient remained quietly at home for the last fortnight, he knew of no cause for the return of the hæmorrhage; he remarked that rest or exercise appeared to have no direct influence upon its occurrence; it seemed to come on spontaneously.

February 7th. To enable him to sleep more comfortably at night, and to alleviate the irritability of the bladder, syrup of chloral-hydrate was prescribed in thirty-minim doses, to be increased if necessary. He wore a large Crimean plaster across his loins, from which he experienced much relief to the feeling of weakness in the back.

February 17th. Syrup of chloral-hydrate was given in sixty-minim doses. As balsam of copaiba had been found to act beneficially in chronic inflammation of mucous membranes, I thought it advisable to apply it locally to the interior of the bladder. Accordingly, an injection was prepared, containing balsam of copaiba, decoction of pareira, and tincture of opium. The mixture of tincture of perchloride of iron and sulphate of quinine was repeated. The patient went out every fine day for a few hours.

Feb. 19th. As pain was now complained of in the perineum as well as in the other parts, a mustard-poultice was applied and afforded relief.

February 23rd. The patient stated that, in his experience of different medicines during his present illness, the greatest improvement always attended the use of alkalies. I recommended him to leave off the use of all medicines, and to confine himself to bicarbonate of potash or soda, which he could take in water alone, or with a small quantity of tartaric acid; solution of acid tartrate of potash was ordered to be also drunk occasionally to allay thirst.

February 25th. The urine was nearly neutral, pale, of specific gravity 1010; no deposit or albumen was present; only a few mucus-corpuscles were visible under the microscope, and the amount of blood was diminished. The control over the bladder was greater, and the pain in it less. He still used the injection occasionally, and with apparent benefit. The bowels were costive, but the general health was somewhat better. Notwithstanding this improvement, blood reappeared in a very unexpected manner. I quote from a letter which I received from him on the occasion. "As my bladder emptied itself very frequently this day, and as any time I had occasion to make water it appeared pretty good, Dr. Charles can judge of my surprise, when, in preparing for the washing out this evening, all that is in the cup accompanying this came away at once, completely choking up the instrument. As it is so copious, and appears somewhat different from former discharges, I think it well to send it. Notwithstanding this, my bladder, I thought, had a soothed feeling this day, as if it was getting better." The tea-cup he sent was filled about one-third with clots of blood of different sizes, the majority of them being long and narrow casts, I believe, of the ureter. I ordered one-twelfth of a grain of strychnine in extract of gentian twice or thrice daily.

March 7th. Latterly, although the patient drank a smaller quantity of liquid during the night than formerly, he was obliged to urinate as frequently as ever. The bowels were costive. As his appetite continued to fail, the potash was given over, and the quinine resumed. The injection of copaiba was followed by pain in the bladder and greater deposit in the urine, though at first the patient thought it gave him ease. I ordered an injection of which I had heard Dr. S. Browne speak very highly:

R Tannic acid, one drachm; aqueous extract of opium, six grains; chloral-hydrate, one drachm; water, to eight ounces.

Also syrup of chloral hydrate one drachm at night on going to bed.

March 13th. He had vomiting before, as well as after, meals, and frequent diarrhoea. The pulse, which had been quick for some time, was now 120. He had less pain over the bladder last evening, and only a small deposit in the urine. The injection of tannic acid caused some pain, but the patient thought he had more power over his bladder, and required to urinate less frequently. Even with large doses of chloral hydrate, two or three hours was the maximum period of rest he ever enjoyed. Anorexia increased, cough became worse, expectoration very profuse, but not streaked with blood. I ordered compound kino powder, one drachm, to be divided into twelve powders, and one taken every third or fourth hour till the diarrhoea should cease; a warm bath at bed-time; and mustard-poultice to the epigastrium if vomiting continued.

March 20th. From this time, A. G. gradually sank. Emaciation proceeded apace; the cough was still violent; his appetite was almost completely gone; vomiting and diarrhoea were frequent. The perspirations had ceased since January 4th, and his bladder did not seem to trouble him so much as formerly. He continued, however, to attend to his business for two or three hours almost every day. To assist his digestion, pancreatic emulsion (Savory's) was administered, but it did not appear to do him much good.

April 21st. During the last week, he ate no food, and lay in bed almost unable to move from weakness, complaining of great pain in his bowels and bladder. About 1.30 P.M. he got his bladder washed out with tepid water, and expressed himself greatly eased. Half an-hour afterwards, he died very quietly. [I may mention that, two days before his death, A. G. requested me, for the sake of science, to make a *post mortem* examination of his body, as something, he said, might thereby be learned likely to prove of service to some fellow-sufferer.]

Necropsy, about twenty hours after death.—As only a short time was allowed, my examination was necessarily confined to the urinary organs. The peritoneum, especially that portion over the bladder, was studded with milary tubercles, and the small intestines were empty and congested, and some of them firmly adherent to the bladder. The kidneys, ureters, and bladder, were removed for further examination. The *right kidney* weighed 6½ ounces, and was large, soft, and flabby. The capsule was whitish and opaque, and could be easily peeled off, leaving a smooth pale surface except at one spot on the anterior surface, where the capsule dragged with it part of the substance of the kidney. On section, two of the middle pyramids, as well as the cortical substance outside them, were seen to be of a pale white colour, standing out in marked contrast to the rest of the substance of the kidney, which was somewhat congested. The mucous membrane of the pelvis was smooth and of a dead white colour, but without any deposit. The *left kidney* weighed 5¼ ounces, and was soft and lobulated. The capsule was much thickened, opaque, and very firmly adherent, and the cortical surface very rough and irregular. On section, the pelvis was found immensely dilated, so as to form a large anfractuous cyst, filled with a soft putty-like mass. The degenerate secreting tissue of the kidney surrounded this cyst in a thin layer, and presented a number of deposits of caseous material like that contained in the cyst with which they were continuous. The mucous membrane of the pelvis was of a dull white colour, with villous processes, and of semicarilaginous consistence, and nearly three times its normal thickness, and had a few calcareous crusts adherent to it. The putty-like mass in the pelvis was shown, under the microscope, to consist in great part of round and somewhat shrivelled corpuscles, like those of pus; there were also granular matter in large amount, flattened and columnar epithelial cells, crystals of triple phosphate and uric acid, and fatty granules. The material found in the secreting substance of the kidney presented almost the same appearances. When the putty-like mass had been entirely removed, the kidney weighed only 1½ ounces. The *right ureter* appeared normal. The *left ureter* was dilated, for the upper three inches, to one and a half times its normal diameter, and its walls were very much thickened, so as to feel almost like a portion of vas deferens. There was a lymphic exudation around it, well supplied with blood-vessels, forming a distinct coat. In its interior, was a thick white material, similar to that in the kidney, but considerably more solid, which extended downwards nearly five inches below the kidney, blocking up the canal entirely; but, beyond this, no obstruction in the ureter was visible. The mucous lining of the upper portion of the ureter was thickened, and covered with small villous processes, that could be scraped off; and, in some parts of it, there were minute depressions resembling those of the mucous membrane of the gall-bladder. A few calcareous crusts were attached to it. The *bladder*. The walls were so thin and soft, that they tore across

on breaking the adhesions between them and the small intestines. The cavity was small, holding only five or six ounces. The inner surface was in some parts irregularly ulcerated and greatly congested, and there was a papillary hypertrophy of the undenuded portions of mucous membrane. The right ureter opened on a vascular papilla, whose width and height were nearly equal and about a quarter of an inch.* The left ureter terminated in the usual way. The *vesiculae seminales* were dilated, more especially the left; and both were filled with purulent matter, which could be pressed from them into the urethra. The *vasa deferentia*, for the last two inches of their course, were enlarged, their walls thickened and softened, their interior filled with a soft thick tuberculous matter, and their mucous lining covered with villous projections. The common ducts of the *vesiculae seminales* and *vasa deferentia* were so much shortened and widened, that the ducts of the vesiculae and those of the vasa deferentia seemed to open separately into the urethra. The apertures of the vesiculae were large enough to admit a large probe. There was much low inflammatory exudation around the vesiculae, that caused their dissection to be rather difficult. The *prostate* was involved in the disease. The prostatic portion of the urethra was dilated, and the verumontanum, where the seminal ducts debouched, was excavated as if by small abscesses.

REMARKS.—*Résumé of Salient Points in the History and Post Mortem Appearances.*

1. No history of syphilis, but gonorrhoea in early life.
2. Four years before death, exposure to wet and cold, to which the beginning of the illness was attributed. General health then commenced to show signs of decay; and among the symptoms occasionally present during the following year, were pain in the left groin and frequent micturition.
3. Sudden and almost painless attack of hæmaturia two years and a half before death; the hæmaturia and the frequency of micturition almost persistent.
4. No calculi ever discovered in urine, though diligent search made for them. Small mortar-like masses were sometimes found during the last year of the patient's life. These were composed of the triple phosphate with a small proportion of phosphate of lime, and appeared to be hardened portions of a deposit in the pelvis of the kidney which had been passed in the urine.
5. Pain complained of across the front, the left side, and the base of the bladder, as well as in the loins.
6. Urine acid, sometimes neutral, but scarcely ever alkaline, even after prolonged use of alkalies; purulent deposit in variable quantity for last year and a half.
7. Tubercle in lungs, in all probability, for nearly two years before death.
8. Milary tubercles on peritoneum.
9. Walls of pelvis and portion of ureter of left kidney thickened; cavity enlarged, and filled with a putty-like mass of caseous material. Secreting substance of kidney diminished in bulk, and containing caseous matter continuous with that in the pelvis.
10. Right kidney enlarged and congested; pelvis and ureter nearly normal.
11. No visible obstruction in either ureter; but the caseous material in upper part of left ureter may have sometimes acted as a plug.
12. Inflammation, tubercular ulceration, and suppuration of bladder, vesiculae seminales, and vasa deferentia.

Diagnosis.—In this case, there can be little doubt the disease began in the kidney (pyelitis), and spread downwards to the bladder. But there are several varieties of chronic pyelitis. Sir H. Thompson speaks of three kinds (Holmes's *Surgery*, vol. iv, p. 869): 1, calculus; 2, scrofulous; 3, from obstruction; to which we may add from Roberts's classification (Roberts, *Urinary and Renal Diseases*, p. 451): 4, "from extension upwards of inflammation from the bladder"; 5, "from cold and unknown causes".

In this case, the pyelitis did not arise from "obstruction" in the ureter, for we have no evidence of this at the beginning of the disease. Neither did it result from "inflammation extending upwards from the bladder", as the earliest symptoms pointed to the kidney. Moreover, the necroscopical examination showed that the morbid process had advanced much further in the kidney than in the bladder. Nor are there any satisfactory reasons for saying it arose from "cold and unknown causes" alone, since "it is very rare that pyelitis is not secondary to some antecedent morbid process or mechanical irritation" (Roberts, *op. cit.*, p. 452), though the exposure to cold may have served as the exciting cause. We have now, therefore, only to determine

* In Mr. Ebenerer Smith's case, "opposite the entrance of the ureter to the bladder, was a highly vascular tumour of the mucous membrane, about one inch long and one-quarter wide". (*Pathological Transactions*, p. 79. 1848.)

whether the case under consideration was one of calculous or of scrofulous pyelitis.

In favour of calculous pyelitis (under which we include irritation produced by the presence of a foreign body in the pelvis or infundibula of the kidney, such as calculi, gravel, cancer, hydatids, or blood-clots), we have:

1. The occurrence of severe hæmaturia at the commencement of the disease, which continued to a less degree to its termination. Severe hæmorrhage is rare in tubercular pyelitis; but cases in which it has occurred have been recorded by Roberts and by Thomas Smith (*St. Bartholomew's Reports*, vol. viii, pp. 100-104).

2. The microscopical and other appearances of the putty-like mass were not those of well marked tubercle. But Chambers states that "these large masses (of tubercle), constituting the form of disease called 'scrofulous degeneration', have such a different appearance from the small, hard, shot-like tubercle, that, were they not the consequence of the same diathesis, one could hardly believe in the relation between them" (*Medical Times and Gazette*, 1852, 2nd part, page 403). Dr. McDowall relates a case of tuberculosis of the kidney in which the tubercular matter was of a "dirty white substance.....of the consistence of putty" (*Edinburgh Medical Journal*, vol. xv, p. 1093); and the drawings he gives would almost serve as representations of the kidney under consideration. Besides, a large quantity of pus-corpuscles was mixed up with the tubercular elements in the pelvis; hence the deficiency in the characteristic features; and

3. No ulceration of the pelvis or ureter visible; but there were a few ulcers in the bladder.

Against this theory, and in favour of scrofulous pyelitis, there are the following facts.

1. No calculi were discovered in the urine, though small mortar-like masses were present occasionally during the last year of patient's life.

2. No calculi found in pelvis or ureter at necropsy; and no obstruction in the ureter, except such as might have been caused by the putty-like material.

3. Miliary tubercles on the peritoneum, and, it is believed, in lungs also.

4. Caseous material in the bladder, vesiculæ seminales, and vasa deferentia.

It is clear that the weight of evidence is on the side of the latter hypothesis, though, in the present case, it is possible the whole truth may be in neither theory, but in a combination of both. Thus a calculus formed in the pelvis, after setting up pyelitis in a tubercular constitution, may have been broken down, by the continued passage of acid urine over it, into the particles which were found in the urine in December 1873; and the miliary tubercle on the peritoneum and in the lungs, etc., may have been caused by absorption from the caseous matter in the kidney, the result of the pyelitis. Or microscopic calculi may have existed in the *tubuli uriniferi* (Roberts, *op. cit.*, p. 549) at the beginning of the disease, and have given rise to the first attack of hæmaturia, and afterwards to the pyelitis. It should be mentioned, however, that no such calculi were found at the necropsy. I therefore prefer naming the disease in the present case *scrofulous*, rather than *tubercular*, pyelitis, because the term *scrofula* is the more generic of the two, and includes instances in which there is no well marked tubercular manifestation (Aitken's *Medicine*, vol. ii, p. 2; 1872).

I may here appropriately give the signs by which the pyelitis in this case might have been diagnosed from cystitis.

1. Pains in the loins were amongst the earliest symptoms.
2. There was profuse hæmorrhage at the beginning of the ailment.
3. A large quantity of pus, etc., almost always appeared in the urine.
4. The urine remained acid, though alkalies were administered for some time (Roberts, *op. cit.*, p. 134). Exceptional cases, however, occur in which the urine is alkaline (Thos. Smith, *op. cit.*, pp. 100 and 102). In cystitis, the urine is eventually alkaline from ammoniacal decomposition.

5. Long vermicular clots of blood were passed in the urine.
[6. At an early period, pelvic and infundibular epithelial cells might possibly have been discovered in the urine.]

The sequence of events in this case, it must be admitted, is rather obscure; but, in all probability, it was somewhat as follows. The patient being of the tubercular diathesis, the exposure to wet and cold acted as the exciting cause of a deposit of tubercle in the secreting substance and in the submucous tissue of the pelvis of the left kidney (tubercular pyelitis). Severe hæmaturia occurred in consequence (or, less likely, from the presence of minute calculi in the *tubuli uriniferi*, or from calculus of the ordinary size in the renal pelvis). The inflammation set up by the tubercle spread down the ureter; and the constant passage of urine, carrying pus and blood, excited cystitis, with subsequent tubercular deposit (Rindfleisch). The vesiculæ seminales

and vasa deferentia were next affected; but it is difficult to say whether the disease in them gave rise to the pain suffered by the patient on the left side of the bladder. There was not much pain, however, complained of when pressure was made upon them from the rectum. Then the ureter, whose calibre had been already diminished by the thickening of its mucous membrane, underwent temporary occlusion from a clot, when *pyosphrosis* was produced, which terminated in desiccation of the pus and other materials, and in the formation of a putty-like mass.

The blood which appeared in the urine at different stages of the disease came from almost all parts of the urinary mucous membrane. At an early period, as well as throughout the whole course of the disease, it was derived from the secreting substance, pelvis, and ureter of the left kidney; and it passed off nearly pure, as in the severe attack of hæmaturia, or formed the vermiform clots in the ureter, which were expelled at a later stage, or was intimately mixed up with the urine. It is possible that blood also came occasionally from the right kidney, as a consequence of congestion produced by the extra work thrown upon it by the growing degeneracy of the left kidney and the blocking up of the duct (Roberts, *op. cit.*, pp. 338 and 339). This hypothesis is supported by the fact that the putty-like mass in the left kidney showed no tinge of blood, though the subsequent flow of urine may have removed any such stain. The unmixing blood at the end of micturition no doubt came from the bladder.

The varieties of pain complained of can be readily explained. The general uneasiness across the bladder was the result of cystitis; the pain in the loins and on the left side of the bladder depended on the irritation of the left kidney by morbid materials (pus, tubercle, etc.), and sometimes on the passage of clots and portions of the putty-like mass along the ureter; and the pain in the perinaeum (behind the scrotum) was ascribable to the cystitis, and perhaps to the inflammation of the vesiculæ seminales and vasa deferentia.*

The frequency of micturition from the beginning of the ailment was the consequence of inflammation in some portion of the urinary mucous membrane; and the loss of power at last over the contraction of the bladder is to be attributed to the degeneration of its walls from long continued cystitis and from tubercular deposit. Tubercle was deposited in the lungs about two years before death, and on the peritoneum shortly before it.

Treatment.—I have nothing new to offer in the way of treatment. Tonics of various kinds are the most beneficial remedies; and, of other medicines, none produced more favourable changes in the urine in the present instance than bicarbonate of potash in large doses. Under its use, the blood disappeared, and the pus diminished in quantity. It is possible, however, that the benefit may have been to a certain extent more apparent than real; the alkali having acted chemically on the purulent deposit, and changed it into a viscid, glairy, mucus-like mass, so that it was less visible (Beale's *Kidney-Diseases, Urinary Deposits*, etc., p. 363; 1869). Washing out the bladder with plain water always gave relief.

In conclusion, I beg to thank Dr. W. Roberts of Manchester most cordially for his kindness in examining the kidney in this case, and for his valuable opinion upon some of the difficulties connected with the diagnosis. Sir H. Thompson and Mr. Thomas Smith of London also merit my best thanks for their useful suggestions.

A CASE OF CONTRACTION OF THE LOWER EXTREMITIES, WITH MUSCULAR WASTING AND COMMENCING ATROPHY OF THE OPTIC NERVES.

By ELIZABETH GARRETT-ANDERSON, M.D.,

Physician to the New Hospital for Women.

JANE P., aged 44, single, was admitted into the New Hospital for Women under my care on January 19th, 1875, for contraction of the legs.

The family history gave no trace of serious nervous disease. Her father was always well and strong, and died at 50, of strangulated hernia. Her mother died at 70, of apoplexy. No near relatives have had epilepsy, asthma, or paralysis.

The patient herself has been very delicate and "hysterical" ever since she was 14 years old; at the age of 15, she had an illness described as "brain fever". It was accompanied by severe pain in the head, high

* Professor Verneuil states that the vesiculæ seminales, when inflamed, are hard, voluminous, and painful to the touch, and that incessant painful micturition is one of the most prominent symptoms. (*Clinique: Journal de Médecine et de Chirurgie Pratiques*, pp. 16 and 17. 1874.)

fever, and delirium. Leeches and ice were applied. When consciousness returned, she could not speak. She thinks now that the difficulty lay in the articulation of words; she says she had to learn to speak again like an infant. It is, however, evident, from her own account, that there was also some aphasia, even if the loss of speech were not entirely aphasic. There was no paralysis of the tongue or of the muscles of the mouth; she was in good health; and was able to work regularly as an apprentice to the straw-bonnet trade. Her fellow apprentices gradually taught her to speak again; but for two years she had great difficulty in expressing herself, and would often use one word for another something like it either in sound or in meaning. The catamenia did not appear till she was 20; from this time, the loss was regular and apparently normal till four months ago, when it ceased suddenly. At the age of 22, she had "rheumatism" very badly in her legs. There is no history of swelling of the joints, or of heart-affection. Vapour-baths cured her. At 26, she had an attack of constant crying for nothing. She was not unhappy, but she cried incessantly for three months. From that time to the commencement of the present attack, she was often "hysterical", crying and laughing for nothing, was very nervous, and easily worried, "never good for much".

History of illness.—Seven years ago, she began to notice that her legs were weaker than they had been. The knees would occasionally give way, and the legs felt very heavy and tired. Soon afterwards, she had some aching of the lower part of the spine, and was always glad when she could lie down. The weakness of the legs gradually got more and more marked till April 1874. She had then not lost locomotive power, but she walked with difficulty, and was very soon tired. There had never been any impairment of sensibility in the limbs. In April 1874, the knees began to contract; the contraction increased rather rapidly, and in a few weeks she was not able to walk at all. One month after the contraction began, she went to a hospital, and was there thirteen weeks. Then she went to another hospital; and here chloroform was given, and she was told that the contraction completely disappeared under its influence. While she was in the anæsthetic state, fourteen-pound weights were applied to each foot. This caused intense pain, and in two days a further attempt was made to straighten the limbs by putting them into screw-splints. This also caused very severe pain, and finally the patient discharged herself in September 1874, rather than submit to it. She thinks that the contraction was much worse after those attempts to overcome it.

State on admission.—Both the lower limbs were in a condition of spasmodic flexion; the thighs upon the pelvis, and the legs upon the thighs. The left adductors were also in a state of tonic spasm, so that, while both thighs were flexed, the left one was carried across the right, and the left knee was pressed forcibly against the lower third of the right thigh. The muscles of both thighs were apparently wasted, while to the touch they felt much harder than normal. There was no impairment or perversion of sensibility in either limb; no loss of power over the rectum or bladder; no bed-sores, though the patient had now been confined to bed for ten months. There was no exaggeration of reflex movements. In spite of the contraction the limbs were not entirely without power of movement; they seemed to have some motor power, though it was restrained by the spasm, rather than to be contracted as a result of paralysis. Examination of the spine showed some tenderness over the lower lumbar vertebra; no feeling of burning was perceived on passing a hot or a cold sponge down the spine. No sense of constriction was felt round the body. As to electro-contraction, very feeble contractions were produced by a strong faradisation current; electro-sensibility also was much diminished. After this was tested, the patient thought the contraction was decidedly worse. Chloroform to complete surgical anæsthesia made scarcely any perceptible difference to the contraction. The anæsthesia was maintained for six minutes. The urine was acid, of specific gravity 1024; no albumen. She complained of dimness of sight; she could only read No. 30 Snellen's types. Even this soon became misty. She said she had "dizziness" of the eyes. There was no strabismus. The cornea and media were clear; the pupils equal. Dr. Broadbent, who was good enough to examine the eyes, reported that rather more than the outer half (of image) of the optic discs was unnaturally white, and the centre depressed; the inner segment was fairly vascular. The retinal arteries and veins were rather small. The condition was similar in the two eyes. In the right eye, to the outer side of the disc (distant about three diameters of the disc), and a little below the level of the disc, was an irregular patch, in which the choroid and retina were atrophied and white sclerotic showed through. There was slight inequality of the labial muscles; on showing the teeth, the levator anguli oris on the left side acted less vigorously than on the right; the tongue was protruded in the median line and was well nourished; there was no fault of articulation; the palate muscles acted well and equally. There was no sense of weakness nor any contraction of the arms.

REMARKS.—This case seems to me to belong to the group recently described by M. Charcot, in which the tonic contraction depends upon sclerosis of the lateral columns of the spinal cord. In some respects, however, it does not agree with M. Charcot's account. In the cases he has observed, the rule has been for the upper limbs to be the first affected; for the contracted limbs to be in the position of extension; and for wasting of the muscles not to appear early in the lower limbs. In my case, the arms are at present, after ten months' contraction of the legs, quite unaffected; the legs are rigidly flexed, instead of being extended; and there is decided muscular wasting. I have also not observed the trembling of the affected limbs which M. Charcot mentions as a prominent symptom. But, though exceptional in these particulars, I think M. Charcot would accept the case as one of sclerosis of the lateral columns. The diagnosis lies between this and hysterical contraction. As bearing upon the at present unknown pathology of hysterical spasm, it is interesting to note that, so recently as in August 1874, the contraction is said to have disappeared under chloroform; and if this be correct, it might at that date fairly have been described as hysterical. M. Charcot seems to recognise that hysterical spasm may run into the permanent spasm of sclerosis, and this may have been the sequence of events here. If it be true, as maintained by M. Charcot, that tonic muscular contraction means always disease of the lateral columns, either primary or consecutive upon cerebral or upon other spinal disease, it may be that hysterical spasm depends upon some temporary impairment of nerve force or of conducting power in part of the lateral columns, by which the affected part is rendered as useless for the time being as it is permanently in sclerosis. Moreover, if it be found clinically that contractions once hysterical do frequently go on to the permanent contraction of sclerosis, there would be reason for suspecting that the pathological condition of the cord in the two conditions must be related to each other. The muscular wasting, and the loss of electro-contraction and electro-sensibility, indicate, according to M. Charcot, that the sclerosis has extended from the lateral columns to the anterior cornua of grey matter in the cord.

The case does not seem to me to admit of treatment. Electricity in any form is, I imagine, distinctly contraindicated. Tonics and counter-irritants to the spine are not likely to be of the smallest benefit. Cod-liver oil and a little bromide of potassium have been given to help nutrition and to procure sleep. With the view of testing the effect of conium on permanent spasm of this kind, large doses, *i.e.*, four and five drachms of the succus (Bell's), have been given repeatedly. As might have been anticipated, the effect was *nil*.

The propriety of performing tenotomy on the contracted tendons was considered; and, as there seemed to be no reasonable probability of its affecting the tonic muscular spasm upon which the contractions depend, the operation was not advised.

ON THE VALUE OF TAR IN BRONCHIAL CATARRH AND WINTER-COUGH.

By SYDNEY RINGER, M.D., *Unif. Col. Lond.*
Professor of Materia Medica and Therapeutics in University College, London; and
WILLIAM MURRIEL, L.R.C.P.

THE frequent and popular use of this remedy, both by the profession and by the laity, in France and Belgium, led us to try its effects. Patients so susceptible to cold, that they were obliged to remain indoors the whole winter, informed us that this remedy curtailed considerably the duration and lessened the severity of their catarrhal attacks, and that, by an occasional recourse to the tar, they became less prone to catch cold, and could more freely expose themselves to the weather, without incurring an attack. It will be seen that our observations confirm these statements.

We employed tar in two-grain doses, made into a pill, every three or four hours. From October to January, inclusive, we carefully watched its effects on twenty-five patients, whose ages varied from 34 to 70, the average being 44. All these patients had suffered for several years from winter-cough, lasting the whole winter. They were out-patients, and visited the hospital weekly, or oftener. Most of them were much exposed to the weather, whilst some were so ill, that they were obliged to stop work, and, therefore, were less exposed.

These patients suffered from the symptoms common in winter-cough—paroxysmal and violent cough, the paroxysms lasting from two to ten minutes, and recurring ten to twelve times a day, and, in the night, breaking their rest. The expectoration, frothy and slightly purulent, was generally rather abundant, amounting in some cases to half-a-pint or more in the day. The breathing was very short on exertion, but

most could lie down at night without propping. The physical signs showed a variable amount of emphysema, with sonorous and sibilant rhonchus, and occasionally a little bubbling rhonchus at the base.

These patients usually began to improve from the fourth to the seventh day; the improvement rapidly increased, and, in about three weeks, they were well enough to be discharged. The improvement was so decided, that the patients returned to their work; even those who in previous years had been confined to the house the whole winter. The cough and expectoration improved before the breathing. In several cases, the expectoration increased during the first three or four days; but its expulsion became easier, and, with the improvement in the cough and expectoration, appetite and strength returned.

On discontinuing the tar, a relapse often occurred in a week or two, and the patients returned with a request for more of the same medicine, and then, a second time, the symptoms quickly subsided. We found it useless in bronchial asthma, and its effects were more evident in cases where expectoration and cough were more marked than dyspnoea.

We have no doubt that tar is a good, useful, though, perhaps, not a striking, remedy in these troublesome affections; and certainly it is more efficacious than the drugs generally employed.

It may be remarked, that tar is useful in the same cases for which the spray of ipecacuanha wine is serviceable. The spray, we find, acts much more quickly, and, unlike tar, it lessens dyspnoea even before it improves cough or diminishes expectoration.

We have this year continued to carry on our observations with ipecacuanha wine spray, and with results confirmatory of the statements made in August last. We find, however, that some patients are very intolerant of ipecacuanha spray, which causes in them a good deal of irritation, and even tightness of breathing. It is advisable, therefore, at first to dilute the wine with one or two parts of water: a precaution especially needful for patients affected with much dyspnoea, with lividity; for the spray may for some hours much intensify the difficulty of breathing and lividity, so as to alarm the patient and friends.

It may be not much out of place to mention here that, in several cases, we have found the spray very serviceable in non-febrile inflammatory sore-throats, the mucous membrane being swollen and very red. We have found it useful, too, in hoarseness from congestion of the vocal cords. Where the hoarseness has lasted a few days only, or one or two weeks, the spray often speedily cures; but, where the hoarseness has persisted three months or longer, the spray even improves the voice considerably, but some hoarseness remains.

(Brit. Med. J. Internal)

THERAPEUTIC MEMORANDA.

DOSES OF CAMPHOR.

I AM still of the same opinion as when I wrote to the *Times*. It must not be forgotten that the dose is marked on these bottles "from three to five drops", which will contain about two and a half grains of camphor; and in such doses, if there be nothing but camphor, they may be taken with impunity.

I have received the following letter.

"2, East Parade, Rhyll, March 11th, 1875.

"Sir,—I trust you will excuse the liberty I am taking; but, having read the letters in the *Times* March 5th, and your reply on the 6th, also the rejoinder on the 8th, I send you the copy of a prescription I was told of above thirty-five years ago by a London practitioner who had used it for very many years, and I have used it ever since. R Camphoræ gr. x; spr. vini rect. q. s. ut fiat pulvis; pulv. acaciæ gr. xv; tincturæ opii ℥xx; tincturæ lavand. co. ʒss; aquæ ʒx. M. fiat haustus. This is the best draught I ever used after confinement for after-pains. If the patient could not bear the tinctura opii, I omitted it. I almost invariably gave it with the tinctura opii with the very best results, and never had any unpleasant symptom or mischief produced by it. I have found it extremely useful in painful menstruation or irritation of the uterus. It is unfortunately given just in the state, 'the minute subdivision,' said by the physician to be more poisonous. But, after my long experience of its use, I should not give it up upon the mere *ipse dixit* of any person. You are perfectly at liberty to make use of this letter, if you think proper.—I am, sir, your obedient servant,

"G. J. S. CAMDEN, M.R.C.S."

Allowing that opium and camphor are to a certain extent antagonistic, I think the above letter is sufficient to condemn the statement in last week's JOURNAL that camphor is absolutely "poisonous, drop by drop, as the prussic acid of the *Pharmacopœia*". C. R. BREE, M.D.

CLINICAL MEMORANDA.

EPIDEMIC JAUNDICE.

IN common with many parts of England, we have had influenza at Stamford to a very great extent since last October. During the progress of the malady, it has been interesting to notice how much catarrhal inflammation of the various mucous membranes has prevailed. In the epidemic, one of the most curious facts was acute jaundice in children. I had fifteen cases in my own practice, in children under 10 years of age, during November and December last, and I heard of others. The digestive tract of mucous membrane was nearly as much affected by the influenza as the respiratory tract, mucous diarrhoea being most common. There can be no doubt that the jaundice was caused by catarrh of the bile-ducts. The disease set in soon after the intense chill; there was often shivering at the commencement of the influenza. The disease was analogous to the jaundice one sees associated with ague in the adult, and which one regards as depending upon active congestion of the liver. Unlike jaundice connected with ague, the jaundice of my cases was more amenable to treatment. No case lasted more than three weeks. The recovery was perfect. Epidemics of jaundice are rather unfrequent, and, when they do happen, it is well to record them for future reference. In Mr. Simon's Sixth Annual Report to the Privy Council, there is an interesting account by Dr. Ord of an epidemic of 2,300 cases at Rotherham in 1863.

J. M. HEWARD, Medical Officer of Health, Stamford.

THE RELATION OF CROUP AND DIPHTHERIA.

THE following cases, which have recently fallen under my notice as medical officer of health, tend, I think, to corroborate Sir William Jenner's theory of the identity of croup and diphtheria. About the middle of January, I was informed of a death from croup in a village about a mile and a half from this town. Hearing that members of the family generally suffered from "bad" throats, I analysed the well-water, and found it polluted with sewage. On inspection, I found the drainage most faulty, allowing easy percolation into the surrounding soil. I was informed by the medical attendant that, in this case of "croup", not a speck was to be seen in pharynx or fauces. During the ensuing week, a boy from the same house, who had recently returned to a large school a mile and a half on the other side of the town, complained of his throat; the same medical man saw him; the ailment appeared but slight. A few days afterwards, I was requested by the ordinary medical attendant of the school to visit and inspect the place, as he had a very bad case of diphtheria under his care, which in a few days ended fatally. On inquiring into the cause of the disease, I found that on the Sunday before the patient had been for some hours in the hospital ward with the boy previously mentioned. The water-supply of the school was pure, and the sanitary conditions fair. There was no other case. It appears to me that the evidence of direct infection is clear, from the "croup" case to his elder brother at school, and from him to his schoolfellow, whose case terminated fatally. At the same time that this was taking place at the school, another child in the house where the croup first occurred was attacked with genuine diphtheria, and died.

HENRY J. ALFORD, M.D., Taunton.

SURGICAL MEMORANDA.

SPINA BIFIDA.

IN the BRITISH MEDICAL JOURNAL of March 13th, I observe in the Surgical Memoranda, "Case of Spina Bifida treated by Injection of Solution of Iodine: Death," by Mr. J. E. Burton of Liverpool. The result will not surprise any one who notes the nature of the case. It belongs to a class of cases all but absolutely hopeless, in which the lower limbs and lower part of the trunk of the body are paralysed, and the infants usually die in a few days. Instances of longer survival are rare indeed, and I am not aware that there are any on record in which the paralysis was so very extensive as in Mr. Burton's case. When speaking of such cases to my clinical students, it has been my habit to exclude paralysed cases as unfit for operation; and, though an occasional exception to this rule may occur, it is very likely that I would have declined to treat such a case as Mr. Burton's. I have to thank him, however, for relating it; for, *quantum ad id*, it confirms the rule referred to, and also shows that, even in such hopeless conditions, no immediate bad effect followed the use of the iodine solution. From the refilling of the tumour, I infer that the cerebro-spinal fluid did not continue to drain away, which it is important to prevent. I may

mention that, at present, I have under treatment a case in which the site of the tumour is the upper cervical region. It was large, translucent, and growing. Five times already has it been injected without a disagreeable symptom. It is hoped the details will soon be ready for publication.

JAMES MORTON, M.D., Surgeon Glasgow Royal Infirmary.

REVIEWS AND NOTICES.

MATERIA MEDICA AND THERAPEUTICS. Vol. I. Vegetable Kingdom. By CHARLES D. F. PHILLIPS, M.D., F.R.C.S.E. Pp. 584. 8vo. London: Messrs. Churchill. 1875.

It has been remarked that some of our most practical therapeutical work has been done by men not holding special appointments, notably by Dr. Rogers and Dr. Waring. The volume before us is another illustration in point. The simplicity of the title-page is a striking feature; there is no list of appointments, no names of previous writings, but the book bears internal evidence of long and careful study.

The plan of the book is excellent for its purpose. There is no attempt at physiological classification; such would be obviously incomplete when the mineral kingdom is not even considered; it would hamper the writer and involve much repetition, as it does so markedly in Neligan. The vegetable kingdom is grouped in botanical orders, and a brief general review of each one precedes the list of its genera that are in use. Under each medicine we have (1) *A Description*, interesting, accurate, and tolerably full without being minute; (2) *Active Ingredients*, giving concise but valuable information on the organic chemistry of alkaloids, glucosides, etc.; (3) *Physiological Action*, described fully when it is of ascertained truth and of importance, briefly when it is doubtful or inapplicable; (4) *Therapeutic Action*; (5) *The best Preparations of a drug*; (6) *its Adulterations*, when important.

In the division, *Physiological Action*, we have much of the special value of the book—its careful résumé of the best and latest foreign work, e.g., Hirtz and Achscharnow on aconite, Marmé on helleborin, Binz (and Baxter) on quinine, Traube and others on nicotine, Roëber on picrotoxine, as well as of the numerous modern writers on curarine, opium, digitalis, and belladonna.

It has been observed that references are somewhat wanting; we find these sufficiently full as regards foreign work, especially in this division; though in (4), on *Therapeutic Action*, some additional ones might advantageously be introduced—e.g., to Mr. Barwell's original paper on strychnia injections, Dr. Clifford Allbutt and others on quinine in fever and pneumonia, Dr. Wilkes on guarana.

These therapeutical sections form an important portion of the book, they are fairly full and detailed, and contain much original observation. We notice, amongst the rest, all the modern uses of aconite, and cases illustrating its value in pneumonia and puerperal fever; full accounts of belladonna in pain, spasm, and inflammation; opium and its alkaloids; apomorphia; digitalis; strychnia in chronic palsies; ipecacuanha in catarrh, hæmorrhage, and dysenteries; ergotin in hæmorrhage, etc. We observe, *en passant*, a recommendation of tincture of colocynth, and an adverse opinion to the virtues of valerianates.

Moreover, the range of the book is not limited by the *British Pharmacopœia*, but "From vulgar bounds in brave disorder parts". It contains interesting notes on pulsatilla in dyspepsia and amenorrhœa, hydrastin in ulcers and purulent discharges, briony in dropsies and pleurisies, sanguinaria in chest-diseases, thus and arnica in rheumatism, etc. On the other hand, no drug has been included simply because it is new; indeed, we miss some that might have been expected, e.g., gelseminum and hamamelis.

The subject of antagonisms is well summarised. That between belladonna and opium is accepted against Harley; also that between belladonna and Calabar bean; Preyer's results as to prussic acid are given, and those of Grisar and others on the oils of camomile and valerian antagonising strychnia.

Under Vitaceæ, we have an account of the "grape-cure".

This arrangement of five or six sections to each separate medicine is adhered to throughout, and each section is headed in large type; so that a clear and easily followed plan is constantly before the reader, and much facilitates reference and comparison; at the same time, a glance shows in what directions the most work has been done, and also—not less important—where knowledge is still wanting. A double index—of remedies and of diseases—complete the volume.

Altogether, the book is well individualised in its scope and character. It is not a student's text-book, crowded with facts and attempting a general view of a vast subject; it is eminently a practical book for the practitioner, interesting and readable. In fact, that we may not raise

any undue expectation in the minds of ultra-scientific therapeutists, we may say at once, that to some it may not seem, in parts, what is called scientific enough. We meet with the expressions—"this is good for such a malady"—"this has given me good results in such a case"—without attempting to reason out an explanation. And yet the author distinguishes cases as much as possible; and, where theory really does help us, it is given; much still in therapeutics must remain a matter of experience. An empirical basis, justly objectionable to a scientific mind when it can be avoided, is yet often our only resource in practice.

But, after carefully reading this book, we see little ground for fault-finding. It is full of information; there is no "book-making"; a vast amount of modern work is smoothly arranged, not too condensed; there are few important omissions; we might wish, perhaps, a little more information e.g., as to capsicin, or we might think the value of copaiva in dropsy to deserve record; sometimes again, as under cocculus Indicus, we are directed only to a "very strong tincture", prepared by certain chemists, when we might wish to have it prepared for us accurately elsewhere; but, on the whole, each subject seems just complete enough.

As to style again, it is, as a rule, very good, and well suited to the subject, though here and there some improvements might be suggested. Thus, the first section, "the aconite family", is not a fair specimen of the whole. "The flowers, in the normal genera, are of simple and intelligible structure"—a mild satire on Nature, we take it, for her construction of the abnormal genera. The concluding paragraphs of the same section, and such a sentence as we find under the therapeutical action of gentian (page 312), are examples of the fault to which we refer. In a less excellent work, they would not deserve notice.

To conclude, of kindred books, it resembles most, perhaps, that of Stillé. It is not quite so full on some points—e.g., of history and physiological action, and contains no general essays on medicinal subjects; but, with all respect to that admirable work of reference, this is more appropriate to the daily needs of the practitioner, it is full enough where fullness is wanted. To our thinking, the author has hit upon a very happy mean. We have reason to know that this is also the opinion of a large number of special workers on the subject. *Laudari a laudatis* is the highest meed, and this Dr. Phillips has amply merited.

NOTE-BOOK OF MATERIA MEDICA AND THERAPEUTICS. By R. E. SCORESBY-JACKSON, M.D. Third Edition, revised by Dr. ANGUS MACDONALD. Edinburgh, 1875.

We come to find in each of the three most popular text-books on Materia Medica—those by Garrod, Neligan, and Scoresby-Jackson—somehow of the respective national characters. The one before us we are accustomed to consider as the very concentrated essence of fact. The number of statements of simple facts, chemical, botanical, and pharmacological, compressed within 700 pages is, to borrow an expression from the book, "truly marvellous".

And, before we attempt to analyse, the question suggests itself, Must one really know all this? How much of this vast array is really available for use? Can we not simplify? Must we put *everything* into our note-book? However, the material being chosen as it is, we must say that it is very well arranged, and very clearly put in different types and paragraphs. The pharmacopœial preparations and tests are printed throughout in italics; and, what is far more important, they are explained neatly and briefly. This is the special value of the book, and one secret of its popularity. That it is popular, the early demand for a third edition is evidence. The editor has left little undone in the way of notice at least of recent work, and has continued to add to the body of fact. The appendix to the *Pharmacopœia* is included; and the chemistry is in the new notation.

The introductory part of this book has always seemed to us specially good. Dr. Scoresby-Jackson was very happy in some of his illustrations. For instance, speaking of the classification of medicines, "It is easier to classify medicines physiologically than therapeutically, because it is easier experimentally to trace the cause of aberration than that of restoration. . . . Suppose a ball to be hanging quiescently at the end of a string, and it is desired to prove that two instruments, when alternately brought near to it, have an opposite effect upon it, the one gradually setting it in motion, the other gradually bringing it to a state of rest. By repeatedly observing the fact, that on the approach of one of the instruments the ball begins to move, at first gently, and then more rapidly, we should conclude that the instrument was the cause of the motion. But of the influence of the second instrument to bring the ball gradually to a state of rest, we should be more doubtful, simply because, if left alone, the ball would of itself become quiescent. In the one case, the proof is positive, in the other, negative."

Again, as to treatment: "Never employ powerful medicines when those of a milder kind will answer the purpose. The more of a man's estate that remains after a lawsuit, the greater is the credit due to his legal adviser, and the more constitutional strength the patient has, at the close of his illness, the more grateful will he be to his physician. Never select a medicine or administer one in such a manner that although the disease may disappear during its exhibition, it may be said of its ultimate effects that they are as bad as, or worse than, the disease itself. When a plan of treatment has been resolved upon, do not impatiently break through it by frequently changing the medicine, in a vain attempt to combat every symptom; and do not cherish the idea that every improvement in the patient's condition is necessarily due to the medicine, and that every change for the worse is attributable to the disease. . . . Always divide the responsibility, by consultation, before pursuing treatment by which life may be placed in jeopardy. Next to his health, be careful of the patient's pocket." Golden rules these.

Turning to the main body of the work, we find it, as already said, very clearly arranged. In the account of the physiological action, there seems too much tendency to rely upon one or more special writers, rather than to place a brief well-digested view before the student. For instance, under Belladonna, Dr. John Harley's views only are quoted, whilst by the profession at large they are by no means endorsed. For the rest, most of the therapeutic work cannot be more than notes; and these require interpretation by a lecturer to be really useful. So large a mass of material requires some guide as to relative importance, and Dr. Harvey's little *Syllabus* might be usefully conjoined.

There is room for some press-correction. Some zinc salts are "nemetonics," and senna has a "glycoside"; and some sentences will bear reconstruction, e.g., "The capability of sulphurous acid (etc.), in the preservation of prepared meat, and of vegetable juices from fermentative and putrefactive changes, is truly marvellous," etc. This word "marvellous" should be used sparingly. We have it again under Aconite, which sometimes gives "marvellously good results in neuralgia"; and again, "Carbolic acid has been administered internally for psoriasis, and this practice so far, seems to have been followed with marvellous success"; a statement, by the way, to which even in this qualified form, we must demur.

However, the general tone of the book is superior to this; and we will conclude with a notice of what we think is really one thing wanting—we mean some general statements as to the great practical classes of medicines. We look in vain for a general explanation of the action, e.g., of diuretics or purgatives, or of the different varieties of these. We notice this want the more, because we felt it much in our own student days; since then, Dr. Garrod has added some very useful classes and commentaries. Neligan, again, has good headings; and similar observations form one of the (few) good points in the abridged Pereira. In the interests of what is really a good work, we venture to suggest some such addition to the accomplished editor, in his next edition of Scoresby-Jackson's Note-Book.

COMMENTARY ON THE BRITISH PHARMACOPEIA. By WALTER G. SMITH, M.D., Dublin. Pp. 766. London: Smith, Elder and Co., 1875.

THIS is a practical, accurate, and sufficiently full explanation of the chemistry of the pharmacopoeial preparation and tests. It includes, also, paragraphs on physiological and therapeutical action, some of them good, but for the most part too brief for criticism. The speciality, perhaps, of the book, is the frequent introduction of tabular arrangements and synoptical lists, e.g., contrasting the various forms of aloes, and again carbolic acid with creasote: thus,

Carbolic Acid.	Creasote.
Derived from coal-tar.	Derived from wood-tar.
In colourless acicular crystals.	Not solidified by intense cold.
Specific gravity 1.065.	Specific gravity 1.071.
Soluble in twenty parts of water.	Very sparingly soluble in water.
Boiling point 370 deg.	Boiling point about 400 degs.
With nitric acid yields picric acid, etc.	With nitric acid yields oxalic acid, etc.

The preparations of metals, etc., are grouped in tables, of which the following one of the ammonias will serve as an illustration:

I. <i>Containing Free Ammonia.</i>	
Ammoniac Liquor Fortior.	Formula, etc.
" " Liquor.	"
II. <i>Haloid Salts.</i>	
Ammonii Bromidum.	"
" Chloridum.	"
" Sulphidum.	"
III. <i>Oxysalts.</i>	

Of which the (a) monobasic, (B) dibasic, (γ) tribasic, are given separately, and the preparations are afterwards described in the above order.

There are also useful genealogical tables of the metals, showing, after the manner of such, the *relationships* of the different compounds, thus:

The idea of the book naturally suggests some comparison with Professor Atfield's *Pharmaceutical Chemistry*. It does not go so fully into the science of chemistry as that work, nor does it give similar experimental processes on chemical groups; it is, in fact, more especially written from the point of view of a medical student or practitioner than of a chemist. We apprehend that a student, who could give the time and care necessary to go through Atfield, would be more *thoroughly* grounded in chemistry than the reader of the book before us: but, on the other hand, this book gives practically all that is necessary, and is calculated to save time and trouble in looking up certain points. It scarcely professes to be a text-book *per se*, it does not give the text of the *Pharmacopœia*, nor all preparations, nor much botany, and thus space is saved; but the official names and headings are retained, and many useful points of information find a place under them. For instance, we have been asked several times about a line on gums caused by bismuth, with the remark "that Garrod and others do not mention it". We find, "according to Brinton, its continuous administration causes a blueish-red line along the edge of the gums, analogous to, but wider and redder than, that resulting from the use of lead". (In no part are detailed references given—only a name.) "The stools are blackened under its use, from formation of sulphide of bismuth." The following sentences express well certain modifying conditions of the action of belladonna.

"1. Children are remarkably insusceptible to its cerebro-spinal effects. 2. Weak and excitable temperaments are more readily and powerfully influenced than the strong. 3. The effective energy of belladonna is inversely as the activity of the renal function. 4. Though atropia is decomposed when left in contact with caustic alkalies, their simultaneous administration does not interfere with the action of belladonna. 5. Acids have no particular influence in this direction."

Under *chloral*, the average dose as hypnotic for adults is put at twenty grains. A brief statement is given of three theories of its action, those of Liebreich, Gamgee, and Byasson. It should be given freely diluted and with some aromatic syrup, or, as we can cordially endorse, with extract of liquorice.

Under *tartaric acid*, we find a note that it covers the taste of quinine, senna, rhubarb, and Glauber's salts; and a reminder that, if "bicarbonate of potash be added to tartaric acid, cream of tartar is immediately precipitated; but, if the acid be added to the bicarbonate, it may be pushed to the point of saturation and yet form a perfect solution".

"Borax is rendered more soluble in water when mixed with cream of tartar, and this mixture has the singular property of inspissating a solution of gum arabic, etc."

These will serve as instances of the mode of putting things; and there are also notes as to history, origin, names, and pharmacy. Altogether, a good deal of useful information is placed conveniently before the eye, and the book well answers to its name of commentary. It may fairly claim a place for itself amongst kindred manuals, and it evinces on every page a considerable amount of careful work on the part of its author. We trust and believe that it will be well appreciated, especially by medical teachers and students.

NOTES ON BOOKS.

DR. AUSTIN FLINT'S *Essays on Conservative Medicine and Kindred Topics* (London, Baillière: Philadelphia, Lea) are a very readable, pleasing, and sound series of essays, reprinted from American serials which they have adorned. The subjects treated are the following: Conservative Medicine, as applied to Therapeutics and to Hygiene; Medicine in the Past, Present, and Future; Alimentation in Disease; Tolerance of Disease; the Agency of the Mind in Etiology; Prophecy.

laxis; Therapeutics; Divine design as exemplified in the Natural History of Diseases. They do not show any striking originality of thought or peculiar felicity of diction; but they are sound, scholarly productions, which may be recommended for leisurely reading.

The Breath, and the Diseases which give it a Fætid Odour, by JOSEPH HART, M.D., from the same publishers, and also by an American author, is a book of a very different class; it has no element of originality or scientific worth. The subject is one which is very well and generally understood, and we can find here nothing to recommend. The semipopular title may perhaps indicate that the book is hardly intended for professional criticism.

The second volume of Dr. HYSLOP's *Cheerful Words*, being sermons for delivery before inmates of lunatic asylums, hospitals, gaols, etc., belongs to a class of literature which we do not criticise, but of which the object sufficiently recommends it. We understand that the first volume has been highly appreciated by those for whose solace it was intended, and hence Dr. Hyslop has been encouraged to produce this second volume, which includes twenty-six sermons. The special feature of these discourses to which the author directs attention is, "that not a single discourse in either the first or second volume of *Cheerful Words* can inspire in depressed minds any other feeling than one of hope, of Christian resignation, and of spiritual cheerfulness". He agrees with Coleridge that, "in the treatment of nervous diseases, he is the best physician who is the most ingenious inspirer of hope".

Fungi, their Nature, Influence, and Uses. By M. C. COOKE and the Rev. J. BERKELEY. Messrs. King and Co. have added another valuable volume to their admirable International scientific series of which they are the London publishers. The authors are the two highest British authorities on the subject treated. It is one which is collateral and often ancillary to some difficult branches of medical investigation. The tendency to connect fungoid growths with the etiology of diseases, at times runs wild; but it does so rather from defect than from excess of knowledge. Our knowledge of many forms of skin-diseases and the means of cure, is largely connected with the study of fungoid forms of vegetation; and the still pending investigations in respect to diseases such as hay-fever, cholera, and typhoid fever, demand an intimate knowledge of the development of unicellular organisms of apparently fungoid character. Mr. Cooke's handbook is, therefore, likely to be largely consulted by medical students and medical men, who desire either to investigate for themselves, or to possess the means of controlling by their own knowledge the stated results of the investigations of others.

Dr. PAYNE, in producing a second edition of JONES and SIEVEKING's *Manual of Pathological Anatomy* (J. and A. Churchill), has probably had at least as much trouble as, possibly more than, in writing a new book. Only those who have tried, can appreciate the labour here undergone of recasting and bringing up to the day an elaborate manual of an intricate subject, which, in the course of several years, has undergone multiform change without arriving at a stage of precision and certainty. It is a sufficiently noteworthy indication of the necessity for the work which he has produced, that, in his labour, he has had to "constantly consult" four treatises, all of which are foreign. Not but that a great amount of good pathological work has been done in this country during the twenty years which have elapsed since the first edition of this book was produced, but it had nowhere been reduced to the systematic form of a manual. We may soon find space for a more detailed review of the admirable result of Dr. Payne's labour; meanwhile, we must express the opinion that this manual, in its present state, and barring some faults, is a very satisfactory, complete, and useful guide.

Dr. WILKS's *Lectures on Pathological Anatomy*, revised and partly rewritten by his successor in the chair, Dr. MOXON (Churchill), are by far more readable, if not always equally reliable. There is a vigour, brightness, and individuality in these lectures which is missing in the manual. This is "Guy's teaching"—excellent teaching—well digested, flowing, sometimes rhetorical, and always hinting an idea while conveying a fact. We should certainly prefer to read "Wilks and Moxon"; but we are inclined to think "Payne, Sieveking, and Jones" the more useful for reference. We prefer the architecture of the former, and the bricks and mortar of the latter. It is a characteristic difference that Payne bristles with references, while Moxon and Wilks rather eschew them. Payne is very shy of theories; Moxon very able and skilful in stating and debating them.

The Transactions of the Medical Society of Pennsylvania, vol. x, 1874 (Collins, Philadelphia). In this handsome volume of transactions are included many papers of considerable interest and value. Among the most noteworthy is a report on one hundred and thirty-two Cataract Extractions by P. D. Keyser, M.D. Vision to one tenth (perfect) was obtained in 86.4 per cent., moderate vision (one tenth to one-twentieth)

in 6.4 per cent.; total, 93.4. In five cases, there was imperfect vision; in four, total loss of vision. Graefe and Liebreich's operations were those most employed. Dr. W. Pancoast writes on a new treatment of Ununited Fractures of the Limbs, and on a new method of treating Intracapsular and Extracapsular Fractures of the Femur by the "Charleston Reclining Chair", which is so made with joints at the points where the hips and knees are supported as to imitate a triple inclined plane, with the additional advantages of movement in an up or down or vertical direction, if passive motion or change of position be required, as it is mounted on little rollers or wheels to move from one place to another. Dr. J. Solis Cohen has an excellent paper on Croup in its Relations to Tracheotomy; and the whole volume is one of great and varied interest.

SELECTIONS FROM JOURNALS.

MIDWIFERY AND DISEASES OF WOMEN.

UTERO-GASTROTOMY.—At a recent meeting of the Medical Society of New York, Dr. Marion Sims made some remarks on utero-gastrotomy—the removal of large uterine fibroids by abdominal section. The operation, he said, stood where ovariectomy did twenty years ago; it had opposition to encounter, and would doubtless achieve the same victory. In America, it had been performed successfully by Kimball, Burnham, Boyd, Storer, and Darby; in England, by Charles Clay, Fletcher, and Lawson Tait. Koeberle of Strasburg cured four out of six cases; while Péan of Paris gives the minute histories of eleven cases, with seven cures; and his pupil Urby says that the whole number of Péan's operations up to the present time is twenty, with fifteen cures. Dr. Sims had recently operated twice for the removal of the uterus, with large fibroid, by abdominal section. The first patient was in a feeble state from excessive loss of blood. During the separation of a large fold of intestine from the surface of the tumour, the capsule of the tumour was torn up, large venous sinuses were opened, and the patient suddenly lost about sixteen ounces of blood. She never rallied, and died from the shock and loss of blood in thirty-five or forty minutes after the operation. The second patient had lost large quantities of blood, and was quite anæmic, but was thought to be a favourable case for operation. It was done on November 9th, according to Péan's method. The patient died in seventy-six hours, of septicæmia. Examination *post mortem* showed the pedicle in a sloughing condition below the wire clamp, the slough extending along the line of incision in the abdominal parietes, and on the top of the bladder, and in the broad ligaments. There were eighteen ounces of bloody serum in the peritoneal cavity. Péan's method of operating is to make a pedicle of the supravaginal portion of the cervix, and to draw this out through the lower edge of the abdominal section by clamp, as in ovariectomy. He transfixes the cervix by a double wire, ties one on each side of the cervix, enclosing the broad ligament on its respective side in the wire. Dr. Sims employed Péan's method in both his cases, but would not use it again; but he advocated the use of the actual cautery. He exhibited a clamp *à ras* on the principle of Nott's (and Isaac E. Taylor's), by which he would compress the broad ligament on one side near the body of the uterus, and then sever the ligament with the cautery down to its junction with the cervix. The same method is to be followed on the side, and then it only remains to cut the tumour from the supravaginal cervix, and cauterise the surface. The several cauterised portions are then dropped into the peritoneal cavity, when, in spite of the eschar, they unite at once by adhesive inflammation to the surfaces with which they lie in contact. Dr. Sims exhibited an automatic alcohol blowpipe for heating the cautery irons. Dr. E. M. Moore of Rochester last summer had a case of uterine fibroid on which he operated successfully, in which the tumour weighed seventeen pounds. The operation was a modification of the one introduced by Dr. Miner of Buffalo, in cases of ovariectomy, and called by him ovariectomy by enucleation. In this case, a pedicle was created by separating a portion of the serous membrane from the surface of the uterus and tumour, and bringing it into the abdominal wound, where it was retained, as in ovariectomy, and formed a cup which received the blood which might escape, and the discharges, and thus prevented their entrance into the abdominal cavity. Dr. Peaslee of New York had seen but two cases in which he thought the operation was advisable; but did not wish to be understood as opposing it. He was perfectly willing to undertake it when the indications were fulfilled.—*New York Medical Record*. *But no record*

THE Earl of Chichester has been elected President of the Sussex County Hospital, Brighton, for the ensuing year.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 20TH, 1875.

THE REPRESENTATION OF IRELAND AND OF THE PUBLIC SERVICES.

WE publish in another column a circular letter addressed to the members of the Irish Poor-law Medical Officers' Association by the Honorary Secretary of the Association, Dr. D. Toler T. Maunsell. The general object of the circular is to sum up the changes of the year in the position of Irish Poor-law medical officers, which has been in some respects improved by the Public Health Act (Ireland) of last session; and to point out what grievances remain, and how they may best be remedied. There is one particular paragraph which concerns the British Medical Association and another great medical body, the General Medical Council. The letter recommends that

"The various great services should be represented upon the General Council of Medical Education and Registration, and also upon the Council of the British Medical Association. The several colleges, societies, and faculties merely, are now represented. These, we do not believe, are in a position to take any interest in their alumni after they have passed through their curriculum. The gentlemen, therefore, who wholly contribute to the funds and expenditure of this body, do not appear to be adequately represented, if at all. We think that the Poor-law Medical Service of the three countries should be represented upon the General Medical Council, and the Army and Navy Medical Service as well. The Poor-law Medical Service in Ireland numbers somewhere about 1,000 medical men, or one-half of the profession; England and Wales, nearly 5,000; Scotland, about 1,000; in all, close upon 7,000 medical officers. The Army Medical Service numbers over 1,000 men, and the Naval about the same. In fact, nearly one-half of the medical men in the United Kingdom are engaged in the public medical services. This arrangement would enable us, through skilled experts, to place our present grievances before Parliament, and perhaps prevent future grievances—a matter which we endeavour to keep always before you."

There is here some little confusion, which tends to obscure the character of the suggestion. The constitution and objects of the British Medical Association and the General Medical Council are so essentially different, that they must be considered quite apart.

The General Medical Council is a Council of Education and Registration. Its constitution is that of a Council consisting of representatives of the bodies which control education and license for practice, and of representatives of the Crown, which directs the public services, and is charged with the general welfare of the public, for whose benefit a monopoly of certain privileges of practice has been granted to the practitioners admitted by the Council to the *Register*. This constitution is open to objection, inasmuch as it is doubtful whether the interests of good education and satisfactory examination and licensing are best guarded by a body consisting exclusively, on its professional side, of the representatives of the bodies which have a vested interest in existing modes of examination. But it is not easy to see how the "services", which, as services, are not at all guided or governed by the Medical Council of Education and Registration, should be separately represented on it in any corporate capacity. With all the grievances which Dr. Maunsell's letter justly enumerates, the General Medical Council is not by its commission or powers at all concerned. It is always well to remember that it is a "Council of Education and Registration"; and that, with the exception of its special charge of the national *Pharmacopœia*, it

has no other power or sphere of action than are implied in the control of education and registration. Whether it would be wise to add altogether new powers and functions of another kind, and, if so, of what kind, is a question quite open to discussion; but, until some change is made in this respect, we cannot see of what use to the services it would be if they were represented on it as services; on what ground they could claim any such representation; how it could be effected; or what use they would make of it. As practitioners, they have unquestionably the same right to direct representation on the Council as other practitioners have; and, if the debated privilege of direct representation, for which this Association has long contended, be granted, army and navy medical officers will, of course, profit by it to the same extent as civil practitioners. The presence of Dr. Parkes is undoubtedly useful, as affording the Council information and guidance relating to army medical instruction; and it would, we think, be a graceful and proper thing that a member of the Naval Medical Service and one of the Poor-law Medical Service should be elected to the Council, to afford similar information. But we apprehend that their absence is due to the want of popular influence in the professional elections to the Council, and to the undue preference shown by the Crown to eminent men in "pure" practice and holding high university or collegiate positions. Of this undue preference, complaint may fairly be made; but we are disposed to believe that the remedy lies in the change to a more popular mode of election, and to direct representation, rather than to any further move in the direction of class-representation.

When we come to the British Medical Association, however, we are contemplating a body of a very different character—one having a wide popular basis, a representative constitution, and aims which comprehend all that interests medicine in its social, scientific, and ethical aspects. The governing body of the Association is based on the representation of all classes of its members. The members in Branches are represented in direct proportion to their numbers on the General Council and Committee of Council; and provision is also made for the representation of members of the Association not members of Branches. It is only necessary for a member of the Association to join his local Branch in order to attain at once to the fullest share of direct representation, not only in that Branch, but in the whole Association. In Ireland, however, our members have been slow to adopt the method of organisation in Branches, by which full representation in the governing body of the Association is secured. They have been content to be connected with the Association through the *JOURNAL* and the occasional visits of some of their members to the annual meetings. This slowness of our Irish members to organise, undoubtedly deprives them of some of the share of representative influence which they would otherwise have, and which lies ready at their hands if they choose to use it. The Committees of the Association have always been very ready to give attention to all subjects interesting to our members in Ireland; this letter gracefully and courteously recognises assistance rendered during the past year, and this readiness has enabled our Irish associates to call in the aid of the Association on public and parliamentary occasions. There is, however, no one but themselves to blame that they are not more largely and formally represented in the Council of the Association, and that they do not always speak with the collective voice which they would have if organised in Branches and represented by delegates on the Council and Committee of Council. It is only necessary for them to meet, say in Dublin, and form a Branch there, and subsequently to select other centres, and in each place to organise the existing members of the Association into local Branches, as has been already done at Cork (South of Ireland Branch), and as has been still more frequently done in the sister kingdom of Scotland.

The Poor-law Medical Service is very largely represented by existing officers of Branches and delegates to the Council, and might easily be

more so if it were desired. They have all settled habitations and local connection; they muster largely at every Branch meeting and annual meeting of the Association, and make their voices heard and respected. They may easily do the same in every part of the kingdom.

The case of the Army and Navy medical officers in active service is different, and it is a question whether it might not call for special treatment, if they desire it. They are a very special body, living wholly under a peculiar régime, and having in some respects very sharply defined interests. Moreover, they are nomadic, and local organisation is to them not easily attainable. In some localities, as in the Southern Branch, they muster strongly; and there they have at this moment a distinguished representative, an eminent officer of the Naval Medical Service, Inspector-General Smart, C.B., who is President of the Branch, and also a member of the Committee of Council. By the formation of Branches of the Association at Aldershot, the Curragh, Dublin, Chatham, Woolwich, etc., the same result might be attained as has proved very beneficial to the Naval Medical Service from the organisation at Portsmouth. The number of army and navy medical officers who are members of the Association is very considerable, and is steadily, and of late rapidly, increasing. It is a question for them to consider, whether they will not best serve their own interests by multiplying local Branches at stations where naval and military officers are numerous. These Branches will serve all the purposes of other Branches for social and scientific purposes; and the result of their scientific activity, being published in our columns, would no doubt be a valuable addition to the knowledge of the profession, while they would also, in virtue of their delegated officers of Branches, acquire a definite influence in the councils of the Association and the profession, such as is at present attained with difficulty and by the private energy of individuals of variously balanced judgment. If, on the other hand, the naval and military medical officers desired to form an United Service Branch in the Association, they would have to address a collective representation of some sort to the Committee of Council, who no doubt would endeavour to meet their wishes in some other way. We advert to this subject at some length, because it has already been brought before us from various sources. We believe, however, that the balance of advantage would probably be found in the formation of local Branches of the ordinary kind at the places where the services are strongly represented. At Woolwich, Chatham, Plymouth, the Curragh, Dublin, Aldershot, and other places, there are already more than enough of our military, naval, and civil members to form local nuclei, which may be easily increased by a little trouble in further recruiting; and in this we shall be happy to give assistance.

THE PUBLIC HEALTH BILL.

Rudis indigestaque moles. What hopes, what charms, lurked in consolidation of the public health statutes! It seemed too good to be true. But *sanitas sanitatum, omnia sanitas* remained; and so we hoped and were charmed. Did not the President of the Local Government Board, in a pleasant and plausible speech weeks ago, promise us, instead of the shoals and quicksands of the treacherous statutes which had for twenty-seven years more or less stranded or wrecked many goodly projects of sanitary improvement, a smoothly flowing broad stream, upon which we might sail in safety, and carry with us freights of health and comfort to every benighted district in the land? Alas! we awake; and lo! it is a dream. It is true we have not been without our warnings. To find a Government intent on consolidating (*sic*) the laws of public health, and in the very same session trying to put on the statute-book a separate Act for improving insanitary areas and districts and the dwellings of the poor, was a little trying to one's confidence and belief; but this was an inadvertence to be remedied, and we hoped. And now we have three hundred and thirty-three clauses in a Bill which is all clauses, with all our difficulties untouched, with all the defects of the

past without remedy, and passed by, apparently, without the slightest sense of their existence. It is true, there is some advantage in having only six statutes to wade through for the law, instead of six-and-twenty; but there all advantage ends. The instructions given to the draughtsman of the Bill appear to have been simply mechanical, and to have been carried out in a simply mechanical manner. Clauses entirely inoperative are pitchforked into the Bill without change of a word; incongruous and contradictory provisions are not attempted to be reconciled; omissions are not supplied; and excrescences are not removed. Sanitary authorities are not helped when striving faithfully to exercise their functions. Companies for the supply of gas and water are to be provoked to the direst hostility, as, unless protected by special Acts, their existence is ignored, and their property practically confiscated. Distinctions of the most objectionable character are still instituted between urban and sanitary authorities. There is no attempt at effective compulsion, and no appeal provided for either authorities or for ratepayers; while, where there is an attempt at control, it is of the most weak and impracticable character. There is no attempt at simplification of areas, at rectification of boundaries, or at unification of authority; or any apparent knowledge of the difficulties which practical men, whether officials or consultants, have found in carrying out the law.

In dealing with a subject so eminently important and confessedly so difficult as the detail by which sanitary reforms can with the least possible hardship to ratepayers be carried out in the country, it was to be expected that counsel would have been taken of those whose duty it was and is to carry public health laws into action. No trace of any such knowledge appears on the face of the Bill. Inequalities of rating, difficulties as to private improvements, works without the district of a local board, the provisional order system, nuisances arising in one district, but manifesting themselves in another—these, and many others which space does not allow us to particularise, remain unrecognised, and therefore untouched. However, it is something to have even a Bill in draught introduced into the House. We earnestly counsel delay. Let the measure remain for the session, to be amended and improved by careful consideration and widely taken counsel, to be passed in the next session. Crude legislation is more than ought else to be deprecated and avoided; it will throw back the cause of sanitary progress for the next ten years. Let us be clearly understood: we are not clamorous for further powers; we do not insist on heavily taxing the community; we deprecate too free an use of compulsory powers, even for the good of those for whom they are to be exercised; but this we do ask, that the light which experience has given us may be allowed to interpenetrate and chase away the darkness and doubt of the present Public Health Bill.

THE Medical Society of Lemberg has decided on holding a congress of Polish physicians and naturalists in that town in September.

THE name of John Pearson Bell, M.D., has been added to the Commission of the Peace for Hull.

DR. ALFRED MEADOWS has been elected a corresponding member of the Medical Society of St. Petersburg.

DR. VON LUSCHKA, Professor of Anatomy in Tübingen, died on March 1st. He enjoyed a high reputation as an anatomist; and is known as the discoverer of the coecygeal gland.

OUR readers will have doubtless noticed the notification in the newspapers that the spring assizes have been removed from Leweston Brighton. This step was rendered necessary in consequence of the occurrence of a number of fresh cases of typhoid fever. We are however informed, on the best authority, that this recrudescence of the malady, which has been so prevalent in Lewes, is checked, and that it is again subsiding.

A HUNGARIAN lady, Baroness Schuhaj, is reported to have died recently in Prague at the age of 118—having been born in 1757. Her eldest son was killed in 1809, at the battle of Wagram, where he was a staff-officer.

MR. RICHARD STAMPER of Malton has been accidentally poisoned by taking an overdose of chloral, which he had been in the habit of taking. Deaths from this cause have become rather frequent of late.

THE Medical Officers of Health in the counties of Northumberland, Cumberland, Durham, and Westmorland are forming an association for mutual counsel and assistance in the performance of duty, the reading of papers, and exhibitions of sanitary appliances, etc. The inaugural meeting is fixed to take place on the 3rd of April, at the Infirmary, Newcastle-on-Tyne. Dr. Henry Yeld, medical officer for Sunderland, and Mr. Henry A. Armstrong, medical officer of health, Grainger-ville, are doing the preliminary work of secretaries and organising.

THE amount of money spent by the Metropolitan Board of Works from January 1st, 1856, to March 25th, 1874, amounted to £6,067,228. This sum represents the total amount expended on new sewers, sanitary work, paving, and other expenses. The construction of 635 miles and 298 yards of new sewers, cost £1,731,474 11s.

THE Prince of Bavaria, whose sister married the Crown-Prince Rudolf of Austria, has, it is stated, adopted medicine as his profession. By all accounts he will be a very successful practitioner: for he has not only received a diploma, but he has within the last few days performed a most difficult operation at the Munich Ophthalmic Hospital.

THE PROPOSED ADULTERATION BILL.

AT the meeting of representatives of the Associated Municipal Corporations held in Westminster, the provisions of the Adulteration of Food and Drugs Bill were considered, and Sir Joseph Heron stated that there was a general opinion that, as the Bill would enable those who sold adulterated food to escape conviction, town councils might as well dismiss their analysts. The Artisans' Dwellings Bill was referred to, and many speakers expressed their approval of that measure.

QUALIFIED MIDWIVES.

MR. JOHN R. CAMPBELL describes the nursing system in vogue in Norway, and suggests the adoption of such a system in England. "Almost every Norwegian parish has its *Fjordemoder*, or professional nurse, a woman educated, as I understand, at a hospital, and who acts under the direction of the doctor of the district, being qualified to attend confinements (where in Norway a doctor is seldom thought necessary), to cup, bleed, etc. On the occasion of a slight contusion received through a fall a few summers ago, the doctor whom I consulted advised cupping, and this was done at my inn by the *Fjordemoder*. Her charge, I may mention, was 3d. 'a cup'. Would not such a class of women be extremely serviceable, especially among the poor, in our own country?" There is also a regularly organised system of instruction and supervision for midwives in Sweden and in Denmark.

THE JACKSONIAN ENDOWMENT AT CAMBRIDGE.

THE vacancy in the Jacksonian Professorship of Natural Philosophy at Cambridge, caused by the death of the late Professor Willis, has been the cause of some discussion in the Council of the Senate. It was thought that the time had arrived when the practice of this Professorship should be brought into closer conformity than heretofore with the general objects indicated in the terms of the foundation; and that the professorship should in future be affiliated to the Board of Natural Science Studies, as more in harmony with the subjects indicated in the will of the founder, as coming within the scope of the lectures. In the discussion on the report presented by the Council of the Senate, Professor Latham took occasion to remark that expressions in Mr. Jackson's will showed that that gentleman was evidently in advance of his time, both as to the mode of lecturing and as to the subjects to be taught in

the University. For instance, Mr. Jackson directs that the professor shall read publicly a course of lectures on anatomy, animal economy, chemistry, botany, agriculture, or the *materia medica* at large, with due and proper exhibitions of the subject to be read upon, or whose properties are to be explained or inquired into, together with proper dissections and analyses of the same according to their respective natures, etc., "so as to form a more certain practice than at present exists of the art of curing diseases, or preventing or making life more easy under them". Dr. Latham holds that these expressions point clearly to a professorship of Public Health or State Medicine; and observes that, although Mr. Jackson mentioned one particular disease—the gout—as an *opprobrium medicorum*, and wished the Jacksonian Lecturer to pay special attention to the history and treatment of that disorder, yet, had he lived in these days, he would probably have named typhoid fever as a pressing subject for investigation, together with the cognate subjects of town-drainage, elongated cesspools, etc. Dr. Latham went on to point out that, although the University had only this year established an examination on Public Health, yet students had no special opportunity of studying the subjects of that examination. He, therefore, strongly urged on the Council the consideration of the propriety of making the Jacksonian Professor a professor of Preventive Medicine, State Medicine, or Public Health; and read some of the regulations recently issued by the University for the examination in State Medicine, showing that almost the actual words of Mr. Jackson's will were used in describing some of the subjects of examination. We heartily endorse Dr. Latham's views and recommendations, which are entirely in accordance with our published views on the subject, and trust that the discretionary power of defining from time to time the several objects of the will, referred to by Professor Stokes, will eventuate in the establishment of lectures on sanitary science in connection with the Jacksonian Professorship advocated by the Master of St. Peter's and Professor Latham.

SANITARY CENSUS IN BIRMINGHAM.

IT appears, from a recent report to the Sanitary Committee of the Birmingham Town Council, that 70,000 houses in that borough have recently been inspected, in 20,000 of which the windows were so constructed as not to admit of their being opened at the top. It was also shown, that 24,000, or a third of those examined, are still dependent on the surface wells of the town, which are most of them polluted with sewage, for their water-supply; and 101 houses were found to be without water-supply of any kind. This kind of sanitary census must be infinitely useful to the sanitary authorities of the town, and might be taken very much with advantage in many other large towns.

HOSPITAL SUNDAY FUND.

WE are glad to see that the expectation which we expressed last week, that the unsatisfactory proceedings at the Mansion House on the 8th inst. would be as strongly condemned by the public as they have been by the profession, has been already realised. Another meeting, differing widely from the last, in the dignified and business-like character of its proceedings, was held under the presidency of the Lord Mayor on Tuesday. Many men of high standing and influence attended personally, or sent letters expressing their strong disapproval of Dr. Morell Mackenzie's resolutions. Several of these were members of the Hospital Sunday Council, who were desirous of retiring from it if these resolutions were to be carried into effect. Among the latter was Sir James Paget. The feeling of the meeting evidently was that it would be better that the whole scheme should fall to the ground than that such pernicious regulations should be enforced. Canon Miller, Canon Harvey, and several other influential clergymen reminded Dr. Morell Mackenzie and his followers that the fund must be collected before it could be distributed, and they declared that, unless the resolutions were reversed, they would never preach for it again. Sir Rutherford Alcock moved, and the Rev. T. J. Rowsell seconded, the following proposition:—"That the Council declines to act upon the resolutions passed

at the public meeting on the 8th inst., believing that those relating to the constitution of the Distribution Committee, and restricting its discretionary power, would, if carried into effect, prove adverse to the just and generally satisfactory administration of the fund." To that an amendment was proposed by Mr. R. Brudenell Carter, in these terms:—"That this Council, having been appointed by the annual public meeting held on the 4th of January last, to make arrangements for the collection and distribution of the Hospital Sunday Fund for the current year, declines to hold itself bound by or to accept otherwise than as recommendations worthy of being considered, the resolutions of any meeting held during its tenure of office." In the end, the amendment of Mr. Brudenell Carter was carried almost unanimously. It was then resolved, on the motion of the Rev. Dr. Kennedy, seconded by the Rev. H. R. Haweis, that, before any further action should be taken, the ministers of religion in the metropolis, with two members of each congregation, should be invited to a conference at the Mansion House on the subject. The meeting closed with a vote of thanks to the Lord Mayor for presiding.

ACCIDENT TO MR. W. D. HUSBAND.

WE regret to learn, that a severe accident happened, on the evening of Saturday last, to Mr. Husband of York, lately President of the General Council of the British Medical Association. Mr. Husband, it appears, was returning from a visit in the country, in a two-horse cab: when, in passing through a narrow portion of the road, the evening being dark, the vehicle came into contact with another vehicle. The driver was thrown from his box, but escaped without injury; the horses ran away, and Mr. Husband, who had been asleep, being awakened by the noise, and seeing no driver, opened the door and jumped out, in doing which he fell, striking his head on the ground. The result was, that he was severely cut about the head, and received considerable injury in one ankle. He was also rendered insensible for some time, and had some symptoms of cerebral congestion. Mr. Husband is, it is reported, progressing as favourably as can be expected, although it is probable that his injuries will confine him to his house for some time.

THE MARRIED HUTS AT WOOLWICH.

THE War Office certainly cannot be charged with undue precipitation (although it is open to the charge of singular hurry), in removing the inmates of the huts at Woolwich, in which zymotic disease of one kind or another has long been endemic. It is not the fault of the medical department that it has not been done long since. We stated many months ago, that the medical reports were decided as to these huts being unfit for human habitation. The War Office has chosen to ignore these representations, and in ultimately beating a hasty retreat to misrepresent their character. It would show how careless the conduct of the military authorities has been, if the whole series of medical reports on the subject, beginning from those of Deputy-Inspector General Barrow, were moved for and produced in the House of Commons. But we suppose it is exceedingly unlikely that Mr. Hardy would produce them; he certainly will not if he listen to some of his immediate personal advisers.

THE CASE OF MISS WOODS.

THE circumstances of this case having been the subject of much comment, it seems desirable that the following, which we believe to be an accurate and careful summary of the leading facts relating her detention, should be made known. Miss Woods was first sent to the asylum, in which she is now detained, on the 27th instant, under an order and medical certificates. The latter were not in substance satisfactory, and she was received into the asylum under Clause 11 of the Act 16 and 17 Victoria, c. 96, which provides that, "If after the reception of any lunatic, it appear that the order or medical certificate or (if more than one) both or either of the medical certificates upon which he was received, is or are in any respect incorrect or defective, such order or medical certificate or certificates may be amended by the person signing the same at any time within fourteen days next after the reception of such lunatic:

provided, nevertheless, that no such amendment shall have any force or effect unless the same shall receive the sanction of one or more of the Commissioners". One of the certificates, which was defective, not having been amended to the satisfaction of the Commissioners, this certificate became invalid, and the patient's discharge was the necessary consequence. Her friends, however, had the patient re-examined, as they had a perfect right to do, with the full assent of the Commissioners; and, as a result of the re-examination, she was upon the same day readmitted upon a new order and new certificates. The gentlemen who separately re-examined the patient are both thoroughly competent men; both are physicians to the Salisbury Infirmary, and their certificates are decided as to her being of unsound mind, and also a fit and proper person to be detained under care and treatment. Everything that has been done in this case has been in accordance with the ordinary usage, and with the provisions of the Lunacy Act. When all is said that can be said, and all is known that can be known, it seems probable that the result will be to show how minute and complete are the precautions with which the Act surrounds the person of unsound mind. The action of Miss Woods's friends in this matter has been guided by motives of humanity and justice, and has resulted in removing her from a scene of filth and privation, which it was believed made her life not worth a day's purchase, and has placed her under the protection of the law, in a place where mind and body will be alike cared for, and where, under the highest safeguards, she has the benefit of all that skill and care can provide to ameliorate her physical and mental condition.

THE LATE SIR RANALD MARTIN.

A COMMITTEE is being formed for the purpose of establishing a permanent form of memorial in honour of the late Sir Ranald Martin, K.C.B., F.R.S. The idea is that the memorial shall take the form of a prize in connection with the Army Medical School. A meeting to inaugurate the movement will take place on Thursday next (the 25th instant, at 4 o'clock) at Willis's Rooms, under the presidency of Sir Galbraith Logan.

ROYAL COLLEGE OF SURGEONS.

MR. JOHN HILTON, F.R.S., consulting surgeon to Guy's Hospital, having resigned his seat as a member of the Court of Examiners, to which he was elected in 1865, a special meeting of the Council was held on Wednesday, the 17th instant, to appoint his successor, when the choice of the Council, not unexpectedly, fell on Mr. John Cooper Forster, also of the same hospital, where he is surgeon and lecturer on surgery. Like his colleagues, Messrs. Savory, Holden, Marshall, and Holmes, he is a Fellow of the College by examination, but not at present a member of the Council, having lost his election by one vote in 1873.

MEDICAL SOCIETY OF LONDON.

THE 102nd Anniversary dinner of the Medical Society of London, was held on Monday the 8th instant. A large number of the Fellows and their friends were present. The visitors included the presidents of the Royal Medical and Chirurgical, the Pathological, the Hunterian, and the Pharmaceutical Societies; the master of the Apothecaries' Society; and Dr. Harvey, U.S.A. The president, Mr. Victor de Méric, in proposing the toast of the evening, "Prosperity to the Medical Society", adverted to its increasing numbers, and the lively discussions which had taken place during his year of office; and acknowledging the admirable way the secretaries had supported him, in the name of the Council, presented Mr. Braine, the retiring secretary, with a silver medal for special services. Dr. C. J. B. Williams, in returning thanks for the other learned societies, alluded to the ancient date of the Medical society, its popularity with the profession, and also to the freedom with which its discussions were carried on. The following were elected office-bearers for the ensuing session: *President*: C. H. F. Routh, M.D. *Vice-Presidents*: W. H. Broadbent, M.D.; H. Royes Bell, F.R.C.S.; F. W. Pavy, M.D.; C. F. Maundslor, F.R.C.S. *Treasurer*: John

Gay, F.R.C.S. *Librarian*: J. C. Thorowgood, M.D. *Secretaries in Ordinary*: C. Th. Williams, M.D., F.R.C.P.; Richard Davy, F.R.C.S. *Secretary for Foreign Correspondence*: William Cholmeley, M.D. *Orator*: Erasmus Wilson, F.R.S. *Council*: The Rev. David Bell, M.A., M.D. (Goole); Woodhouse Braine, F.R.C.S.; John Brunton, M.A., M.D.; Thomas Bryant, F.R.C.S.; R. Brudenell Carter, F.R.C.S.; Sir Henry Cooper, M.D. (Hull); R. Farquharson, M.D.; Joseph Fayrer, M.D., C.S.I.; F. J. Gant, F.R.C.S.; Clement Godson, M.D.; J. Hainworth, F.R.C.S.; T. Harvey Hill, Esq.; Wm. Mac Cormac, F.R.C.S.; Victor de Méric, F.R.C.S.; W. D. Napier, Esq.; J. H. Paul, M.D.; J. Russell Reynolds, M.D., F.R.S.; A. E. Sansom, M.D.; Leonard Sedgwick, M.D.; Alfred Wiltshire, M.D.

DANGERS OF FOOTBALL.

WE regret to announce the death of a promising student of St. George's Hospital, Mr. S. J. I. Branson, from injuries received at a football match. The deceased gentleman, who was aged 21, and was in the second year of his medical curriculum, was a member of the St. George's team, and, on Wednesday, the 10th instant, was playing at Battersea Park for his club against the Royal Naval School, Greenwich. Sublieutenant Bayly, of the latter side, was running and carrying the football, when deceased tried to stop him, and seized him near the knee. Deceased fell, and Mr. Bayly came down upon him, so that his knee struck deceased on the chest. Mr. Branson at once experienced great pain in the abdomen, and was conveyed home in a cab. He was shortly attended by Mr. T. P. Pick and other gentlemen: but peritonitis ensued next day, and proved fatal on Monday last. At an inquest held on Thursday evening by Mr. St. Clair Bedford, the above facts were elicited, and the jury returned a verdict of "Accidental Death".

THE LEVÉE.

THE following members of the medical profession were presented at the Queen's Levée last week:—Surgeon Richard W. Coppinger, M.D., R.N., Fleet-Surgeon Thomas Colan, M.D., R.N., Surgeon Edward L. Moss, M.D., R.N., and Staff-Surgeon Belgrave Ninnis, M.D., R.N., on appointment to the Arctic Expedition, by the Director-General of the Medical Department of the Navy; Dr. H. Dobell, by Sir George Burrows, Bart., M.D.; Deputy Surgeon-General Dr. J. Fayrer, C.S.I., President of the Medical Board at the India Office, by the Secretary of State; Surgeon John Lucas, Indian Army, by the Secretary of State; Surgeon-Major C. R. Mosse, M.D., on being made C.B., by the Adjutant-General; Deputy Inspector-General John D. Macdonald, M.D., R.N., on promotion, by the Director-General of the Medical Department of the Navy.

A WARNING TO NURSES.

IN the early part of this month, a woman was charged before the Campden magistrates, near Warwick, with attending a patient in the same clothes which she had worn when nursing a person suffering from scarlet fever, without having had them disinfected. The result of this act was that the defendant's second patient, the wife of a farmer, and her two children were attacked with scarlet fever; the mother's case soon proving fatal. The magistrates inflicted a fine of 20s. and costs; and, at the same time, expressed a hope that the greatest publicity would be given to the case and the sentence as a warning, to all persons engaged in attendance upon the sick. We gladly assist in publishing the particulars of the case, because the successful adoption of precautions against the spread of infectious diseases depends not a little upon the greater frequency of such prosecutions as these. They play an useful part in disseminating a more general knowledge of the importance of precautions against contagion.

CONSANGUINEOUS MARRIAGES.

MR. GEORGE H. DARWIN, in an exhaustive paper on the Marriages of First Cousins and their effects, sums up the result of his investigations as follows. 1. Consanguinity of parents is injurious to the offspring. 2. Where the children seem to escape, the injury may show itself in

the grandchildren. 3. In many isolated cases, and even groups of cases, no injurious result can be detected. 4. These unions influence idiocy and imbecility more than the forms of insanity acquired later in life. 5. The frequency of these unions in Scotland (although not so great as supposed) somewhat increases the amount of idiocy there. Mr. Darwin's paper was read before the members of the Statistical Society, and will be published *in extenso* in the forthcoming number of the Society's journal.

THE WEATHER AND THE DEATH-RATE IN BERLIN.

THE following remarks occur in the recently published statistical return of mortality for Berlin. The excess of mortality in January of this year, over that of the same months in 1873 and 1874, is to be in great part ascribed to the frequent and sudden changes in temperature. The change was, indeed, quite unusual in suddenness and in extent; for, on the 2nd and 3rd, we saw the thermometer rise from -10.6 to $+2.2$ Reaumur (8.15 to 36.9 Fahr.); and on the 20th and 21st from -9.9 to $+4.9$ (9.7 to 43.25 Fahr.); followed the next day by a fall to -0.2 (31.55 Fahr.); while the deaths increased on the 2nd by 13, and on the 20th and 21st by 15. Again, on the 8th, when the thermometer fell from $+0.8$ to -5.3 (32.18 to 22 Fahr.), there was an increase in the death-rate, especially from diphtheria, croup, and phthisis. With few exceptions, however, most of the deaths from consumption occur on warm moist days, with a south or south-west wind. On such days, the mortality from this cause is almost doubled. It is remarkable that January 26th, the day on which the greater number of deaths (87) occurred, has the same mean temperature (-0.6 R. = 30.65 Fahr.) as January 23rd, on which day the smallest number (48) was recorded. This may in some measure be explained by the fact that, on January 23rd, the thermometer rose from -2.8 to 0.8 (25.7 to 33.8 Fahr.); while, on the 26th, it fell from 0.6 to -2.1 (30.65 to 27.12 Fahr.). Thus the following rule may be laid down for winter, though not without exceptions, as regards Berlin; the mortality rises and falls in an inverse ratio with the thermometer. In February, the greatest mortality occurred on the 18th (91 deaths), on the 14th (84), and on the 24th (82). From the 17th to the 18th, there was a fall of temperature from -0.83 to -5.53 R. (33.8 to 19.5 Fahr.); from the 13th to the 14th, the fall was from -3.87 to -5.90 R. (23.3 to 18.7 Fahr.); and from the 23rd to the 24th, from -4.9 to 6.1 R. (21 to 18.3 Fahr.). The fall was greatest (-4.7 R.) between the 17th and 18th; and then the highest mortality occurred: while the lowest mortality of the three mentioned (82) took place in connection with the smallest amount of fall (-1.2). It would be interesting to carry out these researches with reference to individual diseases.

ETHER AND CHLOROFORM.

OUR Liverpool correspondent writes:—At the Royal Infirmary, on Tuesday last, the proceedings in the operating theatre were rendered more than usually interesting by the attendance of Dr. Fildes of Boston, United States, who, at the request of the surgical staff, demonstrated the American method of giving ether, instead of chloroform, as an anæsthetic. The operations, three in number, were the division of the tendo Achillis in both feet in a child, by Mr. Harrison; removal of a small adenoid tumour from the breast of a young woman by Mr. Hakes; and the removal of a diseased metatarsal bone from a boy about 8 years old by Mr. Banks. In each case, Dr. Fildes gave ether, using no other apparatus than a conical hollow sponge. Complete anæsthesia was produced in each case in from three to four minutes. Addressing the students and those assembled in the theatre, Dr. Fildes said: "That, although an American by birth, he had been educated in England and in Paris; had no prejudice either for or against chloroform, and had enjoyed ample opportunities of witnessing the use of both chloroform and ether. The latter he had given himself in thousands of cases; had seen it given in the hospitals of New York, Boston, and other towns in his own country, and had never seen or heard of a fatal result. He was greatly surprised on his

arrival here to find that English surgeons still adhered to the use of chloroform, which in America was almost proscribed. The great superiority of ether was its perfect safety. The operator commenced and completed his task without the smallest anxiety as to the effect of the anæsthetic; whereas, when chloroform was used, it was impossible, in spite of every precaution, to predict with certainty that the patient, although in comparatively good health, might not, before or after the operation was finished, be found a lifeless corpse. As to the mode of administration, no expensive or complicated apparatus was necessary; nothing, in his opinion, was more suitable than a hollow conical sponge. It should be given at once freely: a lavish use of ether at first proved a saving of material in the long run. Etherisation presents three definitely marked stages: first, that of muscular relaxation; second, tetanic convulsive action; third, complete surgical anæsthesia, indicated by stertor, or what he called the 'snoring stage'; and, unless this stage were fully reached, there was risk of partial failure, so far as full insensibility to pain was concerned. We think it probable that the clear and forcible way in which Dr. Fitch has put the matter before the profession here will lead at least to a renewed trial of ether as a substitute for chloroform. In reply to our inquiry as to its adoption in obstetric practice in America, Dr. Fitch informed us that the employment of anæsthesia in labour was, he thought, gradually dying out in the States, many of the leading obstetricians believing that not only did it produce a greater liability to puerperal hæmorrhage, but that, when flooding occurred, the helpless and unconscious state of the anæsthetised woman rendered her incapable of responding to appeals to second by her own volition attempts to cause uterine contraction. It is worthy of consideration, however, whether ether and chloroform, in their anæsthetic operation, are in all points precisely analogous during childbirth. In surgery, profound insensibility is indispensable; not so in all cases of labour; indeed, only so in exceptional cases. Partial etherisation either produces complete muscular relaxation or tetanic spasm, either of which conditions might unfavourably influence the course of parturition. Chloroform, on the other hand, may, by careful management, be so administered as to produce and sustain for hours sufficient insensibility to render a tedious painful labour much easier of endurance. Moreover, we believe that, whatever may be the explanation, the observation of British accoucheurs has satisfied them that the parturient woman enjoys special exemption from the fatal effects of chloroform; no fatal case having yet been recorded in this country, and, unless our memory fails us, Dr. Marion Sims has publicly stated that a similar immunity has been noticed amongst the parturient women in the United States. (*Brit med Journal*)

ANOTHER FORM OF INDECENCY.

UNDER the above heading, Mr. F. Lockhart Robertson writes to the *Glasgow Herald* to protest, "in the name of common decency, against the action of the Scottish National Association for the Repeal of the Contagious Diseases Acts, in sending by post bundles of unsavoury tracts and speeches on this most disgusting subject, which might readily fall into the hands of young persons, happily ignorant of the very meaning of the ugly words used. 'The Acts' (he says) 'may be good or bad (it is an open question, to be determined mainly by results); but surely, in seeking their repeal, some care should be taken to protect the innocence of those whose minds are yet unsullied by contact with such tainted themes.'"

SOCIETY FOR THE RELIEF OF THE WIDOWS AND ORPHANS OF MEDICAL MEN.

THE officers of this Society have issued the following appeal.

"The numerous appeals which are made from time to time to medical men on behalf of the widows and orphans of their deceased professional brethren, make us anxious to draw your attention to the advantages offered to medical practitioners residing within the London district and in Middlesex by the Society for the Relief of the Widows and Orphans of Medical Men. This Society, instituted in the year 1788, has now an accumulated capital amounting to more than £70,000; the interest

on which, together with the subscriptions of members and donations, is distributed in grants to those widows and orphans of members deceased who have been left unprovided for. At the present time, there are fifty-eight widows and twenty children receiving annual grants from the Society, which last year amounted to £2,930:10; and in this manner £89,761:3:6 have been distributed since the formation of the Society. The Secretary attends at the office, 53, Berners Street, Oxford Street, every Wednesday and Friday from 4 to 5 P.M.; and from him may be obtained copies of the laws, lists of members, and forms of proposal for membership. He will also give any information required." It is signed by George Burrows (President); James T. Ware, William Fuller, Richard Quain, M.D. (Treasurers); and Joseph B. Blackett (Secretary).

SCOTLAND.

THE University of Aberdeen has resolved to give one of its prizes for an essay on "The University Systems of Scotland and Germany, and their Comparative Advantages".

IN Aberdeen, there has recently been an epidemic, fortunately of no great severity, of small-pox; but is now disappearing. There have been in all 46 cases of the disease in the Aberdeen Small-pox Hospital, of whom 10 died, and 6 remain still under treatment.

THE Council of the Royal Society of Edinburgh have awarded the Neill Prize for the Triennial Period 1871-74 to Charles William Peach, Edinburgh, for his contributions to Scottish zoology and geology, and for his recent contributions to fossil botany.

PROSECUTION UNDER THE MEDICAL ACT.

THE case of Banzie v. Peebles came up before the High Court of Justiciary in Edinburgh last week, in which "Professor" Banzie appealed from a conviction for offence against the Medical Act, by calling himself a Doctor of Medicine, and thus implying that he was registered. It was shown that the appellant possessed the degree of M.D. of the University of Philadelphia, and it was stated by his counsel that this was "after due curriculum and examination". In his advertisement, however, there was no mention made that the degree was an American one. After hearing counsel on both sides, the decision of the judges was deferred.

WATER-SUPPLY OF EDINBURGH.

WITH regard to the new water-works scheme, an unexpected difficulty has, it is said, arisen in the construction of one of the reservoirs at Edgelaw, which forms an important part of the works. It is supposed that the original borings which seemed to indicate a solid foundation for the embankment at a reasonable depth must have struck upon boulders or some exceptional feature in the substratum; for, on further examination, a bed of running sand was discovered reaching to the depth of over a hundred feet. This position has, in consequence, been abandoned, and fresh borings are being made higher up the glen.

EDINBURGH ROYAL INFIRMARY.

THE Royal Infirmary Bill was set down for hearing on Tuesday, before a select committee of the House of Lords, consisting of the Duke of Bedford, Lord Thurloe, Lord Rosse, the Earl of Limerick, and Viscount Enfield. But when the committee assembled, it was announced by the agents of the promoters, that there would be no opposition. The Bill will, therefore, go before Lord Redesdale, the Chairman of Committees, and be passed as an unopposed measure.

EDINBURGH ROYAL MATERNITY HOSPITAL.

A GENERAL meeting of the subscribers to, and other supporters of, the Royal Maternity Hospital was held on Monday, the Lord Provost in the chair, at which the claims of the institution were very warmly advocated by the chairman, Dr. Matthews Duncan, and other speakers. It was reported that £2,300 had been collected, in addition to the £2,500

which was expected as the surplus of the money collected by the Simpson Memorial Committee, towards the erection of a suitable maternity building, adequate for the purposes of the Institution, and worthy of the city of Edinburgh; the building at present occupied being merely an ordinary three-storey house. The difficulty of raising sufficient money is doubtless, to a great extent, due to the number of charitable buildings at present in course of erection or in contemplation, and the consequent endless calls on the pockets of the charitable.

PROFESSOR GAIRDNER ON EXAMINATIONS.

IN his closing address at the Glasgow University Medical Society, Professor Gairdner took up the subject of examinations. He pointed out that pass examinations were useful for their effects upon the studies of the majority who pass, rather than as "mere measures of police" for those who are rejected. "The examination", he went on to say, "should not aim at finding out what a man *does not* know so much as the discovery of what he *does* know, and of *how* he knows it—the kind of knowledge and the reality of acquirement being of far more consequence than the mere amount or extent of knowledge". He went on to show that cramming would enable a man to pass an examination, but it would not endow him with the power to think and to know his profession thoroughly. "Education is not mere information", says Professor Gairdner, and the expression is neatly turned as well as apposite. A medical education at hospitals and colleges is designed to enable a man to work for himself in after life, is really a means towards his educating himself—not, as some suppose, that a certain point of saturation with information may be reached, upon which a man may trade all his life after. These views of Professor Gairdner deserve careful attention on the part of those who are immediately concerned in the education and examination of medical students. The high class examination having been now fairly tried and been found not to answer—the capacity to answer questions not being the best measure of a man's real knowledge—the views expressed by Professor Gairdner may be found to be seasonable as well as sound.

EPIDEMIC OF TYPHOID IN CROSSHILL, NEAR GLASGOW.

THE inhabitants of Crosshill, one of the best situated and beautiful suburbs of Glasgow, have been very considerably terrified of late by the outbreak of an epidemic of typhoid fever. The number of cases is variously estimated at 100 to 150; but, as they are mostly among families of the better class, the excitement is, perhaps, proportionally greater. There seems little reason to doubt that the epidemic has had its origin from infected milk. The supply of milk comes mainly from the neighbouring village of Eaglesham, where cases of typhoid fever have recently been. The man who supplies milk to the district is a most vigorous newspaper correspondent, and, of course, protests that the epidemic has some other origin. Dr. Littlejohn has been sent down by the Board of Supervision to report on the epidemic, and his statements will probably convey some trustworthy information.

IRELAND.

OWING to the late inclement weather, the deaths registered in Dublin for the past week from affections of the respiratory organs, not including phthisis, amounted to 71, of which 58 were due to bronchitis, being an increase of 16 as regards that disease over that of the preceding week.

FROM the report of Dr. Cameron (City Analyst) for the month of February, we find that during that period 9,400 lbs. of pork, 360 lbs. of mutton, 150 lbs. of veal, and 4,480 lbs. of fish were condemned in Dublin as being unfit for food. The fines inflicted amounted to £22; and a sausage-maker was mulcted in £20 for having in his possession a large quantity of diseased pork, evidently intended for human consumption.

MEDICAL CONTRACTS BY THE DUBLIN UNIONS.

ATTENTION has lately been drawn to this matter, by the fact that for the past year the average cost of medicines for each patient, for the North Dispensary Districts, has been six and a half times as much as for each patient in the South Dispensary Districts. The average cost per patient in the southern division has remained nearly the same during the past ten years, but in the northern portion it has nearly doubled; and, from these circumstances, the Local Government Board intend to have an inquiry instituted as regards the cost of medicines in both unions, to endeavour to ascertain whether there has been an undue expenditure of medicines in the north districts, or sufficient use of them in the south division. Why such an extreme difference should exist between the unions is incomprehensible; but the promised investigation may perhaps elucidate the mystery.

ROYAL DUBLIN SOCIETY.

At a meeting of the Royal Dublin Society, the following were appointed as committees for their respective subjects, viz., *Botany*: Thomas Fitzpatrick, M.D.; Benjamin G. Darley, M.B.; Humphrey Minchin, M.B.; Walter G. Smith, M.D.; Wm. R. McNab, M.D. *Fine Arts*: Evory Kennedy, M.B. *Natural History*: Philip Bevan, M.D.; John Barker, M.D.; Rev. Samuel Haughton, M.D.; Robert McDonnell, M.D.; A. Foot, M.D.; Alexander Macalister, M.D. *Library*: Fleetwood Churchill, M.D.; Edward P. Wright, M.D. *Science*: E. D. Mapother, M.D.; Robert McDonnell, M.D.; Charles A. Cameron, L.K.Q.C.P.; Humphrey Minchin, M.B.; Emerson J. Reynolds, M.D.

THE DUBLIN MAIN DRAINAGE.

A THIRD meeting of the ratepayers of Dublin was held last week, and resolutions were passed condemning the Dublin corporation for their mismanagement with regard to the matter. The proposed "rubble masonry" scheme was condemned, in spite of the protests of a Mr. Norwood, who is chairman of the Main Drainage Committee of the Dublin Corporation. Mr. Norwood caused no little amusement by declaring that rubble masonry set in lime mortar was quite as good for sewers as bricks set in Portland cement, and stated, amidst the laughter of the meeting, that the only reasons why stone and lime were not used in London was, because there were no stones in London, and that English lime is so very different from Irish, that sewage acts upon the former, but not on the latter. Mr. Norwood failed, however, to answer the question put by one of the ratepayers, Why bricks and cement were preferred originally, if stone and lime-mortar were as good? The meeting concluded by electing a committee, and directing it to proceed with a Bill in Parliament to transfer the main drainage power of the Dublin Corporation to a new Board, such as we mentioned last week. We regret that the Bill has miscarried before the Standing Orders Committee of the House of Lords, owing to an omission on the part of the Parliamentary agents to serve all the necessary notices.

SANITARY CONDITION OF DROGHEDA.

AT a meeting of the corporation of this town, held last week, several sanitary reports from the officers appointed under the late Act were brought under the notice of that body, which pointed out the fact that to the insanitary condition of the town was due the present prevalence of a virulent type of fever. The corporation have issued orders to have the various nuisances complained of removed; and it may confidently be expected that, according as the sanitary condition of Drogheda improves, so in proportion will diseases of a zymotic character diminish. The medical officer of the Drogheda Infirmary, Dr. Adrien, reports that fever is spreading to an alarming extent in various parts of this town. In addition to the insanitary condition, he attributes the extension of the disease to the custom of "wakes", and urges that the sanitary authorities shall have the provision of the recent Act carried out more strictly.

DISCUSSION AT THE PATHOLOGICAL SOCIETY.

THE following is a short programme of the argument which will be developed by Dr. Charlton Bastian at the forthcoming discussion on the Germ Theory of Disease; being a discussion of the relation of bacteria and allied organisms to the virulent inflammations and to the specific contagious fevers.

The analogy between zymotic processes and fermentations is one which has been long recognised, though the "Germ Theory of Disease" in its present form is a doctrine of modern growth. It has been based on the supposed resemblance between the two sets of processes. Contagia came to be considered as allied to, if not identical with, ferments; and hence, after the promulgation of the Vital or Germ Theory of Fermentation by M. Pasteur, which was founded upon the belief that all true ferments were bacteria, torulae, or allied organisms, it became an easy step to imagine, and even adopt the notion, that all contagia might also be similar low independent organisms. Recognising the vast importance of such a doctrine for medical science, the writer was induced to undertake a series of researches, in order to test the validity of Pasteur's underlying doctrine of fermentation. Its general acceptance would almost of necessity have entailed most important modifications in our notions as to the true pathology, and consequently as to the treatment of the most important diseases to which the human race is liable. As a result of these researches, the truth of Pasteur's exclusive theory has been challenged in favour of broader physico-chemical doctrines of fermentation, and the whole question is now (as the writer supposes), in the opinion of most impartial critics, to be regarded as still *sub judice*. In the interval, therefore, we may look into this truth of the germ theory of disease from an independent point of view. The principal foundations of this theory seem to be of a theoretical nature. It is contended, with a considerable show of reason, that the multiplication of contagium within the body of the infected person, is a process which can only be compared to organic growth and multiplication. There are, however, other means of accounting for the increase of contagium within the body, which will hereafter be more fully explained. In addition to the germ theory of disease in the most generally accepted sense of the term, there is a rival doctrine advocated by Dr. Beale, which will be briefly referred to.

Applicability of the Germ-Theory to Virulent Inflammations and their sequelae. (*Gonorrhoea, Purulent Ophthalmia, Diphtheria, Erysipelas, Hospital Gangrene, Pyæmia, Septicæmia, &c.*)—The notion that bacteria have a causal connection with the process of infection in these diseases having been stated and its origin explained, an opposite doctrine is then announced; viz., that, instead of being themselves the infectious agents, or "carriers of infection", bacteria and their allies, when met with in diseased fluids and tissues, are for the most part actual pathological products engendered within the body. There is in fact, the writer contends, a bacterial degeneration, which, though not so common and wide spread in its occurrence, and though a process involving phenomena of a different order, may claim to rank side by side with fatty degeneration.

The facts and arguments in favour of these respective views are then briefly summarised. It is true that some of the considerations advanced in support of the latter doctrine may be explained by the hypothesis, that all the tissues of man and higher animals are densely interpenetrated by undeveloped and indistinguishable germs of the lowest organisms. This hypothesis is held by Dr. Beale; but it may be met, and, so far as it appears to be an answer to the writer's doctrine, set aside by evidence of the most convincing nature. But the notion (1) that germs of bacteria and allied organisms pre-exist (in some obscure way) within the tissues; (2) the notion that they enter from without, and are habitually very numerously distributed throughout the tissues of the body; or (3) that they are very commonly engendered by a process of degeneration taking place within tissue elements—all seem equally opposed to the views of Professor Lister and inimical to the theoretical basis on which he has allowed his antiseptic system of treatment to rest, however admirable this system may be in itself.

Applicability of the Germ Theory to Artificial Tuberculosis, Syphilis, Typhoid, Typhus, Relapsing Fever, Cholera, Measles, Scarletina, Small-pox, and other Contagious Fevers.—Although no real boundary line exists between the diseases considered in this section and those referred to in the last, the adoption of some such division is a matter of convenience in regard to the present discussion. Many of the facts and considerations previously advanced in support of the writer's doctrine as to the relation of bacteria and allied organisms to the latter class of diseases, are also applicable in regard to the present series. No positive facts of much weight seem to be forthcoming in favour of the germ-theory as applied to contagious fevers. Although these affections have always been regarded as "blood-diseases", in only one of them does it

appear that independent living organisms are to be met with in the blood of affected individuals at any stage of the disease. There is, therefore, here a *prima facie* inherent weakness in the whole theory, which a more thorough examination tends rather to confirm than to dissipate. The facts and considerations which may be opposed to the existence of any causal relationship between bacteria and allied organisms and the specific contagious fevers are then briefly enumerated.

After some statements and explanations concerning the occurrence of organisms in the blood of patients with relapsing fever, and in connection with diseased tissues in ovine, small-pox, and typhoid fever, as revealed by the researches of Dr. Klein, the writer will make some brief concluding statements concerning (1) Pasteur's recent important modifications of his germ-theory of fermentation; (2) upon the degree of relationship existing between zymosis and fermentation; (3) and as to the probable mode of action of ferments and contagia.

MEDICAL BOOKS AND MEDICAL ADVERTISING.

THE following rather severe remarks are translated from the introduction to a review of an English medical work in a past number of one of the most serious and weighty of French medical journals, the *Gazette Médicale de Paris*. It has a very obvious and direct bearing upon the question which Mr. James Lane discussed in his recent address at the Harveian Society, and indicates the opinion of a critic who is removed from our way of looking at the subject. The opening paragraph of the review in question runs thus.

"For some time past, English literature has become enriched by a large number of medical works, of which the object is not always the advancement of science and the search after truth. Many of these works are nothing but touting for patients—a kind of costly but paying advertisement, which their authors allow themselves to put forth in order to attract the attention of the lay public. The English are more inclined than the French to this kind of publicity, which is above the means of the French practitioners, who are generally not by any means rich at the outset of their careers, whilst their English brethren are frequently more in want of patients than of means. Thus every day we receive from them a large number of books for criticism, which we take good care neither to read nor to analyse, and of which the first page sufficiently shows the idea which has inspired the composition of the book."

An abuse which has gone to the extent of exciting the attention of foreign critics is not unworthy of our own attention.

We believe, with Mr. Lane, that the practice of advertising medical books, avowedly written for medical readers, in lay newspapers, is responsible for a great many evils. It affords countenance to quacks; it facilitates a system by which young men with long purses can give themselves the gratification of costly, continuous, and unblamed advertisement, on a platform where they are side by side with eminent and distinguished men; it discourages modest, meritorious, and unwealthy labourers in the field of medicine; and it does not elevate the dignity of the profession. The more entirely every man who aims at professional success is taught to rely upon the estimation of his fellows, the more genuine his efforts and his achievements are likely to be. These, among other reasons, seem to us to support the suggestion that medical advertising in lay papers is a custom which is more honoured in the breach than in the observance, and is one which is sooner or later doomed to disappear from the list of authorised medical practices, in which, in this country, it has somewhat exceptionally found a place.

PRESCRIBING DRUGGISTS.

ON Wednesday (last week) an inquest was held at the County Petty Sessions House, Stratford-on-Avon, before T. B. Couchman, Esq., on the body of John Aubrey, labourer, aged 63, who died suddenly on the preceding Saturday. Elijah James said: I am a registered chemist. On Saturday last, the daughter of the deceased called upon me about eleven o'clock, and asked for some medicine for her father, who she said was unwell. She said that he had a bad cough, a pain in the chest, and difficulty in breathing, together with weakness. I made up a bottle of mixture, with directions, and recommended a little brandy occasionally. I did not think that he was in danger. I never saw the deceased from first to last, but knew him well. Mr. Bernard Rice, M.B., gave evidence to the effect that he saw the body of the deceased on Tuesday morning, and from appearances it was not over-nourished. He found no marks of violence, and he considered him a worn-out man. He attributed death to natural causes. There was nothing dangerous in the mixture given by Mr. James, and it could not have caused death. The Coroner then summed up, and the jury returned a verdict in

accordance with the medical testimony that the "Deceased died from natural causes". The coroner complimented Mr. James on his capacity, and observed that the country was greatly indebted to such a class of persons. He was a registered chemist, and qualified to give prescriptions, and remarked that such chemists as Mr. James were conferring a great benefit to people by their ministrations, especially to the poorer classes. The juryman concurred with the coroner in his views. If the case had turned out differently, the comment would probably have been different. Meantime, it would be satisfactory to know on what ground the coroner considers a registered chemist, whose studies and examinations are in no sense medical, but simply pharmaceutical, to be qualified to give prescriptions. The opinion generally entertained is precisely opposite to this.

The following case is very similar to that above related. An inquest was held at Rattlesden on Tuesday (last week), before G. A. Partridge, Esq., coroner, on the body of John Grimwood, labourer, aged 65, who died very suddenly on the previous Saturday morning. Hepziba Davey said: I am the daughter of John Grimwood. I lived in his house. Last Thursday, he was taken with pain in the bottom part of his throat. On Friday, he went to the chemist's at Stowmarket, and got a box of pills and some medicine. In the middle of the night, my father complained of pain in his throat, and asked for ginger-and-water. He had some, and then had some of the medicine. He also complained of pain in his left arm. About four o'clock, my father was better. I made my husband's breakfast, and father took three cups of tea with some gin in them. He sat over the fire till ten o'clock; he then complained of pain, and got up, and then he fell on the floor. I ran for my husband, who was at work a little way off, and before I got back father was dead. He has complained of liver-disease for some time; he has not had medicine of Mr. Leech for seven years. Mr. Henry Payne Leech, surgeon, said: I have made a *post mortem* examination, and found the heart rather fat, the walls of the right auricle extremely thin, so much so that they had given way, and the pericardium was filled with blood, which would cause instant death. He had organic disease of the heart from natural causes. Nothing that he could have taken would have produced the unmistakable cause of natural death which I find. William Thomas Elliott said: I am assistant to Mr. Gostling, chemist at Stowmarket. John Grimwood came to our shop and complained of headache and flatulency. I gave him a little bicarbonate of potash, tincture of calumba, and aromatic spirits of ammonia, and a little tincture of ginger, and bismuth pills with extract of gentian. The verdict was "Natural death".

A correspondent has asked us, in reference to one of these cases, what course must be adopted to proceed against a chemist and druggist for prescribing, and at whose expense the action must be brought. It would be useless to proceed under the Medical Act if the person did not pretend to be registered. The Society of Apothecaries, we believe, have the power of prosecution; but whether they would exercise it in all such cases, we do not know.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the office of the Association, 36, Great Queen Street, Lincoln's Inn Fields, London, on Thursday, the 15th day of April next, at two o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary*.

36, Great Queen Street, London, W.C., March 18th, 1875.

METROPOLITAN COUNTIES BRANCH.

A GENERAL Meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Friday, April 16th, at 8 P.M.; when the subject of Legislation for Habitual Drunkards will be discussed.

ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

BATH AND BRISTOL BRANCH.

THE Fifth Ordinary Meeting of the Session will be held at the Royal Hotel, College Green, Bristol, on Thursday evening, April 1st, at half-past seven o'clock; F. MASON, Esq., President.

Bristol.

EDMUND T. BOARD, *Hon. Sec.*

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.

THE first meeting of the above district for the present year will be held on Wednesday, March 31st, at Terry's Restaurant (opposite the South-Eastern Railway Station), Tunbridge Wells, at 3 o'clock P.M.; BLACKALL MARSACK, Esq., in the Chair.

Dinner will be provided at 5 P.M., charge 6s., exclusive of wine.

All members of the South-Eastern Branch are entitled to attend these meetings, and to introduce professional friends.

The following communications are expected.

1. Mr. Marsack: Supposed Case of Vegetable Poisoning; Two Cases of Malignant Pustule.

2. Dr. Johnson: Case of Locomotor Ataxy; Case of Thoracic Myalgia.

3. Mr. T. F. Sanger: On Malaria.

4. Mr. W. Wallis: Case of Poisoning by Oil of Tobacco.

5. Two papers by Mr. G. F. Hodgson, of Brighton, President of the Branch.

THOS. TROLLOPE, M.D., *Hon. Sec.*

35, Marina, St. Leonard's-on-Sea, March 16th, 1875.

STAFFORDSHIRE BRANCH: ORDINARY MEETING.

THE Second Ordinary Meeting of the Session was held at the London and North-Western Hotel, Stafford, on Thursday, February 25th, 1875; present, R. GARNER, Esq., President, in the chair, and sixteen members.

New Members.—The following members of the Association were elected members of the Branch. Mr. W. T. Pater, Dr. Cookson, and Mr. G. Reid of Stafford; Mr. G. A. Baddeley of Gnosall; Dr. A. B. Greatrex of Lawton; Mr. E. P. Hamilton of Leek; Dr. J. Grant of Longton; Mr. J. T. Hartill, and Mr. M. P. C. McCormac, of Willenhall.

Death of Mr. F. Turton.—It was proposed by Dr. Millington, seconded by Mr. J. T. Hartill, and resolved—"That a letter of condolence be written and sent to Mrs. Frederick Turton of Wolverhampton, sympathising with her upon the decease of her husband."

Communications.—1. Dr. MILLINGTON read a paper on Hospital Abuses and their Remedies.

2. Mr. VINCENT JACKSON showed a specimen and made some remarks upon the drug Jaborandi.

3. Mr. COTTERILL made some remarks upon a case of Chronic Rheumatic Arthritis of the right Hip-Joint. The patient was exhibited.

YORKSHIRE BRANCH: ORDINARY MEETING.

ON Wednesday, March 10th, a meeting of this Branch was held at the Infirmary, Huddersfield.

Papers.—The following papers were read.

1. Dr. Eastwood: On the Treatment of Habitual Drunkards. After some discussion, it was unanimously resolved, "That the Bill for the Management of Habitual Drunkards, brought before the House of Commons by the late Mr. Dalrymple, be the basis of any future action on this subject, with a modification of the fifteenth clause, and that the members of this Branch be requested to sign a petition in favour of this Bill, to be presented to the Houses of Parliament."

2. Dr. Heaton: On a Case of Poisoning treated by Belladonna.

3. Dr. Cameron: On Psychological Facts apt to be overlooked in the Treatment of Children.

4. Mr. Atkinson: On two cases of Surgical Injury of the Chest without External Wound.

5. Dr. Alexander made some remarks on the Therapeutical Value of Chloral. Mr. Ellerton related a case of Complicated Pregnancy with Miscarriage at six months.

Dinner.—After the meeting, twenty-six members dined together at the George Hotel.

QUEEN'S COLLEGE, BELFAST.—The triennial visitation of this College was held last week, the visitors, including Dr. Duncan, President of the College of Physicians, and Mr. Jolliffe Tufnell, President of the Royal College of Surgeons. From the President's statement it appears that the total number of students in attendance for the session 1874-5 was 384, of whom 211 were students in medicine. Altogether the report was a satisfactory one, and proves at all events that the institution is not losing ground in the opinion of unprejudiced persons. A memorial was submitted on behalf of the College Athletic Club, asking that a suitable ground might be secured for them, and which the President and visitors promised to use all efforts to obtain.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 12TH, 1875.

SIR WILLIAM JENNER, Bart., K.C.B., M.D., F.R.S., President, in the Chair.

Hypertrophy of the Lower Parts of the Face.—MR. R. BARWELL exhibited a patient suffering from this affection; and said that simple hypertrophy, arising without definite cause—such cause, for instance, as might call forth increased muscular action, stretching, friction, or compression of tissue—was a rare event; especially rare, when no alteration of texture, no induration, thickening, or other change accompanied the malady. He had, therefore, brought this case under the notice of the Society, as no similar case appeared to have been previously recorded. The man, who was aged 20, and a sawyer by trade, went to bed one night, rather less than five years ago, perfectly well, nothing being wrong with his features. On rising next morning, the lips and lower parts of his face were enormously increased in size. There was no pain, heat, or redness; but a considerable discharge from the nose. Even now, when he caught cold, the face enlarged. The history, short as it was, required some consideration—possibly amendment. He said, his face was bigger on that first day than now, and his mouth was then, as now, drawn on one side. Mr. Barwell thought that, as to this first sudden enlargement, the man was probably mistaken; the increase was certainly not inflammatory, and could hardly have been hypertrophy. The first appearance of a marked deformity would make a great impression, which would slowly decline; for instance, he had observed the mouth being on one side at first, but its present crooked position had ceased to attract his notice. Hence it was more than probable that the first change was less marked than he supposed, and also than it now was. At present, the face, beginning at the edge of the jaw, was enlarged as far back as the edge of the masseters; the broad part of this enlargement extended as high as the lower edge of the malar bones; from this point it rapidly narrowed itself upward to the side of the nose, and terminated at the inner corner of each eye. The chief deformation fell upon the lips, which were enormously developed and everted, and for additional space thrown into folds. They were not cracked nor indurated, but in texture perfectly normal. The cheeks also were very thick and bulging. The labial glands were not enlarged. The tongue, though its mucous membrane was fissured, was not increased; the bones of the face were normal. It was very difficult to assign any cause for this condition, whether the malady might have arisen from some affection of the vaso-motor nerves allowing arterial increase, whereby additional nutriment was supplied to, forced upon, the tissues; or whether the tissues taking on increased growth attracted to themselves a greater supply of blood, could not at this date of the affection be determined. One thing, however, was evident, that the area of the increased nutrition corresponded to the distribution of the facial artery. Hence, Mr. Barwell considered, the only treatment likely to prove beneficial was to tie both vessels on the ramus of the jaw; which operation he proposed to perform on the morrow at Charing Cross Hospital.

MR. HOLMES inquired what were Mr. Barwell's views of the pathology of the case, and what was the proposed treatment. MR. BARWELL was unable to state the exact pathology, because the action of the trophic nerves was unknown, whether the increased arterial supply was primary or secondary to other changes. If ligation of both facial arteries failed to benefit the patient, he should recollect that Mr. Bryant had said that the only mode of treatment was to dissect away the whole submucous tissue from the inner surface of the enlarged lips. MR. HOLMES thought it was a question whether the local swelling might not be diminished by local treatment, as by free incisions into the hypertrophied tissue, cutting away small pieces, and allowing the incisions to discharge freely; very much as was done for the chronic oedema following upon erysipelas in a limb, or for thickening of a bone when the periosteum was cut down upon and divided. The pulsations of the arteries were certainly increased in this case, and the effect of ligation of the vessels it would be interesting to observe; but he confessed that he should be disposed first to try the effects of free incisions. MR. EASTES had seen a case of the kind treated in Guy's Hospital by the excision of a strip of mucous membrane from the whole length of the inner surface of the lip, and by the bringing of the two edges of the wound together by sutures: an operation which resembled that done for entropion by oculists. The result was favourable. THE PRESIDENT asked if the affection were congenital. People often imagined

that their disfigurements had come on suddenly, whereas they had actually been in existence for a long time. Perhaps this patient had had an enlargement of the lips for years, and an inflammatory condition simply increased it on the night after which he first noticed it. It was certainly difficult to see how so large a growth could occur in a few hours.—MR. BARWELL had heard nothing of the history, except from the patient himself; he would endeavour to show the man again at a future date, whatever the effect of the operation might be.

Tinea Favosa.—DR. DUCKWORTH exhibited a boy, aged 8, whose scalp and body were affected by this disease. He had had the disorder for sixteen months, and, it was alleged, had been once cured of it for a short time. The disease was very typically represented in this case, the primrose-yellow cups being distinctly seen in parts. The scalp had a strong mousy odour. There was no history of contagion. The boy's parents, Irish people, occupied three rooms near the Mint. Several brothers and sisters were unaffected. The cat in the house was also said to be free from skin-disease. The microscope revealed the presence of abundant spores of *Achorion Schonleini*. Dr. Duckworth commented on the extreme rarity of tinea favosa in London; and stated that this was only the fourth or fifth case that he had seen in the last ten years. The boy was poorly nourished, and had enlarged cervical glands. It was proposed to treat the case by poulticing, and the subsequent use of sulphurous acid; epilation would also be practised. Cod-liver oil and steel were to be given internally.

THE PRESIDENT remarked that the disease was very apt to return, so that patients went the round of the hospitals. Thus six patients only might supply all the hospitals in London with occasional cases for years. He hoped Dr. Duckworth would bring the boy before the Society again when he was cured.—DR. DUCKWORTH had exhibited a case last session, which was apparently cured after being under treatment for some time.

Fatal Pleuropneumonia in a Person addicted to Excessive Use of Alcohol, Morphia, Cannabis Indica, and Bromide of Potassium.—DR. WHIPHAM brought forward a case in which pleuropneumonia, though limited to a small portion of one lung, proved fatal in a patient aged 55, who had been accustomed for nearly twenty years to large daily doses of morphia; who had also taken cannabis indica in excessive doses; and who latterly had been very intemperate in his use of alcohol. The origin of the opium-eating was a pain, real or imaginary, in the rectum, which had attacked him about twenty years ago, from which he had been free until his father died of cancer in that region. He was a person always fond of "physicking himself". Opium in the form of laudanum was prescribed by a surgeon, as an injection *per rectum* in half-drachm doses, to relieve this supposed pain. This dose, though efficacious for a time, gradually lost its effect; and was gradually increased, until the quantity amounted, in ten years, to an ounce of the watery extract of opium in the course of a week. He then tried total abstinence from the drug, which was followed by nasal catarrh, purging, vomiting, and such utter depression, that his life was almost despaired of. After four months abstinence, he began again, and eventually took to morphia as being less bulky. When he first came under observation, he was in the habit of injecting two or three grains of morphia *per rectum*, repeating this dose, at intervals of fifteen minutes, two or three times, until he could "recover confidence in himself". He was advised to try to reduce the quantity gradually. When the daily quantity, however, was less than six grains, the former symptoms, *e.g.*, vomiting, purging, etc., manifested themselves, and he immediately increased the dose. At the same time, chloral hydrate was prescribed as an injection, with a view of diminishing the morphia. So far from this being the case, however, the only result was, that he took it ever after in addition to the morphia. Some six or seven years previously to his death, he tried large doses of cannabis indica, from which, owing to its failure in relieving his pain, he eventually abstained. Bromide of potassium he injected in scruple doses *per rectum* until six months before his fatal illness. During the last four or five years of his life, he became addicted to the abuse of alcohol, and in consequence suffered repeated attacks of dyspepsia. In the beginning of December 1874, he was attacked with pleuropneumonia of the lower part of the right lung; and, in the treatment of this disease, injections *per rectum* of two grains of morphia were at first productive of good results, but eventually the drug failed in its stimulating properties, and the patient sank after four days' illness. From subsequent inquiries, it appeared that the regular dose of morphia was one scruple in twenty-four hours, in addition to two bottles of sherry, brandy, and champagne, chloral hydrate in fifteen-grain doses frequently, and occasionally twenty grains of bromide of potassium. The points of interest in the case were—1. That a person could tolerate such large doses of these drugs, and at the same time suffer so slightly from their deleterious effects; 2. The catarrh, vomiting, and purging, which always attended any attempt

to reduce the quantity of morphia; 3. The marked benefit which resulted from morphia injections during his fatal illness.

In answer to queries, Dr. WHIPHAM said that no *post mortem* examination was allowed; that the jaundice with which the last illness was ushered in was temporary; that the patient gave himself the chloral, using it and morphia together; that the source of the pain in the rectum was not discovered after death, because no examination was permitted. It was suggested by a member that the man was a hypochondriac, and that he had no real pain.—The PRESIDENT asked if it were not a fact, that hypochondriacs did suffer pain; at any rate, they looked ill, and would submit to any violent treatment to diminish their sufferings. In his experience, opium lately was not so commonly used as chloral by the general public; some people took the latter drug night after night for weeks, months, years even, without thinking they were doing themselves any harm.—Dr. WHIPHAM said that his patient took drachm-doses by the rectum twice or three times daily.—Dr. DUCKWORTH remarked that the quantity said by the patient to have been swallowed and that admitted by the chemist to have been supplied was in this case the same. Sir Robert Christison had said that most of those people who took drugs secretly would tell lies to any amount; they did not, perhaps, mean to deceive, but would say they only took a few grains, whereas they were swallowing drachm-doses.—Dr. SOUTHEY observed that they would even come to the physician, pay their guineas, know full well from what they were suffering, and yet gravely ask advice. It was a species of insanity.

Acute Necrosis of Ulna: Removal of the entire Shaft of the Bone.—Mr. BARWELL read notes of this case. The patient, a girl aged 7, was brought to him by Mr. Cope of Croydon, who had attended her for fracture of the ulna. At the time he was called in, considerable inflammation had already commenced; but the case did well for three weeks, when the child again fell, striking her forearm severely. Inflammation of phlegmonous character, with tendency to abscess, and much pyrexia, set in. Six weeks after the primary injury, Mr. Barwell was consulted, and found considerable deep swelling and pink patches of discoloration along the subcutaneous ridge of the ulna. The limb was hot and painful, especially on movement. The temperature in the mouth was 101.2 deg. Acute necrosis was diagnosed, and an incision was made down to the bone through the middle third of the ulna. No pus was found beneath the periosteum, though a little existed in the soft parts of the limb. Some smart bleeding was easily restrained by pressure. The wound filled gradually, with the exception of four sinus mouths, and in five weeks the bone could be felt through these sinuses necrosed; while deep bony enlargement showed that new periosteal bone had been formed. A week later, the former line of incision was reopened, and the dead ulna, almost surrounded by new bone, exposed. Mr. Barwell was anxious to remove the dead, with as little injury to the new, parts as possible. Having therefore separated them, as far as could be done, with a blunt periosteal chisel, he succeeded in drawing out the shaft (which was exhibited to the meeting) lengthwise, leaving the epiphyses and the new bone connecting them entire. The Esmarch bandage having been used, scarcely half an ounce of blood was lost. The case went on perfectly well. Two months after the date of operation, Mr. Barwell saw the patient, and found the wound quite healed, the hand and arm perfect in form and in movements, though these were somewhat restrained. Three months later, Mr. Cope wrote—"The case has gone on without a bad symptom; there is perfect use of both elbow, wrist, and hand." Mr. Barwell remarked that he thought the name acute necrosis more in accordance with the course of the disease than acute periostitis. He spoke of the frequent absence of pus within the periosteum until a later period of the malady, and stated that in all cases early incision was imperative; but, as some difficulty existed in recognising the earliest symptoms of the malady, these were—age of patient, pyrexia, deep-seated and severe pain, uniform, deep, and doughy swelling, red patches (not dusky), mottled, on a normally coloured ground, both lying over the painful bone. If the surgeon waited until the swelling was nearer the surface, and pitted, and until the red patches ran together, and became dusky and glazed, he waited too long.

Mr. CALLENDER inquired if the injury caused fracture of the ulna, and if it were diagnosed as such.—Mr. BARWELL could only upon that point say what Mr. Cope had told him.—Dr. JOHN HARLEY observed that there had apparently been considerable absorption of the necrosed bone. Was it real or only apparent absorption? Was there any opening before the operation performed by Mr. Barwell? or was the absorption the result of that operation? Was all the bone which came away at the operation then exhibited?—Mr. BARWELL said that, when he went to operate the second time, he found four large sinus mouths; doubtless, some of the bone had disintegrated and come away through these channels; yet some of the bone was still perfect in shape, and

he could not imagine any surgeon leaving the dead bone unremoved, in the hope that it might become discharged of itself or absorbed.—Mr. HEATH presumed that it might be taken that there was no fracture. It was a simple case of acute necrosis set up by the original injury. Unless there had been suppuration beneath the periosteum, by which nutriment was cut off from the bone, he was at a loss to understand how such extensive necrosis could have occurred.—Mr. BARWELL said that, after the child had its fall in May, the symptoms thereby produced after a time diminished, and she was allowed to run about. She fell again on June 8th; the acute necrosis would seem to have then commenced, and the incision was made on the 26th, eighteen days afterwards, when no pus was found beneath the periosteum. It was a moot point if pus ever formed so rapidly in that situation.—Mr. CALLENDER said it was by no means an uncommon occurrence to find a child sustain an injury to a limb, and things then remain quiescent. A second accident occurred, and then followed acute necrosis of the shaft of the bone. It seemed that the first accident had led to some interference with the nutrition of the bone. Thus, if it caused damage to the nutrient artery, and occluded it, the vessels of the periosteum would then carry a larger quantity of blood to the bone, and the excessive vascularity would cause them to take on acute inflammation readily upon the occurrence of a second accident.—Mr. HEATH would like to know how Mr. Calender diagnosed plugging of the nutrient artery in a bone.—Mr. CALLENDER stated that, at a *post mortem* examination where necrosis had occurred, the nutrient artery was often found filled with old clot. Of course, it was difficult, when necrosis had occurred in the surrounding textures, to state exactly that occlusion of the artery had first taken place, although, as the clot sometimes seemed to be of old-standing, he thought he was right in surmising that change first occurred there. At any rate, he threw it out as a suggestion, and as a reasonable explanation of occurrences which he had witnessed.

PATHOLOGICAL SOCIETY OF LONDON.

MARCH 16TH, 1875.

GEORGE D. POLLOCK, F.R.C.S., President, in the Chair.

Disease of the Heart.—The Report of the Morbid Growths Committee on Dr. BURNEY YEO's case of disease of the heart was read. After describing the naked eye characters of the morbid changes, which agreed in the main with those given by the exhibitor, the reporters added that they found the endocardium unaffected, while the growth extended deeply into the myocardium, without distinct demarcation. There was no obvious degeneration of the mass. No other growth was found in the heart. From the microscopic examination, they concluded that there were (1) hypertrophy of the connective tissues, (2) an accumulation of embryonic cell-growth, (3) atrophy and absorption of the muscular substance. The new growth, they opined, was of syphilitic nature, of recent and rapid growth. There was no degeneration in the structure.

Skin-Disease in an Infant: Disease of the Nervous System.—Mr. J. HUTCHINSON exhibited an infant, the subject of skin-disease in association with disease of the nervous system. The child was the sixth of a perfectly healthy family, and was itself born healthy. The weather was cold; and the child was one day left exposed for some time; after which it had bronchitis and convulsions, which lasted for hours at a time. The skin became inflamed; there were vesicles, and ultimately the skin peeled for several weeks afterwards, and scabs were left, of which there were scars remaining. Beyond the scars, the rest was the mother's statement. There were also dark stains, which did not all mark the seat of a scar. The right eye became diseased, and was excised at the Royal Ophthalmic Hospital. On examination, it was found that the eye was not the subject of malignant disease. There was defective vision of the remaining eye. The child was six months old when first seen by Mr. Hutchinson. It made steady improvement for eighteen months without specific treatment. Its development was defective; it could neither stand nor talk; its hands were bent inwards; and its dentition was imperfect. The head was small, and the anterior fontanelle was completely closed. Mr. Hutchinson had seen no similar case; though he had seen two cases bearing some resemblance to this, which followed exposure to great cold. He thought the history of convulsions important. The face and head had completely escaped, as also the palms of the hands and feet. The stains did not follow any nerve-tracks, and the skin of them was quite supple. The left side throughout was worse than the right.—The PRESIDENT suggested that Mr. Croft should read notes of a case of his before the discussion commenced.—Mr. CROFT said that, on November 5th, 1872, he had exhibited before the Society a piece of integument removed from the left side of a child. On the surface, there were vesicles small and fine, from a one-

twelfth to one-fourth of an inch in diameter. On the deeper part was an old navoid growth embedded in fat. The child, then eight years of age, presented this oval patch of vesicles on her side, with a lump under it, which, when squeezed, made the child sick and faint. From August to October 1872, the child was under care without benefit; he therefore excised the whole mass. There were still vesicles on the scar and in its neighbourhood. They returned four months after the operation. The pain and tenderness, with sickness and fainting on manipulation, still remained. He thought it a neural affection allied to herpes, possibly chronic herpes. Probably the root of the spinal nerve was affected.—Dr. MURCHISON said that, in reference to the association betwixt exposure to cold and development of pigment in Mr. Hutchinson's case, he could recall a case of a gentleman who was exposed to a severe snow-storm, in which there was an abnormal development of pigment in the skin of the side of the face; the hairs, however, becoming white. This change set in a few days only after the exposure. There was also some atrophy of that side of the face. The pigment went round to the other side. There was no paralysis.

Intestinal Obstruction.—Mr. MAHOMED brought forward a case of intestinal obstruction which appeared to be worthy of record from the extreme rarity of its cause. T. C., aged 18, was admitted into St. Mary's Hospital under the care of Dr. S. Eveking, on March 5th, 1875, with well marked symptoms of ileus. Eight days before his death, he ate a meal of badly cooked potatoes, which was followed by vomiting and pain in the abdomen; the pain was not extremely severe, nor was it well localised. After six days' continuous vomiting, the matter brought up was distinctly fecal. His abdomen became tender and tympanitic. He had no action of the bowels, nor did he pass blood or bloody mucus up to the time of his death. No tumour could be felt in the abdomen while he was in the hospital. There was no localised, and but little general, peritonitis. He did not lie on his back, nor were his legs flexed. On the day of his death, coils of the distended small intestine were distinctly perceptible both to sight and touch, through the abdominal parietes. His temperature was never raised, but was usually below normal, falling as low as 97 deg. His pulse was not small, rapid, and contracted, like that of peritonitis; although rather quiet, it was fairly full and soft. At the time of his illness, he was suffering from a hard chancre, which he had had for several weeks. He had condylomata about the anus, indurated glands in the groin, and livid maculae on the skin. He died from exhaustion on the eighth day of his illness. He is said never to have suffered in a similar manner before, or to have had any trouble with his bowels. At the necropsy, the small intestines were found enormously distended with flatus and fluid fecal matter. A fibrous band was seen extending from the middle of the abdominal wall, midway between the pubes and umbilicus, backwards towards the right iliac fossa, carrying out with it, from the wall of the abdomen, a triangular fold of peritoneum. On tracing this cord towards its visceral termination, it was found to pass amidst the distended coils of intestine to the lower part of the ileum, where it had formed a noose, encircling a loop of ileum thirty-three inches in length; it passed one and a half times round the gut at the point of constriction, and was then found to extend into the mesentery of the ileum, about three feet from the ileo-caecal valve. On tracing the fibrous cord between the peritoneal layers of the mesentery, it was discovered to terminate in a large branch, apparently the ileo-colic of the superior mesenteric artery. On following out the fibrous cord that passed across the abdominal cavity towards its parietal termination, it was found, at the apex of the triangular fold of peritoneum carried out from the abdominal wall, to divide into two branches; one ascended to the umbilicus, accompanying the hypogastric artery of the right side; the other branch descended towards the bladder, and was terminated in the left superior vesical artery. It was thus proved to have been an abnormal hypogastric artery in the fetus, taking origin from a branch of the superior mesenteric, and sending a branch to the upper part of the bladder, to correspond with the usual distribution of the hypogastric and sub-vesical vessels. An attempt to inject the obliterated vessel from the branch of the superior mesenteric, succeeded to a certain extent. That part of the vessel which ran in the mesentery, but beyond the bowel, where it appeared as a fibrous cord hanging loosely across the abdominal cavity, was impervious. The cord was surrounded by a sheath of peritoneum. The intestines were obstructed at the point where the cord reached the mesentery. Above this point they were greatly distended, and below it they were contracted and pale. There was no strangulation of the gut at the point of obstruction, nor was there any appearance of recent peritonitis, with the exception of a little organised lymph at the point of constriction, both on the gut and on the mesentery corresponding to the lower end of the loop of intestine. The peritoneal surface of the distended gut was of a dark, dull colour, and the peritoneum was much injected, but there was no effusion of recent lymph. The mucous coat was deeply con-

gested. Peyer's patches were much congested, while the solitary glands were enlarged and very distinctly visible. Immediately below the point of constriction was a small diverticulum, about one and a half inches in length, possibly the remains of the vitelline duct. The lungs were much compressed; the upper lobe of the right was congested and carnified. The pericardium was firmly adherent to the whole of the surface of the heart. There were signs of old peritonitis on the liver; patches of puckered, organised lymph on its capsule. The spleen and kidneys were healthy.—Mr. SPENCER WELLS asked if the urine had been examined and biliary acids found in it. He remembered a case where a quantity of bile in the urine was the first symptom of an obstruction. In a case which Mr. Thornton was about to bring forward, the person died from obstruction to the bowels from a coil of small intestine adhering to the abdominal walls. Perhaps Dr. Murchison could tell the Society something as to the connection betwixt bile in the urine and bowel obstruction.—Dr. MURCHISON said that, neither by reading nor observation, was he familiar with what Mr. Wells spoke of. Was it bile acid or bile pigment in the urine? or some discoloration produced by the addition of nitric acid and boiling.—Mr. WELLS said there was a play of colour with nitric acid. There was jaundice, but no liver-disease.—Dr. MURCHISON asked if Mr. Wells intended to suggest that jaundice was a symptom of obstruction of the bowels.—Mr. WELLS replied that that was the point of his remarks, and that he asked for information.—Mr. MAUNDER suggested that it might be desirable to test the urine in strangulated hernia.—Mr. HULKE had noticed two cases of ileus in which there was no bile in the urine, at least to the eye.—Mr. HUTCHINSON said that, in these cases, the vomiting did not allow fluids to enter the system, which might have something to do with the matter.—Mr. JOHN WOOD inquired as to the condition of the hypogastric arteries, saying that the omphalo-mesenteric duct often remained, giving off anastomosing branches.—The case was referred to the Morbid Growths Committee.

Molluscum Fibrosum.—The PRESIDENT spoke of his case of molluscum fibrosum, which had, by some accident, been called molluscum contagiosum in one report. He said that, as well as hypertrophy of the skin, there was some albuminoid growth under the skin. The growth was altogether very vascular. The operation, unfortunately, was not successful, and the patient sank in a week.

Mixed Tumour of the Wrist.—Mr. BARWELL showed a case of mixed tumour of the wrist. It came from a man aged 56, who was in good general health. It had long existed, and was about the size of a pea. At last, there was some ulceration, and it became painful on pressure, so that the patient gave up work with that hand, in consequence of pain occasioned by accidental blows. It increased in size. It was movable on its base, which was the annular ligament, and its nodules were movable in each other. The tumour was excised, and found to consist of bony particles amidst a cartilaginous structure; the stroma consisted of spindle-shaped cells. On trying to get a good flap from the integument over the tumour, he found it so implicated that he abandoned it. The case did well.—Referred to Morbid Growths Committee.

Tumour of the Shoulder.—Mr. BARWELL showed a tumour from a boy aged 10, who had a fall on his elbow, after which the shoulder swelled. It grew so fast that excision was required. The mass was sarcomatous, with cells of very varying sizes; there was much fatty degeneration in the new growth. Cancer was hereditary in this family. The disease returned in the coracoid process.

Tumour of the Scapula.—Mr. JOHN WOOD showed a tumour of the scapula, taken, three weeks ago, from a man aged 24. The left scapula had on it a large growth of five months' duration, which extended on both sides, and caused the bone to protrude posteriorly. At the operation, ether was given, and even then there was much depression. Mr. Wood commenced by an incision under the spine of the scapula, so as to feel the growth, as to what it was. The whole glenoid cavity was involved. He then made the incision T-shaped, and, dissecting down, lifted up the scapula, and found the subscapularis and serratus magnus muscle implicated. There was considerable hæmorrhage; the cut surfaces were therefore drenched with a solution of chloride of zinc. All went well; much of the wound healing by first intention. Only two apertures remained, and there was a drainage tube through them. There was no return of the disease.

Fibro-fatty Tumour of the Zygomatic Fossa.—Mr. JOHN WOOD showed a case of fibro-fatty tumour from the zygomatic fossa, from a boy aged 12. The tumour pushed the lower jaw inwards, and the upper jaw outwards. It had been noticed for five years, and vainly subjected to various measures. He made an incision at the temple and another in the mouth, so that the fingers met. There was considerable adhesion at the zygomatic arch; and the tumour had to be twisted off. He passed a drainage-tube through the two incisions, and the case had done well. He was using pressure to the distorted zygomatic arch.

There were some cells in the tumour like polypus cells.—Mr. MAUNDER had seen two cases where polypus growths had passed into the zygomatic fossa.—Mr. WOOD asked if these tumours had been examined microscopically.—Mr. MAUNDER replied that they had been; they were fibrous.—The PRESIDENT asked Mr. Wood if much blood was lost in the removal of the scapula. He had compressed the subclavian in two such cases, and this had considerably diminished the loss of blood.—Mr. WOOD replied the loss was not great.—Both cases were referred to the Morbid Growths Committee.

Ovarian Cyst with Papillomatous Growths.—Mr. KNOWSLEY THORSTON exhibited an ovarian cyst with papillomatous growths in its interior. The tumour was tapped in July last, but only grew the faster for it. It was removed by Mr. Wells. There were no adhesions, and the ovary could have been detached and left, if desirable. It was an unilocular mass covered with a cauliflower-growth in its interior. It was covered externally by a capsule formed of thin layers of the broad ligament. In structure, the cyst-wall consisted of connective tissue, with round and fusiform cells. Though apparently an extraovarian cyst, it was really an enlarged Graafian follicle. A second single cyst was described, also a single Graafian follicle. Unilocular cysts were often cured by tapping. Though their growth was slow, they resembled malignant growths.—Mr. SPENCER WELLS remarked that careful microscopical observation of ovarian fluid often gave good indications as to the nature of the disease. Not only did it often indicate ovariectomy without delay, but, if the fluid escaped into the abdomen, secondary malignant disease might follow.

Secret Preparations.—The Council of the Society have decided, "That, inasmuch as it is contrary to propriety and opposed to the advancement of science, that secrecy should be observed with regard to the mode of preparation of any specimen brought before the Society. The Council resolve that Dr. Hoggan's communication on melanotic sarcoma in the cod, and specimens from a case of general cancer, which were illustrated by specimens, the mode of preparation of which he declined to explain to the Society, be not admitted to the *Transactions*."

CORRESPONDENCE.

THE CONTAGIOUS DISEASES ACTS.

SIR,—It is difficult for a single combatant to meet at one time three opponents, each more practised and accomplished than himself in the use of their weapons, which is the case in the present instance; in which I have to reply at the same time to Dr. Parkes, Mr. Lawson, and Mr. Ffolliott. I must simply do my best.

First, to take Mr. Ffolliott's letter; I have again to complain of small numbers, a picked regiment, and figures that do not admit of being checked; but, as he sees no unfairness in this, I will accept his figures, though the necessity for some means of checking unofficial numbers is again shown by Dr. Parkes's acknowledgment in his last letter, of "a slight misprint" of 54 for 44 in his previous letters. But, assuming the correctness of Mr. Ffolliott's figures, they are as follows. His regiment of 573 men was for seven months in Aldershot, a protected place, and had 4 cases of primary syphilis. It was 655 strong, and for twelve months in Colchester, also a protected place, and had 9 cases. Now, when the smaller strength and shorter period at Aldershot are made to correspond with the strength and time at Colchester, the number of cases rises from 4 to 7.8; so that we have—

Aldershot (protected)	7.8 cases
Colchester (protected)	19 cases

Or much more than double. But, if Colchester had been unprotected, it would immediately have been said—"See: on removal to an unprotected station, the amount of disease was at once much more than doubled." In fact, it is upon a smaller difference than this that Dr. Parkes has based his strong expressions in his letter to the JOURNAL of February 20th last, for the amount of primary syphilis in unprotected Parkhurst is only just double (instead of being much more than double) the amount in protected Portsmouth; and upon this difference, he writes as follows: "Can, then, anyone doubt that the unlucky 106th, by being sent to the unprotected station, has had, in proportion to its strength, more than two cases of syphilis to one case in the fortunate regiment in the protected station. . . . If figures can prove anything, they prove that the Acts have greatly lessened disease." As, however, Aldershot and Colchester are both protected, no notice whatever is taken by Mr. Ffolliott of this important difference in the amount of disease which furnishes such a text for Dr. Parkes about an unprotected place.

But his regiment afterwards removed to Dublin, which is unprotected,

and, being there for six months and a half, and 534 strong, there were 35 cases of primary syphilis. When the strength and time are again made to correspond with Colchester, the number rises to 79 cases; and Mr. Ffolliott "has no doubt what will be the opinion of every person whose mind is not biased by a foregone conclusion": that is to say, much more than twice the amount of disease in one protected town compared with another is of no consequence, and is not even alluded to, though barely twice the amount in an unprotected town is the ground for Dr. Parkes's strong expressions about Parkhurst. Much more, then, may four times the amount in another unprotected town, viz., Dublin, appear such an irresistible proof that no one "whose mind is not already biased by a foregone conclusion" can fail to be convinced that the difference of disease was solely due to the absence of protection.

Now, I commenced this inquiry into not six months' disease in a small picked regiment, but into twelve years' disease throughout the whole army and navy, with the impression, like Mr. Ffolliott's, that the sanitary results of the Acts had been favourable; and my "foregone conclusion", therefore, corresponded with his own. But when I found the following amongst many other similar cases, my foregone conclusion was at fault; and I must ask him how he accounts, on his own principles, for the following from the Navy Report for 1870, p. 22. In the same ship, with the same crew, and in the same station, and that a protected one, viz., Portsmouth, the cases of primary syphilis rose from 3 in the first quarter of 1869 to 16 in the last quarter; and fell from 17 in the first quarter of the next year to 1 in the last quarter. Now, if a rise from 1 to 4 in his cases is an unquestionable proof that the increase was due solely to the absence of protection in Dublin, what was the increase from 1 to 5 due to in Portsmouth? And, if nobody but "a person with a foregone conclusion" can resist conviction from such a difference as 4 to 1 between a protected and an unprotected station, what will be said by an unbiased and perfectly impartial person to the difference of 17 to 1 in the same protected station throughout?

The fact is, as Mr. Lawson most truthfully expresses it in his letter to the *Medical Times and Gazette*, December 26th, 1874, "no weight can be attached to the ratios of attacks for single years at small stations, when the whole or the greater part of the force employed may have belonged to a single regiment"; and Mr. Ffolliott must take larger numbers and longer periods of time before he is justified in assuming that only determined and invincible prejudice can fail to be convinced by the results from five or six hundred men for half a year.

In reply to Mr. Lawson, who refers me to his criticism of one portion of my "statement" in the *Medical Times and Gazette* of December 26th, 1874; the bulk of that criticism is occupied upon the following paragraph in my "statement". "Such, then, is the nature of the error, sometimes raising and sometimes lowering the averages, which influence every year in the tables (except the last, in which there were no transfers from one table to another), and renders the conclusions drawn in the Parkes papers as to the influence of the Acts upon these two sets of stations so fallacious as to be without value, including the sanitary question at issue between the advocates and the opponents of the Acts." Mr. Lawson contends that the ultimate result of the process described above as erroneous and fallacious was not unfair, but was practically true, and, therefore, ought not to be objected to. Unfairness is nowhere imputed; and, as he does not disprove the fallaciousness of the process in itself, and as the battle is now being fought upon other grounds than the fallaciousness or otherwise of a particular process, it is not necessary to pursue this particular subject in this correspondence.

The following are the objections (to which Mr. Lawson does not reply) to classing the 14 subjected stations together and the 14 unsubjected, and then comparing them as if they corresponded in every respect, except that one set is under the Acts and the other is not.

1. The stations differ so widely from one another, that, for all other health purposes, Dr. Balfour divides them into eight separate classes in the Army Report, because they cannot be classed together.

2. The ratio of disease has been so widely different from the first in different stations as to make it impossible to compare them together; for example, 81 per 1,000 in Aldershot, and 120 per 1,000 in Dublin in 1860, before the Act was in force.

3. The variable amount of disease in the large manufacturing towns which are all "not" under the Act, compared with the military towns which are "under the Act", is shown by the extreme fluctuations of disease in one class of towns (up a hundred one year, and down a hundred the next) compared with the other, long before the Act was passed—a characteristic difference which still continues, and makes comparison impossible.

4. The large ratio of fall in disease in the military towns, compared with the small fall in the manufacturing towns, years before the Act was passed, showed the existence of some agency in the one set of places which did not operate in the other, quite independently of the

Act, which was not in existence, and made subsequent comparison impossible. For the continued reduction of disease is attributed by the opponents of the Acts to a continuance of causes operating before, whilst the advocates of the Acts claim the whole of the difference as the result of the Acts; as if there had been no substantial reduction in disease and no notable difference in amount between the manufacturing and the military towns before the Act was passed.

The fact is, moreover, that the fourteen protected stations have each such distinguishing characteristics that any mode of classing even them together into one set will be open to valid objections on one side or the other; and until the War Office supplies the statistics which are not contained in the Army Reports for 1860, '61, '62, and '63, the influence of the Acts upon primary venereal sores in the subjected and unsubjected stations must be left in suspense. It is acknowledged in the latest Army Reports that gonorrhoea is higher in the subjected than in the unsubjected stations; and, whilst secondary syphilis was rapidly and steadily declining throughout the army for six years before the Acts, it has risen by an average of a twelfth since they were in force, though the Army Returns do not afford any means of judging whether this rise is most marked in the subjected or the unsubjected stations. The one question of primary venereal sores remains to be settled by the information for which we are looking from the War Office; and, until it is supplied, the subject is, to a great extent, conjectural.

Dr. Parkes's statistics of single selected regiments (judging from Mr. Lowndes's recent letter) appear to be claimed as the battle-field which is to decide the question by the advocates of the Acts; and the answer to them must be postponed, as you are already aware that some engraving is necessary for their illustration, which requires time for its completion.—Yours faithfully,

J. BIRKBECK NEVINS, M.D.Lond.

Liverpool, March 5th, 1875.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

IRISH POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE following circular, marked "Important", has this week been issued to the district medical officers in Ireland.

1, Harrington Terrace, Dublin, March 6th, 1875.

My dear Sir,—As usual, it is my duty to direct the notice of the members of this Association to the business already laid before Parliament for the present session, much of which is calculated to affect the medical profession, and more especially those gentlemen who are connected with the Poor-law Medical Service. I would direct your attention to the notice of motion of Mr. Secretary Cross for the introduction of a Bill "for the Improvement of the Dwellings of the Working Classes in Large Towns". The Chancellor of the Exchequer also will bring in a Bill to amend the law relating to Friendly Societies. Mr. Selater-Booth will introduce a Bill to consolidate and amend the Acts relating to Public Health, England (Ireland?); also to repeal the Adulteration of Food Acts, and to make better provision for the sale of food and drugs. A Building Societies Bill will be introduced this year; and a County Boundaries Bill, which might be made applicable to the squaring of dispensary districts as well. A Bill to promote the erecting and improvement of dwellings for agricultural labourers in Ireland will be brought in by Mr. Bruen, M.P. for Carlow county. Upon the subject of the character of the agricultural labourers' habitations in Ireland, it would be, of course, quite unnecessary for me to attempt to offer you any information; but I may quote an observation lately made by His Excellency the Duke of Abercorn at the Lord Mayor's banquet; viz.: "I am strongly of opinion that the unsuitable dwellings of the agricultural labourer in this country is the strongest reason for his desire to seek his fortune in a foreign land; and I trust that, simultaneously with the increase of wages, a more suitable style of dwelling, a style more in accordance with the rising wealth of the country, may be the future of the agricultural labourers of this country." It is now very generally admitted by statisticians that, owing to the want of proper accommodation for agricultural labourers in Ireland, and the consequent overcrowding, that the real death-rate of this country, even in rural districts, is higher than in either England or Scotland, and very much higher in urban districts in Ireland than in those of the sister countries, with the exception of one or two of the cities in the most populous manufacturing districts. Yet it is asserted that the dispensary medical officer has but little additional duty to perform in his capacity as sanitary officer of his district, although it is well known that this discrepancy in the death-rates of the various por-

tions of the United Kingdom is almost entirely due to zymotic or preventable disease (the aversion of which is the very object of the Public Health Act), as well as the fact that, in the performance of the duties of sanitary officer, he is liable to come into collision occasionally with certain of the sanitary authorities who might, perhaps, be in such a position as would enable them to make the office untenable: a fact that, it is to be hoped, will ultimately cause the Poor-law Medical Service to be made a branch of the Civil Service Department, possessed of its advantages, and paid out of the National Exchequer, instead of from local funds.

With regard to the Public Health (Ireland) Act, I may mention that, from numerous letters I have received upon the subject, the Poor-law Medical Service consider that the medical profession, in all its branches in this country, took a most enlightened view of this most important and vital question, assisted in its furtherance in every way, not only with advice, but at very considerable expenditure. This assistance, however, does not appear to be reciprocated by those most interested in the question—namely, the sanitary authorities—if we may judge from the statements daily appearing in the press, and the salaries proposed to be awarded to the various sanitary officers. The latter are based upon a scale much lower than those in other parts of the United Kingdom, and, it is feared, are not by any means calculated to produce a direct interest in sanitation amongst sanitary officers, considering the dangers and difficulties they will be required to undergo in the performance of their arduous duties. Whether the remark of Professor Haughton of Trinity College, Dublin, upon a recent occasion—namely, that it is notorious that the medical officers of the Poor-law Medical Service in Ireland are not paid sufficiently well as it is, and that the proposed additional remuneration for the imposed additional labour will hardly obtain "willing" labourers—is possessed of a very considerable amount of truth or not, it is not for me to instruct you. In the passage of this very valuable Act through Parliament, it is due to both the Colleges of Physicians and Surgeons in Ireland, to the Irish Medical Association, and to the Irish Poor-law Medical Officers' Association, to mention that every facility was afforded towards its success. The British Medical Association also gave most valuable assistance. It is hardly necessary for me to allude to the advantages which we gained from the experience and advice of the chairman of their Parliamentary Committee—the editor of the BRITISH MEDICAL JOURNAL, Mr. Ernest Hart.

Under the Public Health (Ireland) Act, the organisation of medical officers of health is complete. The chaotic condition of sanitary legislation, however, is so confusing and uncertain, that it throws a great difficulty in the way, and it sadly requires consolidation, if not regeneration.

It has been stated that the medical officers of health in Ireland do not understand the subject of hygiene. It might have been said, with more truth, that heretofore they were not called upon to act on it, and that now that a Health Act has become law, they are rather obstructed than otherwise in carrying out its objects. (I may mention here that some excellent works upon hygiene have been already published; the eminent medical publishing firm of Messrs. Fannin and Co., Grafton Street, Dublin, will, I have no doubt, give any information upon this subject required.)

These obstructions are of a threefold character under this Act:—1. Their employers and masters are those with whom the sanitary officers are most likely to come into collision; 2. They may not find it to be for their interest to come into collision with the powers that be; 3. They will find that they will not always be supported for this collision.

It has been very freely stated that it is a matter of regret that the Local Government Board of Ireland do not treat the Irish Poor-law Medical Service of Ireland as liberally as the medical sanitary officers of England and Scotland are at present. These duties have been imposed upon the Irish Branch of the Poor-law Medical Service, *nolens volens*. Yet they are informed that their remuneration cannot exceed one-fourth of their present salary: this rule does not appear to exist in either of the sister countries. And, as I have been requested to state by a great many informants that the increased price of everything connected with the maintenance of a family has, within the last few years, been so great, that an addition of one-fourth of the present salary would not place it upon the same status that it was some ten years ago, independently of the trouble and risk of this imposed duty.

It is worthy of consideration why the medical profession in Ireland are not treated as fairly as those in the sister countries, and this more particularly affects the Poor-law Medical Service; and, if an opportunity be afforded you, you might ask your Parliamentary representative the reason why. In Ireland, the maximum is ordained, and in England and Scotland the minimum. For instance, for the committal of dangerous lunatics, the maximum in Ireland is "without fee or

reward"; in England and Scotland, there is a minimum fee, and it is not limited. For vaccination in Ireland, the maximum fee is one shilling; in England, the minimum fee is one shilling and sixpence; it is not limited; and, by the last report of the Local Government Board, it was three shillings for each successful vaccination, irrespective of donations. There is no provision for the payment of medical witnesses in courts of law in Ireland, or in the coroners' courts, as there is in England; and there are many other disadvantages that our profession labours under in this country, which you might also bring under the notice of your member of Parliament. I think I could also adduce other instances, if necessary.

In order to remedy this grievance, it is recommended that the whole of the profession should take a broad view of the question, and that it should be sought for: that the various great services should be represented upon the General Council of Medical Education and Registration, and also upon the Council of the British Medical Association. The several colleges, societies, and faculties merely are now represented. These, we do not believe, are in a position to take any interest in their alumni after they have passed through their curriculum. The gentlemen, therefore, who wholly contribute to the funds and expenditure of this body do not appear to be adequately represented, if at all.

We think that the Poor-law Medical Service of the three countries should be represented upon the General Medical Council, and the Army and Naval Medical Service as well.

The Poor-law Medical Service in Ireland numbers somewhere about 1,000 medical men, or one-half of the profession: England and Wales, nearly 5,000; Scotland, about 1,000; in all, close upon 7,000 medical officers. The Army Medical Service numbers over 1,000 men, and the naval about the same. In fact, nearly one-half of the medical men in the United Kingdom are engaged in the public medical services. This arrangement would enable us, through skilled experts, to place our present grievances before Parliament, and, perhaps, prevent future grievances—a matter which we endeavour to keep always before you.

These are matters to which I am instructed to direct your particular attention during the present session.

I may mention, that our treasurer, Dr. Speedy, informs me that the Association is indebted to the amount of about £30. It would be of great importance that this should be paid off at once, in order to carry on the Association. I would, therefore, ask you, if you have not already joined it, to do so; if you are a member, it would oblige by your letting him have your subscription at your earliest convenience.

I remain, yours very truly,

D. TOLER T. MAUNSELL, Hon. Sec.,
Irish Poor-law Medical Officers' Association.

POOR-LAW MEDICAL APPOINTMENTS.

BENNETT, C., M.R.C.S., has been reappointed Medical Officer for the Second District of the Daventry Union.

CREAN, Richard, L.K.Q.C.P.I., appointed Medical Officer for the Township of Cheetham, *vice* J. Hunstone, M.R.C.S., resigned.

GODFREY, T., M.R.C.S., has been appointed Medical Officer for the First District and the Workhouse of the Mansfield Union, *vice* N. Cooper, M.R.C.S., resigned.

HUNT, A. D., M.R.C.S., has been appointed Medical Officer for the Chagford District of the Okehampton Union.

SIMPSON, W. S., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Pontefract Union, *vice* H. Muscroft, L.R.C.P. Lond., M.D., resigned.

SMITH, John Grant, L.R.C.S. Ed., appointed Medical Officer and Public Vaccinator for the Parish of Reay, Caithness-shire, *vice* W. Bruce, M.D., deceased.

SUTHERLAND, D. M'Gregor, M.D., appointed Medical Officer and Public Vaccinator for the Parish of Duonett, Caithness-shire, *vice* W. Bruce, M.D., deceased.

MILITARY AND NAVAL MEDICAL SERVICES.

MINISTERIAL EXPLANATIONS.

IN the House of Commons on Monday night, Dr. Lyon Playfair asked the Secretary of State for War some questions which naturally followed from the observations which we recently made on the result of the recent examinations, whether it was true that there were only eleven candidates for the last army medical examination? how many vacancies there were to fill up? and if it was true that the highest on the list for the army medical service only obtained sixty-four marks beyond the last of the successful candidates in the Indian medical service. To these questions, Mr. Hardy replied that it was true there were only eleven candidates, and that there were no vacancies; in fact, that there were now seven officers in excess of the establishment. We find it difficult to understand Mr. Hardy's statement as to the fact of there being no vacancies; and a reference to the following statement will show the cause of our dilemma. Losses to army medical department

during the past twelve months are—*Dead*: Surgeons-general, 3; Deputy Surgeon-General, 1; Surgeons-Major, 6. *Half-pay*: Director-General, 1; Surgeons-Major, 23; Surgeons, 18. *Resigned*: Surgeon, 1. *Transferred to African Branch*: Surgeons, 2.—Total, 55. The corresponding gains to the Army Medical Department during the same period were:—*Brought in from half-pay*: Surgeons-Major, 2; Surgeons, 5. *Gazetted*: Surgeons, 16. *Now at Vetley*: Surgeons, 8. *Transferred from African Branch*: Surgeon-Major, 1.—Total, 32. Making loss, 55; gain, 32. Balance (loss), 23. It therefore appears that, notwithstanding Mr. Hardy's assertion that there are no vacancies in the Army Medical Department, yet the Department is 23 below what it was twelve months ago; and the Army Estimates (Vote 4) do not show any reduction whatever. It is stated, however, in explanation of this apparent contradiction, that the Department is being reduced in a quiet and concealed manner, so as to avoid the just and natural expostulations to be expected from the officers of the Department. If this be so, it affords matter for just complaint; and it is very desirable that an independent member should afford Mr. Hardy opportunity for further explanation on the subject when the Army Estimates come up for discussion.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, March 11th.

Unqualified Naval Surgeons.—Sir C. ADDERLEY, in reply to Captain Pim, said no unqualified British subject was allowed to sign ships' articles as a surgeon.

Friday, March 12th.

Proposed Fever Hospital at Hampstead.—Mr. COOPE gave notice that on the 9th of April he would call attention to the action of the Metropolitan Asylums Board, with respect to the proposed erection of a fever hospital at Hampstead, and move that a select committee be appointed to consider and report upon the subject.

Lunatic Paupers in Scotland.—Captain HOME asked the Chancellor of the Exchequer whether he contemplated extending to England the same relief granted for the maintenance of lunatic paupers in lunatic wards of workhouses, as had been recently promised for similar cases in Scotland.—The CHANCELLOR of the EXCHEQUER said it was not quite correct to speak of a provision having been "promised for similar cases in Scotland". There was no similarity between the cases in the two countries. In Scotland the cases were under the direct control of the Commissioners of Lunacy, which was not the case in England. He could not, therefore, undertake to extend the same regulations to the two countries.

The Outbreak of Diphtheria at Woolwich.—Mr. G. HARDY, in reply to Mr. SHERIFF, said the outbreak of diphtheria at Woolwich took place in November last, and was not confined to the cottages, although the disease assumed a bad form in them. In Woolwich itself there were eight or ten cases, nearly all of which were fatal, and out of thirty-five cases in the cottages, fifteen were fatal, so that the proportion of fatal cases was greater in the town than in the cottages. Certain remedial measures were recommended, such as throwing two rooms into one, cementing the walls, etc. These did not appear to have been sufficient to stop the progress of the disease, because there had been another outbreak within the last few days. Further investigation had been made into the matter this morning, and it was now recommended that no further progress should be made with the remedial works at first proposed. It was therefore intended to remove the 49th and 50th brigade depôts from Woolwich.

Monday, March 15th.

Medical Service of the British Army.—Mr. HARDY, in reply to Dr. Playfair, said it was quite correct that on the last occasion only eleven candidates offered themselves to compete for the vacancies in the medical service of the British army. There were no vacancies at present. It was quite true that the first of the eight successful candidates in the competition for the Indian medical service had only 84 marks beyond the last of the 20 unsuccessful candidates, but the eight candidates selected were well qualified for the posts they were elected to fill. The first candidate for the British army in 1873 had 2318 marks, against 2105 for the first Indian candidate. This showed that the numbers varied sometimes, but generally India had the advantage.

Notices.—The following notices have been given:—*Ships' Surgeons*: Captain Pim. Return of the names, ages, and nationalities of those persons who have been permitted to serve on the articles of British ships as surgeons, but who are not possessed of a diploma or other qualification required by Act of Parliament.—*Mining Villages*: Mr. Macdonald. To call attention to the sanitary condition of the mining villages of

England, Scotland, and Wales, and the tenure by which the houses are held by the workmen; and to move a resolution on the subject.—*Coroners' (Ireland) Bill*: Mr. Meldon. After second reading (May 12th) to move, That it be referred to a Select Committee, with an instruction to inquire into the expediency of amending the law relating to coroners in Ireland, and to report thereon.—*Adulteration of Food and Drugs (re-committed) Bill*: in Committee: Mr. Pell. Clause 19, page 5, line 26, after "result", insert "together with the sums paid to him", and at end add, "And every such authority shall annually transmit to the Local Government Board, at such time and in such form as the Board shall direct, a certified copy of the number of articles analysed, and shall be entitled to receive the sum of two shillings and sixpence, out of moneys to be provided by Parliament, in respect of every analysis, to be applied towards the expense of executing this Act."—Mr. Thomas Hill. Schedule, page 9, line 24, at end of note add, "in the case of a certificate regarding milk, butter, or any article liable to decomposition, the analyst shall specially report whether any change had taken place in the constitution of the article that would interfere with the analysis."—*Artisans' Dwellings' Bill*: The following are the principal amendments proposed:—Mr. Muntz. That it is expedient to make such provisions in the Bill as would allow purchasers or lessees of areas, referred to in Clauses 5 and 7, to provide accommodation for persons of the working classes to be displaced in such areas, in such places other than the areas, as might after due investigation be sanctioned by the local authorities.—Mr. Cawley. Clause 3, page 2, line 17, after "where" insert "this Act is in force, it shall the duty of the sanitary authority to divide the sanitary district under their control into such number of subdistricts as may be necessary, in order to show the comparative death-rate in the several portions of the district, regard being had to the character of the dwellings therein, and to publish quarterly and annual returns, showing the number of deaths in each subdistrict, and the proportion of deaths to the number of persons living therein; and in every case in which the death-rate shall exceed the average of that of the whole district, it shall be the duty of the sanitary authority to inquire into the causes of such excessive death-rate; and the medical officer of health shall, in every such case, report to the sanitary authority his opinion as to the cause or combination of causes of such excessive death-rate; and if it should appear that such excessive death-rate is in any degree due to imperfect, defective, or improper sanitary arrangements, it shall be the duty of the sanitary authority to cause all such defects to be removed, and such alterations to be made as may be necessary, in order to comply with the provisions of any Act or Acts in force within such district."—Mr. Kay-Shuttleworth. To add: "The Local Government Board may, at any time, send one or more medical officer or officers to make a special inquiry into the sanitary condition of any part of any urban sanitary district, who may make an official representation, and such representation shall have the same incidents as if made by the medical officer of health of such authority."—Mr. Muntz: That it is expedient to make such provisions in the Bill as would allow purchasers or lessees to provide accommodation for the working classes who may be displaced.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council on February 25th, the following members were elected Fellows.

Messrs. Alfred George Roper, I. S. A., Northend, Croydon; and Peter Broome Giles, I. S. A., of Staunton-on-Wyre, Hereford, their diplomas of membership of the College bearing date respectively October 9th and December 14th, 1874.

APOTHECARIES' HALL.—The following gentleman passed his examination in the science and practice of medicine, and received a certificate to practise, on Thursday, March 11th, 1875.

Sworder, Horace, St. Mary's Hospital, Holly House, Luton, Beds.

The following gentleman also on the same day passed his primary professional examination.

Counbe, John Batten, St. Mary's Hospital.

MEDICAL VACANCIES.

THE following vacancies are announced:—

BANTRY UNION—Medical Officer for the Workhouse. Salary, £50 per annum. Applications to be made on or before the 24th instant. Medical Officer for the Bantry Dispensary District. Salary, £100 per annum, and fees. Applications on or before the 24th instant.

BECKETT HOSPITAL AND DISPENSARY, Barnsley—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.

BIRKENHEAD BOROUGH HOSPITAL—Senior House-Surgeon. Salary, £100 per annum, with board. Applications on or before the 22nd instant.

BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.

BRADFELD UNION—Medical Officer for the Fifth District. Salary, £53 rs. 8d., and fees. Applications on or before April 6th.—Resident Medical Officer. Applications to be made on or before April 2nd.

BRISTOL LUNATIC ASYLUM—Assistant Medical Superintendent.

CHARING CROSS HOSPITAL—Resident Medical Officer. Applications on or before the 24th instant.

CLIFTON UNION—Medical Officer for No. 3 District. Salary, £25 per annum. COVENTRY AND WARWICKSHIRE HOSPITAL—House-Surgeon and Dispenser. Salary, £100 per annum, with board, lodging, and attendance. Applications to be made on or before the 25th inst.

DEVON AND EXETER HOSPITAL—House-Surgeon. Salary, £150 per annum, with board.

DOVER UNION—Medical Officer for the St. Mary's District and the Workhouse. Salary, £180 per annum.

DURHAM COUNTY ASYLUM—Assistant Medical Officer.

FARRINGTON GENERAL DISPENSARY AND LYING-IN CHARITY—Two Physicians. Applications on or before the 27th inst.

FETTERCAIRN, Parish of—Medical Officer and Public Vaccinator. Apply to Colonel M'Invoy, Chairman of the Board, The Burn, Brechin, not later than the 27th inst.

HALLEFAX UNION—Medical Officer for the Southwam District. Salary, £50.

HENSTEAD UNION—Medical Officer for the Second District.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST—Resident Clinical Assistant. Applications on or before April 5th.

KINGSTON, Jamaica—Two Medical Officers for the Public Hospital.

LIVERPOOL ROYAL INFIRMARY—Resident Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications on or before April 10th.

MANSFIELD UNION—Medical Officer for the Fifth District. Salary, £32 10s.

MILFORD UNION, co. Donegal—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.

POOLE UNION—Medical Officer for No. 2 District. Salary, £60 per annum.

QUEEN ADELAIDE'S DISPENSARY, Bethnal Green—House-Surgeon. Salary, £100 per annum, with furnished apartments, coals, and light. Applications on or before April 1st.

QUEEN'S HOSPITAL, Birmingham—House-Surgeon and Dispenser. Applications on or before the 25th inst.

ROYAL EDINBURGH ASYLUM—Assistant-Physician.

ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road—Physician.

SEAMEN'S HOSPITAL, Greenwich—House-Surgeon. Salary, £100 per annum, with furnished apartments. Applications on or before the 24th instant.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.

ST. THOMAS'S HOSPITAL—Assistant Obstetric Physician. Applications on or before the 24th instant.

SOUTH ESSEX DISPENSARY—Surgeon.

SOUTH SHIELDS UNION—Medical Officer for the Westoe District. Salary, £40 per annum.

SPILSBY UNION—Medical Officer for the Spilbsy East District. Salary, £40.

STRATTON UNION—Medical Officer for No. 3 District. Salary, £70 per annum.

TORREY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.

WESTMINSTER HOSPITAL—House-Physician. Applications on or before April 5th.

WEST NORFOLK AND LYNN HOSPITAL—Resident Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 30th inst.

WEST BROMWICH DISTRICT HOSPITAL—Salary, £80 per annum, with board, lodging, and washing. Applications on or before the 22nd inst.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL—House-Surgeon. Salary, £100 per annum, with board, washing, and furnished apartments. Applications on or before May 3rd.

WORCESTER AND CITY LUNATIC ASYLUM, Towick—Assistant Medical Officer. Applications on or before April 5th.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

*Coe, Robert W., F.R.C.S. Eng., appointed Consulting Surgeon to the Bristol General Hospital.

Fry, John F., L.R.C.P. Lond., appointed House-Physician to Guy's Hospital.

*Garstang, Walter, M.D., appointed Physician to the Blackburn and East Lancashire Infirmary, *vice* E. S. Morley, M.D., resigned.

Greening, Frederick J., M.R.C.S. Eng., appointed Surgeon to the Dispensary, Kyde, *vice* W. B. Wilmet, M.D., deceased.

Hill, J. Wood, L.R.C.P., appointed Surgeon to the Western District of the Chelsea, Brompton, and Belgrave Dispensary.

Johnston, John, M.R.C., appointed Resident Medical Officer to the Birmingham and Midland Free Hospital for Sick Children, *vice* M. A. Bessier, M.R.C.S. Eng., resigned.

*Krahl, William P., L.R.C.P. Ed., appointed Surgeon to the Bristol General Hospital, *vice* R. W. Coe, F.R.C.S. Eng., resigned.

*Lord, Charles F. J., M.R.C.S. Eng., appointed Consulting Medical Officer to the Hampstead Provident Dispensary.

*Ronson, Robert N., M.R.C.S. Eng., appointed Surgeon to the Durham County Hospital.

Secombe, George S., L.R.C.P. Lond., appointed Assistant Medical Officer to the Metropolitan District Asylum for Lunatics at Caterham, *vice* E. G. Younger, L.R.C.P. Lond.

Shearer, George, M.D., appointed a Medical Officer to the North Dispensary, Liverpool.

Steeple, John W., M.D., appointed a Medical Officer to the East Dispensary, Liverpool.

Younger, Edward G., L.R.C.P. Lond., appointed Apothecary to the Middlesex County Asylum, Hanwell.

BEQUEST.—Miss Sarah O'Farrell, late of Merrion Square, Dublin, has bequeathed £5,000 to St. Vincent's Hospital in that city; the testator also devised her house for the benefit of the same hospital.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8 P.M. Clinical Evening. Mr. Gant, "Epithelioma of the Tongue, with Laryngoscopic Illustration": Dr. Theodore Williams, "On a Case of Arrested Phthisis, in which Complete Contraction of a Tinkling Cavity took place": Dr. Broadbent, "Illustrations of different Forms of Uremic Poisoning".

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. Walter Rivington, "Case of Pulsating Tumour of the Left Orbit, cured by Ligation of the Left Common Carotid Artery: with a *Résumé* of recorded Cases of Intraorbital Aneurism".

WEDNESDAY.—Hunterian Society, 8 P.M. A General Meeting.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

ACIDITY OF THE STOMACH.

SIR,—A correspondent in your last issue asks for a remedy for this, states all the ordinary ones having failed. I would suggest a very old one, which has often proved successful. It consists of equal parts of assaefetida and ox-gall, made into pills, and taken in full doses three times a day. A scruple of each should, at least, be used daily. Need I remind your correspondent of the different effects, in this state, between animal and vegetable food?—I am, Sir, yours,

H. KENNEDY.

M.D.—If the cause of death be not clear to a practitioner in attendance without *post mortem* examination, he would, we apprehend, refuse to make what would possibly be an erroneous guess. If urgently called upon to fill in a certificate in accordance with the terms of the Act of Parliament, he would state death to have occurred from "internal disease, nature uncertain"; whereupon a *post mortem* examination would probably be ordered, and the certificate returned for further particulars.

THE MEDICAL BENEVOLENT FUND.

MR. JAMES MORRIS, (Dunfermline), in forwarding an annual subscription of a guinea to this fund, through the General Secretary of the British Medical Association, writes as follows.

"I am very anxious that this fund should be well supported, but am afraid unless some special action is taken it will never rise to that position the profession has a right to expect. If the JOURNAL or some man of note would take up the subject and keep it before the profession, or if any one could be persuaded to read a paper at the Annual Meeting, good might come out of it. If the whole profession could be led to see the importance of such a subject, and could be induced to give 1 per cent. of their income for one year, it would realise about £100,000—a splendid amount to begin with—which would enable the acting committee to do full justice to old or disabled brethren in want, or widows and orphans in connection with the profession. Unless some such general plan as this is adopted, I am afraid the Benevolent Fund will never be in a position to meet all the wants of the profession. Trusting that you or some one through your influence will take up and ventilate this matter,—I am, etc.,

JAS. MORRIS.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

THE SOUTH HANTS DISTRICT MEETING.

SIR,—Permit me to correct a slight error which has crept into the report of the late meeting of the South Hants District of the Southern Branch. The specimens of membranes I exhibited were not fibrous exudations as stated, but, as I was very careful to insist on in my paper, true examples of the exfoliated lining membrane of the uterus, showing under the microscope the utricular glands. —

Faithfully yours,

W. H. AXFORD.

SUPERFETATION.

SIR,—I lately attended Mrs. W., a healthy young woman, in her second confinement. The baby was born before my arrival; the placenta followed in the usual way, and the uterus contracted normally. There was no indication of any unusual circumstances in the case, which progressed favourably. The patient suffered little or no after-pains; but forty-eight hours after delivery, she became conscious of the presence of some foreign body, and there presently passed, without difficulty, the unmistakable proofs of a second conception. Fœtal development was apparently two months advanced—the rudimentary placenta, etc., being present.

I could supply further particulars, which would, I think, convince your readers (if sceptical) that the case recorded was one of superfetation, though I know many powerful arguments could be opposed to this theory.—I am, etc.,

Littlehampton, March 6th, 1875.

H. J. KENDRICK VINES.

ARCHÆOLOGIST.—Mr. Joseph Warner was a member of the Court of Assistants of the College of Surgeons in 1800. With the family estate, he inherited a ring, famous in history as the one given by Queen Elizabeth to the Earl of Essex, and which the Countess of Nottingham never delivered to the Queen.

THE CONTAGIOUS DISEASES ACTS.

SIR,—I have only now become aware of the publication in the JOURNAL of the 6th inst., of what purports to be a correction of statements made by myself in a letter published on the previous Saturday. Your informant says that I am under a misapprehension in stating that the five members of the Liverpool Royal Infirmary School of Medicine who did not sign the memorial concerning the Contagious Diseases Acts, "constitute more than one-third of the entire staff", and then goes on to add that, of the five non-signers, three are not medical practitioners. This is an absolute, and as it seems to me, most careless error on the part of your informant, for a moment's inquiry from me would have elicited the information which I have now to give, viz., that every one of those alluded to by me as not signing is a medical man in active practice. I should have considered it to be as improper on my part to include among those who did not sign, gentlemen whom the very terms of the memorial—viz., "we the undersigned medical practitioners"—altogether excluded from signing, as I do on your correspondent's part to include them on the staff. If I had considered them as forming part of the staff contemplated by the memorial, I should have had to reckon them as not signing, and it would then have made the numbers of those who signed and did not sign almost precisely equal. But I felt that this would not be fair. I now repeat that the entire staff who were capable of signing the memorial comprised fourteen and only fourteen members, twelve lecturers and two demonstrators; that of this number, five lecturers, viz., those on materia medica, medical jurisprudence, children's diseases, physiology, and botany, respectively, did not sign; and that five are more than one-third of fourteen.—I am, etc.,

WILLIAM CARTER, M.D.

74, Rodney Street, Liverpool, March 13th, 1875.

* * The total number of gentlemen on the staff of the Royal Infirmary School of Medicine is seventeen. Of these, three (Messrs. Brown, Snape, and Swart), are not medical practitioners, and were not asked to sign the memorial. Of the remaining fourteen, three (Drs. Nevins, Whittle, and Carter), being well-known opponents of the Acts, were also not asked to sign. Of the remaining eleven, only two refused (Drs. Caton and Gee), but not because they were opposed to the Acts. The numbers, therefore, are strictly nine in favour of the Acts, three against.

COTTAGE TREATMENT OF THE INSANE.

SIR,—I shall feel much indebted if you or any of your readers will oblige by informing me—1. Whether the "cottage system" of treatment for the cure of the insane is carried out in any part of the United Kingdom or of the Continent under the management of English speaking people? 2. Whether in any or all of the localities in which this system is pursued the houses in which the patients are domiciled are subjected to regular inspection by competent and respectable officers? or is any other efficient method of supervision exercised over their management, so as to preclude the danger of capricious severity, insufficient dietary, or other harsh or injudicious treatment? 3. Whether in any published work on the subject, the items of information which I desire are supplied.—I remain, yours respectfully,

CARDEL.

* * We referred the above communication to Dr. Batty Tuke of Edinburgh, who kindly writes to us as follows.

"The 'cottage system' of treatment of chronic lunatics is carried out extensively in Scotland, and with considerable success. About 1,200 lunatics are provided for in this way. The machinery for supervision is as follows: 1. A yearly visit from a deputy commissioner in lunacy; 2. Occasional visitation by the inspector of poor (relieving officer) of the parish to which the lunatics are chargeable; 3. When necessary, a visit by the local medical officer. The deputy commissioner reports to the General Board of Lunacy, and has considerable powers as to the removal and disposal of the patients. In Scotland, there are some two or three colonies—one at Balfour in Stirlingshire, and another at Kennoway in Fife-shire. There are some smaller ones, but those named are the most important. In each, from thirty to forty lunatics live in the houses of the villagers, and on the whole are well provided for. Full information on the subject will be found in the blue-books of the Scottish General Board of Lunacy; and Dr. Arthur Mitchell, Commissioner in Lunacy, would, I am sure, be only too happy to supply further details. Although in my individual opinion the supervision is not sufficient, and is quite capable of improvement, I regard the 'cottage system' as a most important and valuable method of providing for the insane poor. I send you herewith copies of two papers I wrote on the subject. Since the larger one was written, great improvements have been effected at Kennoway, the village described. I must confess that in it the system is now fairly worked. The great results of the system are these: 1. The county asylums are relieved by the removal of chronic harmless cases, and so the necessity of constant additional buildings is obviated. 2. There

is some saving of maintenance of lunatics. From 4s. to 6s. per week is the sum charged; in addition to which, clothing and bedding are found by the parish. 3. Some patients improve. But the chief good result is the *check the system affords to the overgrowth of asylums*. Tell your correspondent that my paper does not quite represent my present views on the subject, except so far as it applies to the proposed machinery for inspection. I still think the superintendent of the county asylum should be the district inspector. This would assure against all abuses, or at least would do so as far as possible. If the 'cottage system' had not been at work when I was superintendent of the Fife and Kinross District Asylum, it would have been absolutely necessary to have enlarged the accommodation; but I found that the admissions were balanced by cures, deaths, and the removal of improved and harmless cases to private dwellings. I feel confident that the 'cottage system' affords the only solution of the great difficulty in lunacy. An overgrown asylum—i.e., an asylum for more than 400 patients—is a great social evil, it is a manufactory of dementia and chronic lunacy. Practice shows the system to be feasible, but practice also shows that it is capable of improvement. I shall be happy to afford any further information to your correspondent."

MEDICAL DEGREES AND TITLES.

SIR.—Your correspondent, M.D. Erlangen, M.R.C.S. and L.S.A., whose letter appears in the JOURNAL for February 13th, omits to mention whether the examination he underwent was conducted in the English or German languages. I can say from experience, that at Würzburg the German language only is used at the examination, which consists of the following stages:—Several days' written examination upon eight subjects; one day's *viva voce* upon the same subjects; the reading of a short paper of medical interest; debating publicly upon two or more medical questions, and finally, the publication of a thesis approved by the examiners. The latter are seven in number, being the professors in the University of the subjects upon which they examine. Certificates are required of at least six sessions' study at a recognised medical school.

Let me now call the attention of your readers to the conditions upon which alone foreign medical degrees are inserted in Messrs. Churchill's *Medical Directory*, they are as follows: 1. That the degree is registered under the Medical Act; or, 2. That the professor has qualified in Great Britain or Ireland, and is practising abroad; or, 3. That the holder of the degree has also a British Qualification, and that his possession of the foreign diploma, and its attainment by examination have been certified to the editor of the *Medical Directory* by two registered practitioners, not themselves possessing foreign degrees. It thus appears that only reputable foreign degrees will be found inserted in this Directory.

I enclose my card, and remain, Sir, yours, etc.,
February 22nd, 1875. M.D., Würzburg, M.R.C.S. and L.R.C.P.E.

SIR.—With your kind permission I will make a few observations on the letter signed "M.D. Edin. and M.A. Dublin," which appeared in the JOURNAL of the 27th ultimo. As to some degrees being higher than others, I firmly maintain that the degrees of the London University undoubtedly stand pre-eminent, and will continue to do so, unless the examinations be made considerably more lenient, and the examinations of other qualifying bodies made comparatively more searching. The degrees of Oxford or Cambridge are not to be considered of more value than those of London, even though the cost of obtaining the former be greater. A degree should be valued by the searching mode and severity of the examinations which have to be undergone before it is obtained, and not by its intrinsic price. The London University is exclusively an examining body, and the candidates for its degrees need not expect to have their teachers for examiners, so, according to your correspondent its examinations are a more accurate test of a man's knowledge, in as much as its examination papers are considerably more difficult than those of any other University in this country. If a man swear by his place of education, let him also swear still stronger by the test which his knowledge gained at such place has undergone.

He also states that an M.D. is no more a physician, than a LL.D. is a barrister, or an M.A. a clergyman. Now, we are all aware that LL.D.s and Q.C.s are appointed barristers to preside over Quarter Sessions in Ireland, then they are legally and officially barristers. But to come to the point concerning the degree of barrister; a doctor in law must be previously a barrister in the same faculty. He is therefore in possession of both degrees, and can add to his name with impunity either he may prefer; and to say that an M.A. is a clergyman, is as absurd as to say that an M.D. is a lawyer. No matter whence the origin of a degree, it always bears with it a distinction, and a letter signed "Student Medicinae," in the JOURNAL of the 20th ultimo, will prove conclusively that if any preference be given, an M.D. is more a physician than a Licentiate of a College. The M.D.s have never coveted the L.R.C.P., neither do they raise any row about the F.R.C.P., because if they want it they can get it by examination; whereas an ungraduated Licentiate cannot. This is another point where the Councils of Colleges place in more confidence in the knowledge of graduates than that of licentiates. You have heretofore, in answer to correspondents, asserted that in the medical profession, the right of the title Doctor is the peculiar property of an M.D. Your correspondent, I am glad to see, admits that "grinding" will pass a man at a College of Physicians, but he very wisely states that moderate diligence, with residence, is required to pass a man at an University. And it does not matter much if persons, whom one meets in society, consider examinations in different tests of knowledge; as a rule, society often ventures opinions on questions with which it is wholly unacquainted.

Now for the question of the judiciousness of a certain British University conferring degrees on existing Licentiates, after a good practical examination. Oxford graduates are perfectly justified in objecting to ungraduated Licentiates obtaining honorary degrees from the University where they—the Oxford graduates—have spent both time, money, and labour, in order to obtain the coveted degree. Your correspondent has no right to expect the London University to lower the status of its graduates, by conferring its degrees upon, I may say, unworthy men. If a man wants a degree from the said University, let him pass the examinations entitling him to such; and if it come to pass that the London University will confer its degrees on the existing Licentiates, after one practical examination, then future medical students need no longer submit to a "string" of severe examinations; they can study where they please, become licentiates, and then, as your correspondent would have it, "graduates of London." Then he says, if the London University do not comply with a petition, such as he mentions, there is still a method of obtaining the coveted letters, by (I think he must mean) having a fixed programme of subjects for matriculation, at this examination in his opinion, is the only obstacle; and he thinks that if this examination, which he terms the asses' bridge, were passed, the remainder of the course would be as easy as elsewhere.

This reminds me very much of the asses' bridge in geometry, the demonstration

and proof of which no doubt confuse the beginner a little, but is only one of many difficulties which have to be surmounted, before the learner can enter upon a higher grade of study. Now, supposing the matriculation to be modified, and the remainder of the bye laws to remain as at present, still licentiates would find it a very difficult and inconvenient matter to obtain the degree. According to the regulations of the London University, the several examinations must be passed not at any time, but at or beyond fixed periods, and between each examination certain lectures must be attended at recognised schools and hospitals for that purpose, even though the candidate be a graduate in medicine of a different University. If he be a graduate in arts, then he can get credit for his degree, and will not have to undergo the matriculation, but will have to commence by passing the preliminary scientific examination. I have considered the matter carefully, and am of opinion that the Scotch Universities are the easiest sources whence a licentiate can obtain the degree—I mean at present, without any reformation of those qualifying bodies, inasmuch as one year's residence is only required. And most graduates will agree with me when I say, that although residence at any particular place is not required by the London University, yet its degree is more difficult to be obtained than any other in the United Kingdom; and I would direct your correspondent's attention especially to the position which London graduates hold, no matter where they settle. He will invariably find them enjoying first-class positions in professional life.

In conclusion, I beg to remark that a gentleman who holds degrees both in arts and in medicine, should not be so innocent of the right which degrees confer upon him. Every man who possesses a respectable degree should be justly proud of it. And every graduate who holds that a licentiate is a doctor is unworthy of his degree, inasmuch as he does not uphold the status of the University of which he is a graduate.

Apologising for this already too long communication,

I remain, Sir, your obedient servant,

George Towa, Merthyr-Tydvil, March 1875. J. LOWE.

MR. BOLLAND.—What a news writer did in England in 1622, on his own responsibility, was effected ten years afterwards in France, under the patronage of Louis XIV, by Theophrastus Renaudot, a member of our profession, who issued the first number of the first French newspaper, viz., the *Gazette de France*, in 1632.

We are indebted to correspondents for the following periodicals, containing news reports, and other matters of medical interest:—The Cork Constitution; The Glasgow Herald; Saunders' News Letter; The Argylshire Herald; The Birmingham Morning News; The Birmingham Daily Post; The Hampshire Telegraph; The Newton Directory; The Sheffield Daily Telegraph; The Berkshire Chronicle; The Hackney Express; The Bath Argus; The Portsmouth Times; The Liverpool Mercury; The Alcester Chronicle; The Hereford Times; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. Headlam Greenhow, London; Dr. R. J. Lee, London; Dr. Aveling, London; Dr. Charlton Bastian, London; Dr. Farquharson, London; Mr. Fairlie Clarke, London; Dr. Robertson, Buxton; Mr. Berkeley Hill, London; Dr. Lionel Beale, London; Dr. Marcet, Nice; Dr. E. Crisp, London; Dr. J. B. Nevins, Liverpool; Dr. Burdon Sanderson, London; Mr. J. Rogers, Swansea; Mr. J. H. Galton, Norwood; Dr. J. P. Caswells, London; Mr. G. Pollock, London; The Secretary of the Joint Counties Lunatic Asylum, Carmarthen; Dr. A. Ford, Bradford; Mr. R. B. Cook, Scarborough; Dr. Tilbury Fox, London; Dr. Humphry, Cambridge; Our Paris Correspondent; Dr. J. Morton, Glasgow; Dr. Procter, York; Mr. Vincent Jackson, Wolverhampton; Mr. D. W. Morris, Llanelli; Mr. Whalley, Southampton; Dr. J. Crichton Browne, Wakefield; Dr. J. Macnaughton, Lochgilphead; Mr. W. Carter, Liverpool; Mr. A. O'Sullivan, Burnley; Dr. C. R. Free, Rhyl; Dr. C. LECTURES

ON

THE OCCURRENCE OF ORGANIC FORMS
IN CONNECTION WITH CONTAGIOUS
AND INFECTIVE DISEASES.*Delivered at Owens College, Manchester.*

BY

J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

LECTURE III.

SPECIFIC CONTAGIA.

IN the last lecture, we entered on the consideration of the question, whether or not, in those cases in which fever is produced by a poison of septic origin, the organisms which associate their life and development with all putrefactive processes, are concerned in the pathological phenomena which manifest themselves. It was shown, on the ground of experiment, that, although pyrogenic liquids in the crude state are septic, and, therefore, contain bacteria in greater or less numbers, it is possible to obtain from them a material of great activity, *leaving behind the microphytes*. In stating this fact, I pointed out that it would afford no ground for denying the influence of bacteria in the production of the morbid material; for, although they may not themselves constitute it, there is nothing in the fact observed which makes it less probable than before that they are concerned in those chemical changes of which its presence is one characteristic. At the close of the lecture, I drew special attention to a fact of great moment, namely, that, in my pellucid pyrogenic liquid, the active principle, although apparently in solution, is really particulate, for it can be separated by an appropriate mode of filtration (filtration through a "porous cell").

To-day we pass to a subject which must be kept apart from the other—that of the relation of microphytes to specific infections. The two questions are distinct by nature, and consequently the modes which have to be employed in their investigation are necessarily different. It is, therefore, desirable to keep them separate. In fever, we have to do with a process—an aggregate of functional disorders, all of which have their seat in the organism. In contagion, we have to account for its effect on ourselves, and also (what is more difficult) for its behaviour outside of us—the wonderful fact that it preserves itself for long periods, and is conveyed to immense distances quite independently of its ultimate destiny.

The doctrine that microphytes have to do with the process of contagion is based on two sorts of observations, viz., those relating to the physical characters of contagious liquids, and those relating to the existence of organisms of characteristic form in them. As regards the physical characters of contagious liquids, the fundamental fact is that contagium is *particulate*. I do not hesitate to use this word, for there is no other which answers the purpose. It stands for the general result of observations made by Chauveau as to the non-diffusibility of the infecting part of a great many contagious liquids, particularly those of small-pox, vaccine, glanders, the so-called small-pox of sheep, or sheep-pox. The method employed by Chauveau in these investigations is now so well known that I need only advert to it very shortly. As a link in the chain of evidence on which the notions we now entertain as to contagium are supported, it is too important to be omitted. The method, like that of which in last lecture we considered the application to the investigation of the fever poison, is one of mechanical analysis. A liquid known to be actively virulent is placed at the bottom of a small test-tube, which stands upright on a foot, or is otherwise supported in the same position, care being taken to avoid the slightest contact between the liquid and the sides. Water is then allowed to flow over the surface of the liquid until it forms a layer a few lines in thickness. The result is that, if the liquid remain absolutely still, diffusion takes place between the liquid and the water. The soluble salts pass into the water, along with a quantity of albumin: everything which is particulate remains below, everything that is diffusible rises. The process differs from that of diffusion through a membrane in this respect, that, whereas in the "diffusion cell" bodies which are very slightly diffusible, such, e.g., as albumin, pass through the membrane in extremely small quantity, so

that practically they may be said to remain behind, in the present case, the only constituent which remains at the bottom consists of particles which, although they are small enough to pass readily through filtering paper and act so little on light that they do not render the liquid turbid, can yet be seen under the higher powers of the microscope. Hence, if the contagium is particulate, it will be found exclusively in the lower layer: if diffusible, it will be in the surface layer of water, albumin, and salts. Experiment showed, as regards all the contagia I have mentioned, that it remained below: and, therefore, was insoluble and indiffusible.

These experiments were made in 1868-9. I became acquainted with them when spending some time at Lyons in the latter year, and afterwards repeated them in London in their application to vaccine. I had previously (in 1866) made analogous experiments on the contagious liquid of Kinderpest, but by another and very inferior method. I had introduced a liquid of known contagiousness into an ordinary diffusion cell, and had observed that the active part did not pass through the parchment-paper septum. This is a bad method, because in this kind of diffusion the albuminous compounds which are very slightly diffusible, are stopped by the septum: so that it might be objected that the toxic agent was contained in the albumin, not in the particles. Indeed, a blunder of this sort has been very recently promulgated by a French writer, M. Onimus.*

On this inference as to the particulate nature of contagium, I founded in 1870, an *a priori* argument in favour of the probability of *contagium animatum*—that is to say, in favour of the doctrine that the property of contagiousness as manifested in contagious morbid products is associated with the presence in such products of particles *which possess a life, which is not that of the tissues of the human or animal subject of disease*. If contagium be conveyed from place to place and maintain its activity in the form of particles, those particles must consist either of bits of protoplasm or of living organisms: for those are the only sorts of particles of which we have any indication in contagious liquids.

Now, considering that of all perishable things protoplasm is among the most perishable—so much so, that no living particle of our bodies can be abstracted from its place in the organism, even for five minutes, without dying and being disintegrated—it appeared to me quite out of the question to suppose, as Dr. Beale had suggested, that the particles could be of this nature, consistently with the astonishing power which they evidently possess of retaining their activity for such long periods, in spite of their being subjected to enormous varieties of moisture, temperature, and all other conditions. And considering that life—i.e., organisation—is the only condition whereby a body of chemically unstable composition is enabled to hold its own against such disintegrating agencies. I thought then, and I still think, that the only possible explanation of this fact of the persistence of contagium was to suppose its particles to be living. Then at once the question arose—"What sort of life is it that they possess?" Two facts help us to conclude in favour of the group of organisms I described in last lecture: first, they are the smallest and simplest of known organic forms; and, secondly, they possess the wonderful property of passing into a state of persistent inactivity or latent vitality, in which they perform no function, but can be at any moment wakened up into active function whenever they are brought under favourable circumstances. If I am asked what ground I have for the statement, that bacteroid microphytes possess the property of latent persistence, I will content myself with drawing your attention to the undisputed facts relating to the inoculation of "test-liquids". If I find that a particle of dust which has remained on the ceiling of the room for some time, when added to a solution of ammoniac tartrate, determines an enormously active vegetation of bacteria in it, I find it difficult not to suppose that the particle of dust contains living material: and inasmuch as I know that, if I examined it under the highest powers, I should see nothing which I could recognise as vegetable by any vital manifestations which it would present to me, I am compelled to express the result of the experiment in some such terms as I have used. Particles are there, which, so long as the dust remains on the ceiling, undergo no changes, manifest no process. You may object that I have no proof that the dust contains anything living. True: but I have proof that it contains that which produces life, and express this state of things: viz., the absence of manifestations of life, on the one hand, and, on the other, the fact, that the stuff in question possesses the power of impregnating something else which before was barren, by saying that the dust possesses latent vitality.

I have now to run over, as briefly as possible, the cases in which observations have been made as to the presence of organisms in contagious products. As vaccine and small-pox have been already mentioned, I will refer to that subject first.

The earliest published observations as to the existence of micro-

* See *London Medical Record*, November 19th, 1873.

phytes in the infective liquids of vaccine and small-pox were those of Hallier and Keber (1868), both of which were made with bad instruments, and attracted less attention than they would otherwise have done from the speculations with which they were associated. My own description of the organisms of vaccine appeared in an appendix to the Twelfth Report of the Medical Officer of the Privy Council in 1870. About the same time, but quite independently, they were much more completely investigated by Cohn, the eminent professor of botany at Breslau.* The description of Cohn agrees entirely with mine: a fact which I think important enough to mention, on account of its bearing on certain statements recently published by Dr. Beale, to which I must refer immediately.

Cohn has given to the organism seen in vaccine the designation of *Microphara Vaccine*. In fresh vaccine, it consists, according to his description, of minute spheroids grouped in couples or isolated. If a preparation of lymph be observed under the microscope on the warm stage, these particles divide repeatedly, and thus resolve themselves into chaplets. By this fact, as well as by their chemical reactions, they are easily recognised as micrococci. There is, I think, no particular reason to doubt the accuracy of the observation, discovered as it was in the first instance by observers working quite independently of each other, and in ignorance of each other's results. I was, therefore, rather surprised that, in a recent work on *Disease-Germs*, Dr. Beale should have criticised my very brief description of these organisms, and particularly the woodcuts with which it is illustrated, in such strong terms as he has employed. I cannot show you my woodcut, but I have placed before you a copy of Cohn's drawing made by a draughtsman. I have also placed on the board an exact representation of Dr. Beale's drawing of the particles in vaccine which he distinguishes as "true disease-germs", in contrast to mine, which he regards as false ones. Be it remembered that I have not asserted that the particles in question are "disease-germs" at all. All that has been stated is, first, that they are independent organisms, and, secondly, that they are to be observed in fresh vaccine.†

Shortly before the appearance of Cohn's first paper, another Breslau observer—a pathologist and hospital physician, not a botanist—published a short communication founded on the microscopical examination of the skin in persons who had died of small-pox, in which he stated that he had found the lymphatic vessels of the cutis plugged with a granular mass which exhibited all the characters of micrococci. These lymphatic vessels were met with for the most part in the tissue of the corium underneath and around pustules in various stages of advancement. Here, in some cases, they occurred so constantly, that they could be found in every vertical section of the skin which comprised a pustule, though they were absent in others.

This statement being founded on a considerable number of cases, is probably well worthy of confidence. It is to be noted with respect to it, that the appearances in question were observed only in cases which terminated early in the disease, *i.e.*, before the seventh day. In more advanced cases, the infiltration of the tissues and the consequent impaction with the cellular products of inflammation, rendered it impossible to make out with certainty whether the vegetations were present.
